THE
ILLUSTRATED
GLOBE ENCYCLOPÆDIA.

Pass'over, as it appears in Jewish history, is a great annual festival celebrated in commemoration of the deliverance of the Israelites from the bondage of Egypt. The name was derived from the destroying angel's *passing over* (Heb. *pesach*) the houses of the Israelites, when he slew the first-born of the Egyptians. At the first institution of the P. each family was to take a lamb or kid under a year old, and kill it on the afternoon (between noon and darkness) of the 14th of the month Nisan; the blood was to be sprinkled on the two side-posts and the lintel of the door, as a sign for the destroying angel; and the animal was to be roasted whole, and eaten that night, with unleavened bread and bitter herbs. The festival was to continue for seven days, during which unleavened bread alone was to be eaten, because the people had to pack up and depart from Egypt in such haste that the dough in their kneading-troughs was not leavened (Exod. xii.). In the instructions for the perpetual observance of the festival there is one important variation from this—namely, that the males were to appear annually for the observance of the P. at the national sanctuary, where the paschal animals were to be slain, and the blood sprinkled on the altar (Leut. xvi. 1-8). Such is the historical account given of what some critics hold to be a compound of two festivals—both pre-Mosaic, and pointing to the primitive Nature-worship which they believe to have prevailed among all the Semitic tribes, according to which the first-fruits of the harvest, as well as of man and beast, belonged to the deity. The festival of Unleavened Bread was observed at the spring equinox, when the first-fruits of the new year (Nisan was the first month) were presented to Jehovah; the first ears of barley being partly offered on the altar and partly ground into flour and baked into sacrificial (and necessarily unleavened) bread (Exod. xxiii. 14-19, Lev. xxiii. 4-14). The Paschal sacrifice (Aram. *pascha*, Heb. *pesach*, passover, exemption) was connected with the redemption of the first-born (see CIRCUMCISION), who, as well as the first-born of cattle, had formerly all been dedicated to Jehovah (Exod. xiii. 11-13, xxii. 29-30, xxxiv. 18-20). See Ewald's *Antiquities of Israel* (Eng. trans. 1876), Kuenen's *Religion of Israel* (Eng. trans. 1875).

Pass'port is a warrant entitling the person named therein to enter and travel in a foreign country, and to be protected by its laws. For a British subject the best P. is that of the Secretary of State for Foreign Affairs, which costs two shillings, and is good for life. Except in Russia, Turkey, Greece, and Portugal a P. is no longer required, but such a voucher is still occasionally useful in other Continental countries.

Pass'y, a western suburb of Paris, on the N. bank of the Seine, near Auteil, and separated by the fortifications from the Bois de Boulogne. It was an outlying village till 1860, and has now a pop. of about 13,200. There are here celebrated mineral springs.

Pas'ta, Giudit'ta, a great operatic singer, born of a Jewish family near Milan in 1798, was educated under the *maestro da capella* of Como Cathedral, and subsequently at the Conservatorio of Milan. After obtaining a considerable name in Italy, she appeared at the Italian Opera House at Paris in 1823, and during ten successive years was one of the leading operatic favourites in London, Paris, and Vienna, shining particularly in the grander and more tragical of rôles, such as Medea, Norma, and Semiramide. Her voice was a rich and sweet mezzo-soprano of extensive compass, her style and intonation pure, and her expression and gesture in admirable taste. After thirty years of retirement, she died at her villa, Lake Como, April 1, 1865.

Paste, a term loosely applied to substances so diverse that no general definition could be framed to embrace the whole. Properly it indicates substances prepared with water or other liquid till they attain a soft plastic or semi-gelatinous condition, and the fundamental form of P. is the flour P. used as an adhesive material for paper, and by shoemakers, paperhangers, and other artificers. It is made by boiling common flour with water to a perfectly smooth consistence, and it is made of a different degree of consistence according to the purposes to which it is applied. Flour P. may be preserved from moulding by the addition of a minute proportion of carbolic acid or a few drops of any essential oil or camphor; and the addition of a little alum increases at once its adhesive properties and tends to preserve it. Several substances used as food and in confectionery are also, owing to their consistency, called pastes. Thus we have pastry, anchovy and other fish pastes, almond P., and numerous fruit pastes, jujubes, &c.; and in pharmacy a great number of medicated pastes (the *pâtes* of the French) are prepared by mixing gum arabic, sugar, and the requisite medicinal agent into a stiff P. which when dried assumes the form of jujube. Further, numerous other medicated pastes are prepared for external application, and there are depilatory pastes, corn pastes, shaving pastes, tooth pastes, and many others. Polishing P. again embraces a distinct variety of substances used for burnishing and polishing metallic surfaces, and furniture polishes are also sold under the name of P. Further, the term is applied to the material or body of porcelain or pottery ware in contradistinction to glazes and surface colours, and under the name of P. is also indicated the glass or 'strass' used as the basis of imitation precious stones. See GLASS.

Pastille, or **Pastil**, a small cone of odoriferous material prepared for burning to diffuse a pleasing odour in apartments or for the purpose of fumigating. Pastilles are made of a combination of numerous perfumes with gum benzoin, styrax, oil-banum, or other sweet-scented gum resin. Mouth or brentn pastilles—small pills made of a tough consistency—are highly

aromatic. They dissolve slowly in the mouth, leaving a persistent aromatic odour. They are principally used by smokers.

Pas-to, a town of Colombia, S. America, on a fertile plain among the Andes, 8500 feet above the sea, and 150 miles N. E. of Quito. Its inhabitants, 8000 in number, are mostly Indians and mestizoes engaged in agriculture, cattle rearing, and the transit trade with Quito.

Pastor, a genus of *Insectorial* birds, belonging to the Conirostral section of the order, and to the *Sturnina* or starling sub-family. They have a straight bill, the groove in which the nostrils are placed being covered with feathers. The second quill is the longest, and the tarsi are scaled in a transverse fashion. The tail is even. Of this genus the rose-coloured pigeon (*P. roseus*), a rare English species, but common in India, is a good example. Its length is about 8 inches. It has a crest of jet black feathers, and the neck, tail, and wings are also black. The back, breast, and sides are rosy pink. The crest appears to be developed in its third year. The name 'pastor' has been given to the genus because the bird frequents sheepfolds and cattlefields.

Pastoral (in Music), a simple melody of a P. style, usually in 3 time. The term is also applied to music intended to depict P. scenes and incidents.

Pastoral Letter. The first pastoral letters were those in the New Testament addressed to Timothy and Titus, and called Pastoral Epistles, because they abounded with instruction regarding the oversight of the Church and other duties of the Christian ministry, as well as for the churches themselves. The name was afterwards applied to similar letters written by bishops to the clergy and laity under their jurisdiction, either regularly or on special occasions. In the Anglican Church the regular P. L. is superseded by the modern Episcopal 'charge.' In non-Episcopal churches the name is given to an address from a minister to his flock, or from the ministers collectively to the laity of the Church.

Pastoral Poetry is strictly the poetry of shepherd (Lat. *pastor*) life—of those whose daily employment is to tend flocks and herds. Its elements are simple. Milton, referring to the shepherds who watched by night, and sat 'simply chatting in a rustic row' on the Plains of Bethlehem, suggests the range of the speculations and aspirations of pastoral tribes—and thus points out the limits of the subjects properly within the compass of P. P.:—

* Perhaps their loves or else their sheep
Was all that did their silly thoughts so busy keep.'

The oldest representations we have of the poetic character of pastoral life are to be found in the books of the Old Testament, which describe the shepherd life of the patriarchs. But in these the poetry is not the element of first importance. It is there because it belongs to that mode of life, not because the narrative is artistically shaped or moulded to bring it into prominence. Hellas is the land which first gave birth to P. P. in the classic sense of the term. Theocritus (q. v.) is the earliest and the greatest name in this kind of literature. It would be a mistake to suppose that P. P., like pastoral life, belongs to the infancy of a nation. On the contrary, it is often the outcome of a late and languid civilisation, and always paints pictures of a rural life imagined rather than observed. Theocritus flourished at a period (about the middle of the 3d c. B. C.) subsequent to the great age of Hellenic culture, long after the Hellenes had achieved their greatest triumphs in literature and the arts, and indeed well within that period when idyllic simplicity and innocence had completely vanished from the land. Virgil's *Bucolics*, though instinct, like those of Theocritus, with a genuine feeling for the charm and grace, the innocence and sweetness, of country life, were written when Rome was parting with even the last forms of its antique simplicity. The unreality or artificial character of P. P. increased the further the world departed from the classic times. To trace the history of this unreality through the middle ages would be vain. We may here note that on the revival of learning in the 15th and 16th centuries, P. P. reappeared with the other forms of ancient art, sometimes in a dramatic form. Tasso and Guarini among the Italians, Ronsard and Vauquelin among the French, were noted for their skill in

this kind of composition, while in England some of the finest Elizabethan workmanship is shown in this department. Spenser's *Shepherd's Calendar*, Fletcher's *Faithful Shepherdess*, Marlowe's *Passionate Shepherd's Invitation*, with Raleigh's *Reply*, and Browne's *Britannia's Pastorals*, are among the memorabilia of English literature. Gay's *Shepherd's Week* is a delightful and genuine work, but perhaps the best English pastoral in existence, because the one which combines poetic art with the greatest truth to nature, is the *Gentle Shepherd* of Allan Ramsay (q. v.). Amid the hard realities of modern life, P. P. has evaporated, and the pastoral feeling now finds expression only in isolated passages of Wordsworth, Tennyson, and other meditative poets.

Pastoral Staff. See CROSIER.

Pastoral Theology, in a sense, might be regarded as synonymous with practical theology, or the art of applying in the ministry the knowledge acquired in the purely scientific departments of theology; but considered apart, as a special object of study, is that which treats of all the duties and of all the kinds of activity to which the pastor is called. The elements of P. T. thus depend on the conception formed of the spiritual office in the Church. A pastor in the Evangelical Churches is defined as combining in his person all the offices of the priest and prophet of the Old Testament, and of all the different orders of ministry in the primitive Church; and his duties may be divided into the three provinces of worship, teaching—including preaching and catechising—and care of souls. See Vinet's *Theologic Pastorale* (Eng. trans. 2d ed. Edinb. 1855).

Pastry consists of articles of fancy bread, of which 'paste' is the principal ingredient. The paste is prepared by making a soft flexible dough of flour, in which a weight of butter equal to the flour is enveloped, and the whole rolled out to a thin cake. The cake is folded into two and again rolled out, and the alternate folding and rolling are continued till the whole becomes a mass of exceedingly thin alternate layers of flour dough and butter. During the process of baking such a paste, the vapours disengaged from the butter partly break up the doughy material into fine flakes or laminae which absorb the melted butter, and form a rich friable paste with a pleasing appearance and taste. P. so prepared is used with jellies, mince meat, &c., and a modification of it less rich in butter is used for the crust of pies, &c.

Pastures, as denoted by the derivation of the word from Lat. *pasco*, 'to feed,' are fields or tracts of open land, the herbage of which is eaten off as it grows by the farmer's stock. They may be divided into those that are natural, and those that are laid down by the cultivator, and the latter subdivided into permanent, and such as are subject to a rotation of crops or alternate husbandry. The natural P. consist of ground that has been under grass from time immemorial, and include the richest descriptions, as well as the poorest. The best are used for feeding heavy oxen; those inferior are often grazed by dairy stock; whilst the hillsides and downs are usually devoted to sheep. All good P. grow a very mixed herbage, varying according to locality, soil, altitude, exposure, climate, and other circumstances: it is therefore necessary in forming P. to keep in view peculiarities that present themselves in the constitution and surroundings of the land, as likely to affect the growth of certain species or varieties of plants that may be used for sowing.

Common of Pasture, in English law, is the right of feeding one's cattle on the land of another. What are hence called *commonable* beasts are horses, oxen, kine, and sheep. *Not commonable* are goats, hogs, and geese. In Scotland pasture is a known rural Servitude (q. v.), under which the proprietor of the dominant tenement is entitled to pasture a certain number of his cattle on the grass grounds of the servient tenement. In both countries the right may be constituted by grant or by prescription.

Patagonia, the most southerly portion of the mainland of S. America, has a length from 38° to 53° S. lat. of fully 1000 miles, and an estimated breadth of 480 miles. Its total area is about 350,000 sq. miles, whilst its population probably does not exceed 6500. P. is divided from the Argentine Republic on the N. by the Rio Negro, and is bounded on the W. by Chili and the Pacific, on the E. by the Atlantic, and on the S. by the

Strait of Magellan. Its shores are greatly indented, the E. coast forming a number of large bays, of which the principal are the Gulfs of San Matias and St. George, while the W. coast consists of several archipelagoes of islands and a number of peninsulas, all of which are mountainous and densely wooded, much resembling the coast of Norway or that of the S.W. portion of New Zealand. (See CHILOE and CHONOS ARCHIPELAGO.)

P. is traversed throughout its whole length by the great chain of the Cordilleras, which divides it into two districts of widely different character. That on the W. side of the range is a very narrow strip of wooded, mountainous country, with an exceedingly humid climate; while the E. side consists of bare, rolling plains devoid of trees, and with a very dry climate. These plains near the coast are desert wastes, strewn with rocks, seamed by ravines, and bearing only a struggling vegetation of scanty coarse grass, thistle clumps, and incense bushes. The tract between the Chupat and Chico rivers is especially desolate, and the Indians declare it to be impassable. The geological formation of the plains of P. is different from that of the Pampas (q. v.) of the Argentine Republic, consisting as it does of a series of Tertiary formations rising one above the other in terraces as regular as steps, and covered with a shingle bed of porphyry pebbles. Near the base of the Cordilleras the Tertiary formation is overlaid with basalt, and the country is hilly, clothed with grass, and capable of cultivation. On the slopes of the Cordilleras themselves, trees grow thickly, and some of the valleys are surpassingly lovely. Volcanoes are common in the main range, and traces of volcanic action are abundant elsewhere. The principal rivers have all an easterly course, and named from N. to S. they are:—The Rio Negro (q. v.), Chupat, Desire, Chico, and Santa Cruz. They flow in deep gorges and are all exceedingly rapid, but are navigable by vessels of light draught and sufficient steam-power almost to the base of the Andes. In March 1877, Moreno found that the Santa Cruz had risen 63 feet, with a channel in places a mile wide, and a current running 15 miles an hour. He pronounces this river navigable by steamers drawing 12 feet of water. Shallow salt lakes, called *salinas*, are very common in P., but the only large lakes are those of Viedma, Coluguape, Argentine, and San Martin. The first is 30 miles long, with a maximum breadth of 10 miles.

The climate of P., except in the sheltered valleys of the Andes, is exceedingly trying, its leading feature being the prevalence of strong piercing winds, before which in winter no human being can stand on the bleak plains. In the S. snow, sleet, or rain falls almost daily, and Mr. Musters sums up the character of the climate of this region as consisting of 'a hard winter and a bad spring.' Farther N. scarcely any rain falls, but the plains are buried in snow in winter. Notwithstanding the rigours of its climate, however, the animal life of P. is considerable. Independent of herds of wild horses and cattle which roam in the northern districts in the Andean valleys, the fauna includes the guanaco, puma, wild cat, gama (a kind of deer), armadillo, skunk, fox, wolf (*Canis jubatus*), and great numbers of rodents, besides two kinds of ostrich, the condor, three kinds of hawk, an ibis, and (in the N.W.) the flamingo and rose-coloured spoon-bill. The reptiles and insects are few and unimportant, with the exception of a large fly. The fossil remains of P. are numerous and interesting, but little is as yet known regarding them.

The Tehuelches, or Patagonian aborigines, are a tribe of Horse Indians, inhabiting the portion of the country to the E. of the Cordilleras. They are divided into two great sections, inhabiting respectively the N. and S. portions of the country. The members of these two divisions speak the same language and intermarry, but nevertheless preserve their clannish distinctions. Between the Rio Negro and Chupat rivers are the Penck or Pampas Indians, speaking a different language from the Tehuelches. In the N.W. are the Warrior or Manzanero Indians, who resemble the Araucanians, and are more civilised than the other tribes named, keeping sheep and cattle, cultivating maize, and building houses. The stories of ancient travellers regarding the extraordinary stature of the Patagonians have been found to be exaggerations, with some basis of fact. According to Musters, the average height of the men would appear to be about 5 feet 10 inches, and of the women 5 feet 6 inches. Moreno declares, from actual measurement, that 'these people are, without doubt,

the tallest of all the races on the globe.' They are exceedingly muscular, and the development of their arms and chests is especially remarkable. Their complexion is a reddish-brown, and the features good, the eyes being bright and intelligent, the nose usually aquiline and shapely, the teeth superb, and the expression, when not near the settlements, lively and good-humoured. No hair is allowed to grow on the face, and that of the head, which the men wear fully as long as the women, is dressed with much care. The clothing of the men consists of a *charipa*, or under-garment round the loins, over which is worn a large mantle of guanaco skins, the fur of which is worn inside, while the outside is painted, and the garment is thus both warm and waterproof. Skin boots are worn when riding, but the head is generally left uncovered. The women wear a skin mantle similar to that of the men, and beneath it a loose calico or stuff sacque, extending from the shoulders to the ankles. Both sexes smear their faces, and frequently their bodies, with paint, as a preservative against the effects of the dry and cutting winds. The ornaments worn are usually silver or bead necklaces, very large square earrings, and silver spurs or stirrups. The Tehuelches bathe daily in cold water, but in spite of their cleanliness are unable to get rid of vermin. They almost live in the saddle, yet are capable of great pedestrian feats. Their arms consist of guns, revolvers, swords, daggers, and a long heavy lance, used only when on foot. In hunting they use the Lasso (q. v.), *bolas*, and *bola perdida* ('lost ball'). The *bolas* consist of three balls of metal, or of stone covered with leather, connected by long hide thongs, and are thrown either so as to entangle the legs of an animal, and so check its flight, or so as to strike it on the head, and kill or stun it. The *bola perdida* consists of a single ball of similar construction, but with a sharp point, and when once thrown is not picked up again, whence its name. It was the original weapon of the Tehuelches, before the introduction of firearms. Suits of chain armour, or padded skin coats, studded with silver, are still worn in battle to some extent, though going out of use. The *toldos*, or dwellings, of the Tehuelches, are movable huts made of guanaco skins stretched upon stakes. The morals of the race are remarkably pure for savages, and though polygamy exists it is practically confined to the chiefs. The women enjoy social equality with the men, and wife-beating is unknown. Both parents evince a deep and tender affection for their children. The Tehuelches believe in the existence of a good spirit, but their *cultus* consists principally in the exorcism or propitiation of evil demons, the chief of whom is called the Gualichu. Their superstitions in this respect are very strong, and 'doctors,' or 'medicine-men,' consequently exercise great influence among them. Musters estimates the total number of the Tehuelches at only 1500, and as they are decreasing by war, intemperance, and smallpox, they will soon be extinct.

The ownership of P., S. of the Santa Cruz River, is a matter of dispute between Chili and the Argentine Republic, and the latter also claims the rest of the country. There is a Chilean colony at Punta Arenas, in the Strait of Magellan, and there are Argentine settlements at Patagones (formerly called El Carmen), at the mouth of the Rio Negro, and at Santa Cruz. Patagones has a very mixed population of about 2000. On the Chupat river, 40 miles from its mouth, there is a Welsh colony, which had a population of 690 in February 1876. Its inhabitants have at various times narrowly escaped starvation, but there is now regular communication with Buenos Ayres. In 1875 the Chupat settlement exported to that city wheat, skins, and ostrich feathers to the value of £7306. The site of the colony is fertile but almost rainless, rendering artificial irrigation indispensable. The river is navigable, but has a shallow bar entrance. In 1875 a Scotch colony, consisting of 140 families, was planted at Port Desire, under the auspices of the Argentine Government.

The first European who visited P. was Magellan, who landed at Port St. Julian (49° 30' S. lat.) in 1520, and explored the coast as far as Santa Cruz, in 50° S. Two months after landing at the former place they were visited by some of the natives, who wore rough boots made of hide. These boots left very large foot-prints on the sand, on which account the Spaniards nicknamed their wearers *Patagones*, or 'large feet,' whence the name P. Of subsequent explorers, the chief were:—Sir Francis Drake in 1578; Sarmiento in 1579 and 1581; Cavendish in 1586; Narborough in 1669; Faulkner about 1750; Byron and Wallis in 1760; the brothers Viedma in 1780, and Fitzroy and Darwin in 1834. In 1869–70 Commander Musters, R.N.,

travelled throughout the entire length of the country, and has given the best account as yet published of its character and inhabitants. The latest explorers have been Lieutenant Fulberg in 1873 and Señor Moreno in 1877, the former of whom was in the service of the Argentine government. See *At Home with the Patagonians*, by G. C. Musters (Lond. 1871); *La P. y las Tierras Australes*, by Vicente G. Quesada (Buenos Ayres, 1875); *Report to the Minister of Foreign Affairs at Buenos Ayres* by F. P. Moreno, published in the *Geographical Magazine* for 1877.

Patapsco, a river of Maryland, U.S., has a S. and S.-E. course of eighty miles, and enters Chesapeake Bay by a fine estuary, on which stands Baltimore. In its upper course it is very rapid, affording excellent water-power.

Patchouli is a famed scent procured from *Pogostemon Patchouli*, a perennial herb of the natural order *Labiata*, native of the mountain districts of India and the Malay Peninsula. It grows to the height of two feet, with a habit something like that of mint, having broad oval leaves of some four inches in length; and from the stem tops, with their leaves and dense spikes of small purplish-white flowers, the perfume is derived by extracting the volatile they contain. The dry leaves in a powdered state are made up into small packets, and kept amongst clothes as a preservative against moths: they are also used for scenting certain tobaccos. To some people the odour of P. is disagreeable, but in the East, under the name of poucha-pot, and now in Europe, since its introduction in 1844, it is an established popular perfume. Prior to its importation as an article of commerce, it was a recognised test of the Cashmere shawls—the genuine article being always scented with P. The genus *Pogostemon* contains other species—all natives of tropical Asia—but they do not possess any qualifications of interest.

Patée Cross. See MALTESE CROSS.

Patella, a genus of Gasteropodous Mollusca, represented by the common Limpet (q. v.) (*P. vulgata*) and by allied species. It forms the type of a family (*Patellidae*) distinguished by the conical form of the shell, which is a simple cone, and which does not exhibit the spiral arrangement characteristic of such Gasteropodous shells as those of the whelks. The remaining characters of the family and genus are these; the apex of the shell is turned forward, the 'foot' being as large as the mantle; the gills are in the form of plumes lodged in the mantle cavity, or (as in limpets) as a series of delicate processes surrounding the body.

Patella, the 'knee cap' or 'knee pan,' a small bone found in man in front of the knee-joint, and destined for the protection of that articulation. It may be absent in some quadrupeds (e.g., wombat), and it is very small in bats and seals. It is large in some birds (e.g., grebe), and it is wanting in frogs and tortoises. The P. exemplifies what is known to anatomists as a *sesamoid bone*—that is, it is not developed from cartilage as an ordinary bone of the skeleton, but is found within a tendon—that of the *quadriceps extensor muscle* of the thigh. In man it is flat and triangular in shape. Its anterior surface is convex and rough, its under surface smooth and oval. The *ligamentum patellæ* is attached to its apex or lower margin. In structure, the P. is composed of cancellated bony tissue. It is developed from a single centre, and makes its appearance about the third year of life.

Injuries and Diseases of the P.—The P. may be fractured in two main forms. The ordinary form is transverse, and is commonly caused by the action of the great extensor muscle, the bone being snapped before the patient falls to the ground; but it sometimes occurs that a transverse fracture is produced by direct violence. Fracture of the P. is accompanied by laceration of the fibrous tissues covering the bone; and, in proportion to the laceration, the upper fragment is liable to be separated from the lower by the action of the quadriceps extensor at the moment of the accident. After the accident, the patient is almost or entirely unable to extend the limb; a depression is felt between the two fragments, and there may be considerable swelling and effusion into the knee. The foot and leg should be placed on a straight splint properly padded, bringing down the upper fragment of the P. as near the lower as possible. This is often difficult, owing to the persistence of effusion in the joint; but the parts may be brought into juxtaposition by the use of

Malgaigne's hooks, which, however, should not be applied till all active effusion has subsided. The upper fragment may sometimes be drawn downwards by the action of bandages or strapping applied to the skin over its upper end. The union is generally ligamentous; and, as a general rule, the patient ought to be kept in bed for six weeks, and for six weeks longer the limb should be kept in a splint which will not allow of any bending. *Compound fracture of the P.* is a very severe accident, usually accompanied by other injuries to the articulation, and requiring amputation of the limb.

Pat'en (Lat. *patina*, a dish) is the plate used for holding the bread in the sacrament of the Eucharist.

Patent Laws. The two main conditions of a patent are, first, that the invention on account of which it is granted be useful and new, and, secondly, that the patentee furnish a specification of it sufficiently clear to enable the public to have the benefit of it as fully and as cheaply at the end of the period of the patent as the patentee has during its currency. Hence, if the description, plan, or model of any new invention be unintelligible to those engaged in the business to which it relates, the patent cannot be maintained. There of course must ever remain the difficulties of defining what is a new invention, and of whether or not an imitation is an infringement. By 5 and 6 Will. IV. c. 83, amended by 2 and 3 Vict. c. 67, an attempt was made to obviate some of the defects of the P. L., and better to secure the rights of inventors and discoverers. Formerly, an inadvertent claim of novelty regarding any part of an invention, however trivial a part, if shown to be incorrect, was fatal to the patent. This defect has been obviated, and a patentee who finds that he has been anticipated in any portion of his invention may now disclaim that portion, and retain his exclusive privilege in the remainder. The Act gives power to the Crown, on the recommendation of the Privy Council, to extend the term of a patent from fourteen to twenty-one years. In 1852 the P. L. were further amended, and the facilities for obtaining letters patent for inventions extended. Under the Act, a commission is constituted, and empowered to make regulations, which are to be laid before Parliament. The commission is required to report to Parliament annually. Under the Act, every petition for the grant of letters patent, and the declaration required to accompany it, must be left at the office of the commissioners, and along with these a statement in writing, signed by or on behalf of the applicant, describing the nature of the invention. The application is then to be referred to one of the law officers of the Crown, who may call a scientific person to his assistance, at the expense of the applicant. The law officer may then give a certificate of allowance, and thereupon provisional protection is extended to the invention for six months. The letters patent must be taken out before expiration of the six months, or the inventor loses his right to them. They are valid over the United Kingdom, Channel Islands, and the Isle of Man; but fees must be paid for recording the patent in the Court of Chancery (q. v.) in Scotland. The following are the principal stamp duties now payable in place of the sums under the Act of 1852:—Petition, certificate of notice to proceed, warrant for letters patent, sealing of letters patent, specification, application for disclaimer—£5 each; certificate of record of notice of objections and caveat against disclaimer—£2 each. At the end of the third year of the patent £50 must be paid, and £100 at the end of the seventh. Besides these expenses there will be others incurred to the law officers of the Crown, in the event of opposition, both by the applicant and opponent. 22 Vict. c. 13 provides for inventions regarding *instruments or munitions of war*, which may be assigned to the Secretary of State for War, who will certify to the commissioners for patents that such inventions will be kept secret. A Royal Commission on the P. L. made its report in 1864, and there have been later committees of inquiry, but the evidence given and the opinions expressed upon it are so conflicting, that to base any view on authority is clearly impossible. The general opinion seems to be that some reform is required, but what the reform ought to be is the subject of endless divergence. Some advocate total abolition of patent rights.

Paterculus, C. Velleius, a Roman historian, born about 19 B.C., served in the army under Tiberius, by whom he was made prætor in 14 A.D., and is supposed to have died shortly after 30 A.D. The work by which he is known bears the title C.

Vellei Paterni Historia Romana ad M. Vinicium Cos Libri II, and is a compendium of the chief events in universal history from the fall of Troy till A.D. 30. The first printed edition was published at Basel in 1520 from the only manuscript of the work then extant, in which the first seven and a half chapters were wanting, and which has since been lost. The best editions are those of Rhunken (Leyd, 1789), and Orelli (Leips. 1835).

Pater Noster (Lat. 'our father'), the first two words of the Lord's Prayer, are sometimes used as a name for the whole prayer. In the primitive Church the use of this prayer was only permitted to believers; the Catechumens (q. v.) were not permitted to say 'our father' till they had first made themselves sons by regeneration in the water of baptism; from which it received the name of 'the prayer of the faithful.' Hence it was learned immediately before baptism, and used at baptism as well as at the Eucharist, at morning and evening services in churches, and in private devotions, from which it received the name of 'the daily prayer.' In short it was often used as the conclusion of all prayers, and in the Apostolic Constitutions (q. v.) was directed to be used three times a day, probably in honour of the Trinity. It was in this way that the P. N. came to be the foundation of the Rosary (q. v.).

Paterson, a city of New Jersey, U.S., on the Passaic river, which here forms a fall 100 feet high, affording excellent water-power, 13 miles N. of Newark, and 16 N.W. of New York by rail. It has 35 churches, 2 orphan asylums, 2 daily and 3 weekly newspapers. Silk is extensively manufactured, there being twenty-five firms engaged in that industry; and on this account P. has been called the 'Lyons of America.' The chief other manufactures are machinery, paper, carpets, and cotton and linen goods. Pop. (1870) 33,579.

Paterson, William, was born in the parish of Tinwald, Dumfriesshire, in 1658, and is stated to have embraced a missionary life in the W. Indies, from which he deviated to that of a buccaneer. By 1688, however, he is known in honourable connection with commerce, the banking schemes which he submitted to the merchants of London having issued in the projection of the Bank of England. It is in his connection with the Darien Scheme (q. v.) that he lives as a figure of historical importance. By dint of natural eloquence and the repetition of an argument which promised to make Scotland, if her parliament sanctioned the establishment of a trading company at Darien, 'the general storehouse for tobacco, sugar, cotton, hides, and timber,' P. pushed the scheme into execution. It was a ruinous failure, and he came back to Scotland in a condition of insanity. He was afterwards returned to the first united Parliament for the Dumfries burghs, and in 1715 the sum of £18,241 was voted as indemnity for his loss in the disastrous transaction. 'There is not,' says Lord Macaulay, 'the least reason to believe that he was dishonest. Indeed, he would have found more difficulty in deceiving others had he not begun by deceiving himself. His faith in his own schemes was strong even to martyrdom, and the eloquence with which he illustrated and defended them had all the charm of sincerity and enthusiasm.' He died 22d January 1719. See Bannister's *W. P.* (1858), and Pagan's *Birthplace of W. P.* (1865).

Pathán, the same as Afghan, a name commonly used throughout India for men of Afghan descent who have settled in that country, especially for the Kohullas (q. v.), or for those who have entered the British military service. According to the general census, 1868-72, they number 1,841,693 throughout British India, being most numerous in the N.W. Provinces, the Punjab, and Oude.

Pathological or Morbid Anatomy is that department of medical science which treats of the changes produced by disease in the solids and fluids of the body, and is a record of facts from which it is possible to ascertain the conditions under which morbid changes or new formations in the body have taken place. The progress of P. A. is therefore, in great measure, a record of the history of medicine; but ordinary dissections alone have long since ceased to furnish us with facts before unknown. The great advances made in P. A. within recent years have been in consequence of greatly increased physical aids to the senses; and organic chemistry, the microscope, the ophthalmoscope, the clinical thermometer, the graphic method, and such like instruments, are continually opening up new fields of in-

quiry. The province of P. A. is to detect the changes which have taken place during the course of diseases in the structure of the tissues and organs of the body; and to demonstrate the exact seat of local alterations established during the progress of disease. P. A. is merely a section of pathology, contributing to practical medicine the solid material from which to construct a basement without having the power to erect a perfect edifice, as Professor Vogel has well remarked. See Vogel's *Pathological Anatomy of the Human Body*, Jones and Sieveking's *Manual of Pathological Anatomy*.

Pathology (Gr. *pathos*, 'suffering,' hence 'disease,' and *logos*, a 'discourse') treats of the origin, development, growth, and decay of new products or formations which are the elementary constituents of structural or organic lesions. As a science it is of modern origin. The investigation and elucidation of the cause, nature, and course of those changes which are detected and demonstrated by the morbid anatomist constitute the main objects of the science of P. The difference between pathological anatomy and P. is put by Professor Aitken of Netley thus—'The morbid anatomist finds a lesion or change for what ought to be the natural structure, appearance, or condition of a part. The pathologist seeks to connect such lesions with signs and symptoms during life, that the practical physician may suggest a remedy to the disease, and that the nosologist may give it a name, distinguishing characters, and a place in his classification.'

Patmos (mod. Patino and Patmosa) is a bare, rocky island in the Ægean Sea, about 28 miles in circumference, which under the Roman emperors was used as a place of banishment, and which now contains about 4000 to 5000 inhabitants. About halfway up the hill on which the only town in the island is built is shown a natural grotto in the rock, in which tradition affirms St. John wrote the Apocalypse (cf. i. 9). High over all stands the celebrated monastery of 'John the Divine,' dating from the 12th c., and now occupied by 50 monks and containing a considerable library.

Patna, the chief town of the district and division of the same name in Bengal, British India, and the commercial capital of Behar, on the right or S. bank of the Ganges, opposite the confluence of the Gunduck, 331 miles by rail N.W. of Calcutta, and 623 miles S.E. of Delhi. Pop. (1872) 158,900, including 38,729 Mohammedans. P. is the sixth largest city in India. The military cantonment of Dinapore, 6 miles to the W., has an additional pop. of 42,084. The seat of the civil administration is called Bankipore, a western suburb; the native town is locally known as Azimabad. P. is undoubtedly an ancient city. It has been identified with Patahputra, the capital of the Emperor Sandracottus, visited by the Greek historian Megasthenes about 300 B.C., and by him called Palibothra. Shortly afterwards it was the seat of a Buddhist council, assembled by the great Asoka. There are no ancient ruins. The chief buildings are the *Gola* or storehouse, built in 1786 as a protection against famine, which was never made use of till the famine of 1874, the Government opium-stores, the Roman Catholic church, and several mosques. P. College, founded in 1862 in connection with the Calcutta University, was attended in 1874 by 92 pupils, at a cost to Government of £3286. The Temple School of Medicine was opened in 1874. In modern history P. is noted for the massacre of the British prisoners by the Nawaub Meer Cossim in 1763, for the Mutiny at Dinapore in 1857, when the Sepoys went off securely into Shalabad, and for the trial of the Wahaabee rebels in 1864. The Mohammedan ceremony of the Mohurram is annually celebrated with great pomp. The trade of P. is very great both by river and rail. It is the great emporium on the Ganges between Cawnpore and Calcutta, where the agricultural produce of the surrounding country is received by water, to be despatched by rail to the seaboard. In 1876-77 the registered imports were valued at £4,161,000, including cotton goods £1,217,000, salt £390,000, sugar £274,000, and timber £98,000. The exports were valued at £3,090,000, including indigo £789,000, oil-seeds £532,000, hides £185,000, saltpetre £156,000, wheat £82,000, rice £74,000, and other food-grains £96,000. The manufactures are the Government monopoly of opium, cotton and silk weaving, gold and silver lace, leather, glass, rose-water, &c. Spirits are distilled annually to the amount of 1,000,000 gallons. The district of P., which is bordered by the Ganges and the Soane, has an area of 2101 sq. miles; pop. (1872) 1,559,638. The soil is fertile; but the

'P. rice' of commerce is to a great extent a re-export. Besides rice, the crops are gram, barley, wheat, Indian-corn, and oil-seeds. The towns are Behar, Futwa, Barh, and Mokameh. See General Cunningham's *Ancient Geography of India* (vol. i. Lond. 1871).

Patois, a French word of unknown origin, is used to denote a local dialect when it has either ceased to have, or has never had a *literature*, but exists only in the everyday speech of rustics. It may have its quaint and naive peculiarities, but it has neither eloquence nor dignity. Thus, the English of the Somerset peasants is strictly a P., while the English of the Lowland Scotch peasants is not, because it continues to be a vehicle of literature. When it ceases to be that, it too will become a P. See Littré, *Histoire de la Langue Française* (2 vols. 1862), and Cocheris, *Origine et Formation de la Langue Française* (1872).

Pa'ton, Sir Joseph Noel, a distinguished Scottish artist, born at Dunfermline in 1823, was engaged for sometime as a pattern designer, and afterwards studied at the Royal Scottish Academy and the Royal Academy of London. His undoubted power as a draughtsman manifested itself at an early date, and his 'Spirit of Religion' (cartoon) bore off a premium of £200 at the Westminster Hall competition (1845). His 'Quarrel' and 'Reconciliation' of Oberon and Titania, are splendid illustrations in colour of well-known incidents in *Milsummer Night's Dream*, and are the property of the Royal Scottish Academy. Among his other works are the 'Dead Lady' (1854), 'Pursuit of Pleasure' (1855), 'In Memoriam' (1857), 'The Dowie Dens of Yarrow' (1860), 'The Temptation' (1876), and 'Life or Death' (1878). Probably his most truly artistic productions are his outline drawings in illustration of the works of Shakespeare, Shelley, Coleridge, Aytoun, &c. He was appointed Queen's Limner for Scotland in 1865, and was knighted in 1867. He is the author of a volume of graceful verse called *Poems by a Painter* (1861).—**Waller H. P.**, younger brother of the preceding, is well known for his careful and picturesque, though somewhat mannered representations of Scottish scenery. He shows great delicacy of manipulation, but is scarcely true in colour, and the effect though brilliant is somewhat monotonous. Among his best-known landscapes are 'Entrance to Glencoe,' 'Bass Rock from Carty Bay,' 'Evening on Loch Striven,' and 'In Lochaber,' all of which were exhibited in the Royal Scottish Academy in 1877, and are favourable specimens of his style.

Pat'ras (*Patras*; Turk. *Baliabadra*), a fortified seaport in the W. of Greece, and capital of the nomarchy of Achaia and Elis, on a gulf of the same name, near the entrance to that of Corinth. The most important trading town of Greece, it is a beautiful city, with regular streets and extensive arcades, and has a mole, which was being lengthened (1877) by French engineers at a cost of £65,000. A strong citadel stands on the old Acropolis. P. has various slight industries, including the manufacture of cotton-twist and soap, and exports currants (in 1876 70,000 tons, 53,556 to Great Britain) tobacco, cotton, olive oil, figs, cocoons, &c. In 1876 exports by British vessels alone amounted to £818,100, and the imports to £226,150. Of the 389 vessels of 138,477 tons that entered the port in 1873, 156 were Greek, 142 English, and 31 Italian. The imports are mainly cottons, iron, coals, coffee, sugar, codfish, and petroleum. Recently the cultivation of currants has been greatly promoted by the sale of government lands in all the plains of the Peloponnesus. There are gas-works at P., but the town is still lit by petroleum lamps. Pop. (1870) 16,641. P., the ancient *Patra*, is the only one of the twelve Achaean cities still existing. In A.D. 347, there was an archbishop of P. at the Council of Sardica. The city was sold to the Venetians in 1408, was taken by the Turks in 1446, recovered by the Venetians in 1533, but shortly afterwards again taken by the Turks, who held it till the revolution of 1821-27.

Patria Potes'tas is a term used to denote the power of Roman citizens over their children. By the laws of the twelve tables the father had power of life and death over his offspring. He could expose them when infants, and their legitimacy depended upon his acceptance of them. He could sell or resign them, instead of paying the damage which he had incurred through their fault. They could neither contract marriage nor do anything else of importance without his consent. But when he did permit his daughter's marriage, his paternal rights as to her

were destroyed, and she became equally with her own daughters the *filia familias* of her husband. A son could acquire no property but with his father's consent; and even when that was granted, his acquisitions were called *peculium*, the term applied to the portion of a slave. The P. P. yielded to the son's official dignity, but revived when that ceased, extending even over grandchildren and great-grandchildren, and ceasing only when extinguished by natural or civil death, or by the ceremony of emancipation. In no modern nation of Europe has the law given anything like the same scope to paternal power. Somewhat greater authority is given to the father in France than in England. In neither country does it extend beyond majority. See PARENT AND CHILD, AGE.

Pa'triarch (Gr. *patriarchēs*, the father or chief of a race, or 'chief-father') is the name given to the common ancestor from whom clans or tribes of people have supposed themselves to be descended, in order to account for the closeness of their connection; e.g., the different *Mac*s in the Scottish Highlands, or the *Bani*, *Bani*, among the Arabs, both meaning sons of so and so. National historians, gazing back into the dim ages of a remote antiquity, are fond of reducing the events of primitive times to an unnatural and unhistorical symmetry, by representing tribes or groups of tribes as individuals or families. Thus the Greeks or Hellenes traced back their origin to a certain Hellen, the son of Deucalion and Pyrrha, whose sons Dorus and Æolus, and his grandsons Achæus and Ion, were the patriarchs of the four Greek tribes.

In Jewish history, the name of P. is applied to the ten descendants of Adam down to Noah (Gen. v.), who are called the Antediluvian patriarchs; to Noah's descendants down to Terah (Gen. xi.); and particularly to the immediate progenitors of the Israelites, Abraham, Isaac, Jacob, and Jacob's twelve sons, the last of whom are specially spoken of as the twelve patriarchs (*cf.* Acts vii. 8, Heb. vii. 4). The title of P. is even in a way applied by St. Paul to the Almighty, as the father of the whole human race (Eph. iii. 14, 15). After the destruction of Jerusalem the name was applied to two governors or heads of the Jews dispersed throughout the Roman and Persian Empires, one of whom had his residence at Tiberias, the other at Babylon.

In the hierarchy of the Christian Church, a P. was a dignitary ranking next to the Pope. In the course of the development of the hierarchy it came to be recognised that the bishop of the chief city of a region, or Metropolitan (*q. v.*), ranked above an ordinary bishop. Then, on the same principle, the bishop of the chief town of the larger provinces of the Roman Empire was elevated above the other metropolitans. Such were the Bishops of Rome, Constantinople, Alexandria, and Antioch, who received the title of Exarch, Archbishop (which was afterwards equivalent to metropolitan, and, shortly before the Council of Chalcedon (451), that of P., which in the 4th c. had been applied to bishops generally. Ephesus and Caesarea had the honour for a time of ranking as patriarchates, but had to fall back and make way for Jerusalem. In the West the bishops of Carthage, Justiniana, Prima, Aquileia, and Canterbury held the rank of P., which in fact was simply that of archbishop, with an accession of power and jurisdiction. See Bingham's *Antiquities* (2d ed. 1726), Morin's *De Patr. Origine* (1686).

Patriar'chal Cross, in Heraldry, a cross formed by an upright shaft crossed by two horizontal bars, of which the upper is the shorter.

Patri'cians (Lat. 'father's children') under the early kings were the original burgesses of Rome (the *populus Romanus*), and were so called because all of illegal or illegitimate birth were excluded from their community, and in the eye of the law were regarded as having no fathers (*patres*). The P. were divided into *gentes* (see GENTES), and these again into *familia*, each of which had its slave and *clientela*, composed of freedmen and foreign refugees. With the rise of a free *plebs* under Ancus Marcius, and its investiture with political rights by Servius Tullius, the P. became an aristocracy of birth, divided into the *patres majorum gentium* (the immemorial nobility) and the *patres minorum gentium* (the immigrant Ramnes, Tities, and Luceres). In the struggle that ensued the great magistracies were one by one thrown open to the plebeians, intermarriage was legalised, the powers of the *Comitia Curiata* were transferred to the

Comitia Centuriata, and in the 3d c. B.C. we find patrician and plebeian standing on an almost perfect political equality, the only exclusive offices retained by the patriciate being those of flamen and interrex (see PLEBEIANS and NOBILITY). Under the emperors the only distinguishing badge of a patrician was a peculiar kind of shoes (*mullei*), tied with four strings, and adorned with a *fibula*. Since the reign of Constantine *patricius* was a personal title, arbitrarily conferred, as well on Roman citizens as on foreign princes—Odoacer, for instance. Pope Stephen IV. granted the title to Pippin, as protector of Rome and the Holy See (754); and it was borne by Karl the Great up to his coronation as emperor. See vol. i. of Mommsen's *Römische Geschichte*, and Freeman's *Comparative Politics* (Lond. 1873).

Patrick, St., the Apostle of Ireland, was born about 387, of Christian parents, at Bonavem Tabernie, a village identified by tradition with Kilpatrick in Dumbartonshire, but of which we only know for certain that it was situated in a part of the Roman province in Britain that was exposed to the incursions of the Scots. He was already ordained deacon when in his sixteenth year he was carried captive to Ireland, and there for six years employed in tending sheep. Restored to his native country by escape in a pagan vessel, he was led by a divine call (*circa* 414) to form the design of evangelising the land of his captivity. Accordingly, having taken priest's orders, he sailed for Ireland, where for many years he laboured with small success. In his forty-sixth year he was consecrated bishop, and himself ordained many clerics, who, according to the Catalogue of the Saints, were 'all bishops, famous and holy, 350 in number, and founders of churches.' He probably died in 458, and his festival falls on March 17th. The scanty incidents in the life of the historic St. Patrick are gathered from his *Epistola ad Caroticum* and the *Confessio*, written shortly before his death, rude Latin documents, which Skene accepts as 'undoubtedly genuine.' In these we meet with no mention of the earlier mission of Palladius, or of the metropolitan jurisdiction of the church of Armagh; nor, though St. P. speaks of the multitudes converted, does he imply that Ireland as a nation adopted Christianity, a circumstance which tallies with our knowledge that no Christian monarch ruled in Tara till 513. Of legendary memoirs of St. P. there is a continuous series from the 7th to the 12th c., the oldest of them being the *Annotations* of Bishop Tirechan. See the Lives of him by J. H. Todd (Dubl. 1863) and Miss Cusack (Kinnare, 1877), and vol. ii. of Skene's *Celtic Scotland* (Edinb. 1877).

Patrick, Order of St., an Irish order of knighthood, instituted by George III. in 1783, to include fifteen knights, under the sovereign, a prince of the blood royal, and the Lord-Lieutenant of Ireland, the latter of whom should be *ex-officio* 'grand master' of the order. In 1833 the number of knights was extended to thirty-three.

Patropassians (Lat. *pater*, 'father,' and *passus*, 'suffered'), the name given to an obscure sect of Christians who appear to have originated in the 2d c. They were in some sense anti-Trinitarians; at least, they are said to have held that whatever is ascribed to any of the Three Persons of the Godhead in Scripture is really true only of the 'One Principle.' Hence their proper name 'Monarchians,' and hence also their nickname of P., by which it was sought to fasten upon them the notion that when Jesus suffered on the cross, it was also the Father that was crucified.

Patroclus, the comrade of Achilles (q. v.), whom he followed to the siege of Troy. There, clad in Achilles' armour, he met his death at the hands of Hector and Euphorbus. Achilles avenged his fall, consumed his body on a funeral pyre, and was afterwards buried under the same mound with him.

Patrol, (1) a march made at night-time through the streets of a garrison town by a small body of soldiers commanded by a subaltern or non-commissioned officer, to insure order and apprehend suspicious persons or truant soldiers; (2) detachments of soldiers acting as watchmen in besieged fortresses or as communicators with outposts.

Patronage, Ecclesiastical. As he who erected a temple to any pagan god had the right of designating the priests who should officiate in it, so, when Christianity was established as the state religion of the Roman Empire, whoever built a church and

made provision by endowment for the support of its clergy acquired, for himself and his heirs, the right of appointing those clergy, subject, however, to their examination and approval by the bishop of the diocese. Bishops founding a church in the diocese of another bishop had this right by a decree of the first Council of Orange (Arausio), 441, repeated in the second Council of Arles (452), but by laws of Justinian (541 and 555), and a decree of the ninth Council of Toledo (655), it was granted to all founders. This came into operation especially when dioceses were divided into parishes, and was doubtless intended as an inducement to landholders to build churches on their property. As regards the bishops, by the laws of Justinian it was enacted that they be elected by the clergy and the chief men of a diocese. In the old Roman Empire the emperor had a voice in the appointment of bishops in the most important cities. The princes of the new Roman Empire of the Franks, however, thought that they were entitled to as much in the case of all bishops, to whom such large revenues and important political privileges were intrusted. The clergy, who sought to obtain bishoprics through the influence of the princes, helped to confirm them in this belief. Thus the ancient practice fell entirely into disuse, and the power of the princes grew into the prerogative of nominating the bishop, whom the clergy had simply to accept. The right of P. granted to laymen was intended as a guarantee that the endowments they conferred on the church would not be abused by the clergy, but, on the other hand, the right itself was liable to be greatly abused. The princes bestowed the bishoprics arbitrarily on their favourites or those who made them tempting gifts, or sold them openly to the highest bidder. Hence, of course, it often happened that unsuitable and unworthy persons were nominated. A similar course was followed by inferior patrons in disposing of parish offices, whilst the latter also were apt to regard the clergy as their retainers, and to seek to make them independent of the bishops. Full proof of the prevalence of these abuses is found in the laws passed by councils of the Church, especially between the middle of the 6th c. and the end of the 9th c., against the laity recommending unsuitable men for the priestly office for the sake of gain. An ordinance of the fifth Council of Paris (615) re-enacting free ecclesiastical elections was confirmed by King Hlothar II., and Karl the Great also restored the theory, but in practice it was not always acted upon. By a decree of the third Council of Valence (855) the share of the monarch in episcopal elections took the form of granting permission on request to the clergy and the community of a diocese to make a canonical election. The asking of this permission was intended by the Church to be a mere formality, but when there was a desire on the part of the monarch to encroach, and no one bold enough to withstand him, he had little difficulty in making more of his right than was intended. Hence the right of investiture of bishops (*i.e.*, by the presentation of a staff and ring), which the monarchs claimed, was continually abused as before; the benefices were bestowed on their favourites, or made a matter of traffic. The bishops who obtained their benefices by simony indemnified themselves by the sale of the inferior benefices in their gift. And the worst offenders of all were the Popes. The mischief reached its height in the 11th and 12th centuries. Boniface IX., who was raised to the Papedom by simony when a boy of twelve (1033), made a rule 'that none should obtain the more important ecclesiastical offices without first advancing a sum of money equal to the income of the first year, the so-called *annates*;' and notwithstanding the attempted reform of Gregory VII., in the beginning of the 15th c. the Roman Curia had the P. of nearly all the higher benefices in the Church. But in the 15th c. these claims of the Pope began to be vigorously opposed by the various European princes, and one after another wrested from him the P. of the benefices within their dominions. This was most thoroughly done in England. Edward III. made a beginning, and already under Henry VII. the undisputed right of nominating to all the bishoprics belonged to the sovereign; and thus it has remained.

The Church of Scotland since the Reformation has always been peculiarly jealous of any interference on the part of the state, and the rights of lay patrons have always been kept as far as possible at a minimum. By an Act of Parliament passed in 1567 a patron had no further power than simply recommending a candidate. According to the First Book of Discipline (q. v.) the right belonged to every congregation of choosing their own minister; and the Second Book of Discipline (1578) condemned lay P. as an evil which had sprung from the Pope and the corrup-

tion of the canon laws. This was all changed by the Parliament of 1534, which abolished Presbyterianism, but when the 'Black Acts' of that year were repealed in 1592, P. seems to have been restored to the same position in which it was placed in 1567. By an Act passed in 1690 the Act of 1592 was re-enacted, with an interpretation, however, which virtually superseded the patrons. In 1711 the famous Act of Queen Anne was passed, by which the rights of patrons were restored. The question now slumbered for a century, but the opposition to P. again attained a white heat in 1834, when the Veto Act was passed by the General Assembly, according to which the veto of the majority of a congregation was a sufficient ground for the rejection of a patron's nominee. P., however, still remained a burning question, till it became the occasion (1843) of the Disruption which gave rise to the Free Church (q. v.). In 1874 it was abolished by Act of Parliament, and the right of electing a minister was vested in congregations. See Bingham's *Antiquities* &c. (2d ed. 1726), Stillington's *Orig. Brit.* (1685), Neander's *Geschichte d. Christl. Rel. u. Kirche* (Eng. trans. 1858), Ranke's *History of the Popes* (Eng. trans. 1847), *Autobiog. and Diary of James Melville* (Pitcairn ed. Edin. 1842).

Patronymics (Gr. *patēr*, 'father,' and *onoma*, 'name'), names derived from those of parents or ancestors, are common amongst all Aryan and Semitic races. They may be simple genitives, as Pauli, William's; derivatives, as Atrides, Briseis; or formed by the prefix or affix of a word signifying 'son,' as Heb. *Barabbas* and *Benhadad*, Gael. *Macdonald* and *O'Brian*, Cymr. *Ap Richard*, Norman *Fitz Urse*, Eng. *Johnson*. Many of our surnames were originally P., disguised, it may be, by the wear of time; e.g., Evans, Dixon, Price (Ap Rhys), Powell (Ap Hoel), Pugh (Ap Hugh), Bevan (Ap Evan), &c.

Pattens (Fr. *patin*, 'a clog,' 'a high-heeled shoe'), a name applied so early as the 14th c. to wooden shoes, and used in the 17th and 18th centuries to denote the sandals or shoes of wood, having iron rings on the soles, worn by ladies during wet weather. These are still common in country parts of England.

Patteson, John Coleridge, D.D., born in London, April 1, 1827, passed from Eton to Balliol College, Oxford, gained a Merton fellowship (1850), and was ordained to the curacy of Alplington (1852). In 1854 he accompanied Bishop Selwyn to New Zealand, where he laboured as a missionary till 1861, when he was consecrated Bishop of Melanesia. The next ten years of his life were spent in cruising among the islands that formed his diocese, in efforts for their improvement, and above all in striving to check the kidnapping of natives to supply the Queensland labour market. This infamous traffic caused his death, for landing in Santa Cruz, he was murdered by the infuriated natives, September 20, 1871. See Miss Yonge's *Life of Bishop P.* (2 vols. Lond. 1874).

Patti, Adeline Maria Clorinda, one of the most gifted of operatic singers, was born in Madrid, March 19, 1843. She received her training under her brother-in-law, Maurice Strakosch, and sang in public at the age of eight in New York. In 1861 she obtained an engagement at the Royal Italian Opera, Covent Garden, where she made her first appearance as *Anima* in *La Sonnambula* on 14th May 1861, and where she still appears regularly during the London season. The brilliant success she then achieved has since been followed by magnificent triumphs in all the leading capitals of Europe. Her youthful and charming appearance, and arch, coquettish manner was admirably suited for such rôles as Zerlina in *Fra Diavola*, Rosina in the *Il Barbiere di Siviglia*, and Norina in *Don Pasquale*, and it was in the lighter operas that she earned her earliest laurels. Of late years, while her fine and pure soprano voice has increased in mellowness and richness of tone, she has assumed with success the highest impersonations on the lyric stage. As Juliet in *Romeo e Giulietta*, and Caterina in *L'Etoile du Nord*, she has never had a rival. She is as popular in the concert-room as in the theatre. The fact that on the Handel Festival of 1877 at the Crystal Palace the largest audience for the first time assembled on the selection day was undoubtedly due to her appearance. As much as £400 is frequently paid her for a single performance. She married the Marquis de Caux in 1868, from whom she obtained a judicial separation in 1877.—**Carlotta P.**, sister of the preceding, born in 1840, is a favourite concert-singer. She has a soprano voice of extra-

ordinary height (extending to G sharp in alto), and of great flexibility.

Pau, the chief town of the department of Basses-Pyrénées, France, on the river Gave-de-P., a tributary of the Adour, 67 miles E.S.E. of Bayonne by rail. It is a well-built town on the edge of a plateau overlooking the beautiful valley of the Gave, and its mild and healthy climate attracts many invalids. The finest squares are La Comédie and La Place Royale, the latter with a bronze statue of Henri IV. of France. The most striking building is the Castle, said to have been founded by Gaston de Foix in 1363, in which Henri IV. was born, and which was the prison of Abd-el-Kadr in 1848. Among the other conspicuous buildings of P. are the palace of justice, the museum, and the new theatre of white marble. P. has a library with 20,000 vols., a Lyceum (formerly a Jesuit College), a school of design, a lunatic asylum, and several charitable institutions. A University, founded here in 1724, was suppressed at the Revolution. The chief industries of the place are turning, flax-spinning, dyeing, cutlery, and the manufacture of canvas, leather, carpets, chocolate, &c. P. has a great trade in Jurançon wine, produced in its vicinity, in corn, marble, lime, tin, leather, skins, paper, resin, and building timber. Pop. (1872) 27,300. P. was the birthplace of Bernadotte (see KARL XIV.). Not far from P. lies the little town of Lescar, which has a cathedral with the tombs of Marguerite of Valois, Catharine of Navarre, Jeanne d'Albret, and other princely persons of the House of Béarn.

Pauchon'ti or **Paul'ey Tree**, are respectively the Malay and Tamul names for *Isonandra acuminata*, a large E. Indian tree brought under the notice of the British Government in 1857 by Dr. H. Cleghorn as likely to prove of considerable economic value. It has a close affinity to *I. gutta*—the gutta-percha tree of commerce—yielding, like it, a non-conducting gum elastic. The trunk rises to an immense height without branching, and the hard, tough wood proves useful in carpentry, &c. It is common in the densely-wooded tracts of Coorg and the Cochin territories.

Paüer, Ernst, composer and pianist, was born at Vienna, December 21, 1826. A son of the great Mozart was among his teachers. While Director of Music at Manz (1847-51), he composed several works, including the operas *Don Riego* and the *Masques Rouges*, and several concertos for the pianoforte. Since 1851, in which year he was received with enthusiasm at the London Philharmonic Concerts, he has principally resided in England. His opera *La Fiancée* was produced at Mannheim in 1861. P. gave six lectures with musical illustrations in chronological order at Willis' Rooms in 1864, and is well known throughout the country as a lecturer and pianist. He has published many sonatas, tarantellas, vases, songs, &c., among his most popular pieces being *Pensées Fugitives* (1854), two Hungarian melodies for the pianoforte (1865), *Recollections of Meyerbeer* (six transcriptions, 1867). He has arranged and edited the works of many classic composers: Beethoven's *Overtures* (1856) and *Symphonies* (1868); Weber's *Complete Pianoforte Works* (1872); *The Schumann Album* (1872); Chopin's *Nocturnes*, *Mazurkas*, and *Valses* (1872-74); 32 *Songs*, and the *Complete Pianoforte Works of Schubert* (1874); *The Complete Works of Mozart* (1874), &c. P. is the author of a primer on the *Pianoforte* (Novello, Ewer, & Co. 1878).

Paul, the great Apostle of the Gentiles, was a native of Tarsus in Cilicia (Acts xxii. 3), born probably two or three years after Christ, of pure Jewish stock (Phil. iii. 5), a Pharisee (Acts xxvi. 5), and a Roman citizen (xxii. 25-8). The turning point of his life was his conversion, which took place at Damascus, whither he had gone as a persecutor of the Christians, and in consequence of the remarkable occurrence which took place on the road (Acts ix.). But the life and work of this remarkable man, who fills so important a place in the history of the early Church, can only be properly understood if the relation in which he stood to the Apostles be remembered. The religion of Jesus, as it was understood and taught by the Apostles who took up the Master's ministry and carried on the work, was simply a reform of Judaism. Their distinctive doctrines were that Jesus was the Messiah (q. v.), that he had risen from the dead, and would soon return to establish His kingdom, to overthrow the Roman dominion, and exalt the Jewish nation; being at the same time zealous in their recognition of the Jewish law, which, however,

was repudiated by the converts from among the Hellenistic or Greek-speaking Jews. Now, as a citizen of Tarsus, and a disciple of the liberal-minded Gamaliel (q. v.; Acts xiii. 3), P. must have had much in common with these Hellenistic converts, but his education in the Rabbinical school at Jerusalem must have superficially strengthened his attachment to Judaism; and being at the time hot-headed, impulsive, and blindly zealous, he held a liberal theology in an illiberal spirit. Thus it happened that he was a ringleader in a persecution which seems to have been directed solely against the Hellenists, for the Apostles were residing at Jerusalem unmolested all the time. But it was quite natural, according to the bent of his mind, and as a consequence of his direct antagonism to the Hellenists, that after his conversion he should belong to that party. At any rate, from the time when he began to preach, he continued at variance with the Judaizing party (cf. Acts vi. 1, Gal. i. 2). At Antioch, where he and Barnabas—a Hellenist—began to preach, the disciples received and accepted the name 'Christians,' that is, they virtually made a declaration that it was unnecessary to become Jews. The Apostles thereupon sent emissaries to Antioch to counteract this teaching, and these taught the brethren, 'Except ye be circumcised after the manner of Moses, ye cannot be saved' (Acts xv. 1). In consequence of the commotion caused by this disagreement, P. and Barnabas were sent to Jerusalem to confer with the Apostles about this question. The result of the conference was that an agreement was made by which P. was to preach to the heathen, while the Apostles confined their ministrations to the circumcised Jews. Accordingly P., in company with Silas, made a second missionary journey in Asia Minor, and then passed over into Europe, visiting the cities of Philippi, Thessalonica, Berea, Athens, and Corinth, but everywhere rejected and persecuted by the Jews. After a journey to Jerusalem and Antioch he arrived at Ephesus, where he was better received by a society of Jews who had been baptized with John's baptism, in other words, who had learned to esteem personal righteousness above ceremonial observances, and were therefore more prepared to receive the teaching of P. On his return to Jerusalem, however, after making another tour through Macedonia and Greece, the Jewish persecution again broke out, in connection with which it is a very significant circumstance that the apostolic Church was at this time also entirely unmolested. P. is denounced to the authorities, and only saved from death by an appeal to Cæsar, in consequence of which he had to be removed as a prisoner to Rome, where all trace of him is lost (Acts xvi.—xxviii.).

From this brief survey it appears that during the whole time of his ministry P. stood apart from the Apostles, by whom his claim to the apostleship was not admitted, knowing as little of their doctrine as he did of themselves (cf. Gal. i. 17-23), and teaching in opposition to them that Judaism was abrogated by Christianity. It is just as clear that the whole Christianity of the West, that is, of Christendom, emanated from him alone. The doctrinal teaching of P. is best seen in the Epistle to the Romans. It is generally assumed that the 'Brethren at Rome' were Christians. Some, however, are of opinion that they were a society of Jews, holding the religious philosophy of Philo (q. v.) of Alexandria, who had introduced the conception of the Platonic Logos into Jewish thought, and who had visited Rome about twenty years before P. addressed his epistle to the brethren there. Now, like the author of the Fourth Gospel, P., who had become acquainted with Philo through Gamaliel, in defining the nature and office of Christ, uses the identical epithets which Philo applies to the Logos (see Jacob Bryant's *Sentiments of Philo Judæus Concerning the Logos*); but, like Bryant also, he goes one step beyond Philo in identifying the Logos with an actual person, Jesus. In this way it is explained how, while the religion of Jesus became extinct on purely Jewish territory, it took root and flourished among the Hellenistic communities, for whom it was an easy process to exchange the speculative Logos for the more definite conception of a personal Christ. It thus appears that, while P. was all along, practically at least, unrecognised by his Jewish brethren, the legitimate Apostles of Christianity, he was by far the most eminent Apostle of which Christianity can boast. He was the first real intellectual exponent of the religion of Jesus as a universal religion; and at the same time the great prophet of absolute religion, that is, of religion divested of Church usages and rites. His mighty influence in the foundation of Christianity has indeed been acknowledged, while all the time he has been misunderstood and

credited with opinions which he never held. When his character comes to be read in a truer light, and his teaching to be better understood, he will be more highly revered even than he is. See Smith's *Dictionary of the Bible* (1863), Conybeare and Howson's *Life and Epistles of St. Paul* (Lond. 1853), Reuss's *Hist. de la Theol. Chret.* (3d ed. Strasb. 1864), Baur's *Paulus* (Eng. trans. Lond. 1873), Zeller's *Apostelgeschichte* (Eng. trans. Lond. 1875), Pfleiderer's *Paulinismus* (Eng. trans. Lond. 1877).

Paul, the name of five Popes.—**P. I.** (757-767) succeeded his brother Stephen II. He was a moderate and pious pontiff, and a close ally of Pippin, the Frankish king.—**P. II.** (Pietro Barbo) succeeded Pius II. in 1464. He failed to keep the promises made at his election, viz., to restore the ancient discipline of the Church and to summon a general council within eight years; accordingly, to appease the cardinals, he granted them the distinction of the purple robe and the red hat. In 1466 he excommunicated and preached a crusade against Georg Podiebrad, who favoured the Hussites. In 1469 he made a league with the republic of Venice against Ferdinand I. of Naples, and fortified his frontier towards Abruzzo. He died in 1471.—**P. III.** (Alessandro Farnese), born at Canino in 1468, entered on his pontificate in 1534. He devoted himself mainly to the overthrow of 'heresy,' and to the internal reform of the Church. He summoned a general council in 1536, which met at Trent in 1545. He appears at first to have had an honest desire to reconcile the Protestants to the Church, but he refused to sanction the concessions made at the Diet of Ratisbon in 1541 by Cardinal Contarini, and in 1546, from fear of the political predominance of Karl V., he refused to aid him in his decisive measures for the extirpation of heresy, which led to the emperor's independent promulgation of the second Interim (q. v.), and may be said to have saved Protestantism in Germany. P. favoured the Jesuits, and issued a bull of deposition against Henry VIII. of England in 1538. A sagacious and far-seeing man, he did much to heal the wounds of the Church after the great schism, and seldom has any Pope been so beloved by the Romans. He died 10th Nov. 1549.—**P. IV.** (Giovanni Pietro Caraffa), born at Capriglio, in Naples, 1476, was elected in 1555 in spite of the opposition of the Imperial party. Animated by a patriotic love of Italy and a peculiar hatred against Karl V. as the oppressor of his native Naples, he lent all his influence to destroy the Spanish power in Italy and allied himself to the French, but their defeat at St. Quentin by the Duke of Alva in 1557 destroyed all his hopes and obliged him to make peace with Philip II., to whose religious scruples alone he owed the safety of his capital. From this time until his death, 18th August 1559, he laboured with great zeal to purify the Church, and with this view vigorously set in motion the Inquisition both in Italy and Spain, and originated the Index Expurgatorius (q. v.). But his severity had made him so unpopular with his subjects, that his death was the signal for a revolt at Rome, in which all his statues were broken by the mob.—**P. V.** (Camillo Borghese), born at Rome in 1552, was created a cardinal in 1596, and succeeded Leo XI. in 1605. He found himself at once engaged in a struggle with Venice, which had always been indifferent to the lofty pretensions of the Papacy. P. claimed the right of managing the tithes and of being supreme judge in all ecclesiastical causes, and laid the republic under an interdict, which, however, was resisted vigorously. The temporising of the Jesuits led to their expulsion from Venice, nor were they permitted to return after the compromise which was effected by the mediation of Henri IV. of France. P. showed his fondness for the Jesuits also in defending Suarez from the wrath of the French parliament on account of the publication of his book *Défense de la Foi Catholique*. In 1617 he renewed the ordinance of Sixtus IV. on the Immaculate Conception of the Virgin, but declined to make it an article of faith, and showed the same moderation in the case of Galileo, condemning his decisive tone in maintaining an opinion contrary to Scripture, but allowing him to hold it as an astronomical hypothesis. He died 28th Jan. 1621. See Ranke's *Die Röm. Päpste, ihre Kirche und ihr Staat im 16 und 17 Jahrh.*, and Artaud de Montor's *Hist. des Souv. Pont. Romains*.

Paul I., Petrovitch, Emperor of all the Russias, son of the Emperor Peter III. and the Empress Catharine II., was born 1st October 1754. His parents inhumanly denied him all affection; his father sought to exclude him from the

succession, and even after the latter was assassinated and Catharine was firmly seated on the throne, he was debarr'd from every action that could form his mind for empire, and surrounded by persons who watched his every step. This treatment changed his frank and open character to one of harshness and distrust. His education was intrusted to the famous statesman Count Panin, of whom he was a close friend till his death. In 1762 P. inherited from his father the Götterp part of Holstein, which in 1773 was yielded to Denmark in exchange for the Granddums of Oldenburg and Delmenhorst. On his mother's death (1796) P. ascended the throne, and began his reign with clemency, taking mild revenge on his father's murderers (see O'LOFF), and freeing Kosciusko from prison. But the French Revolution, and the liberal ideas it diffused throughout Europe, filled him with disgust and fury. He instituted a strict censorship of the press and examination of all foreigners travelling in Russia; established a formidable secret police; demanded the most scrupulous and severe discipline in the army; banished great numbers to Siberia; forbade round hats and all French fashions; compelled the soldiers to use hair-powder and wear long queues; and forced his nobles when they met him to leave their carriages and kneel before him. P. took part in the second great coalition against the French Republic, and sent Suvaroff and Korsakoff with 100,000 men to Switzerland and Italy in 1798-99. But he soon became distrustful of Germany, and yet more so of England, especially as the latter would not resign to him the island of Malta, after P., who saw in the Knights of Malta a support for kingly power, had allowed himself to be appointed Grand Master of the Order, though he belonged to the Greek Church, and the Pope objected to the choice. He laid embargo on all English ships in Russian ports, and in 1801 concluded with Denmark and Sweden the 'Armed Neutrality' to counteract England's superiority at sea. The English fleet that did battle at Copenhagen Roads was to have gone on to Kronstadt, but the sudden death of the Emperor changed the situation. His despotic rule and rash policy had made him very unpopular among all classes, and a conspiracy was formed to take his life. On the night of the 23d-24th March 1801, the conspirators, headed by General Count Pahlen, governor of St. Petersburg, the brothers Suboff, and Generals Bennigsen and Uvaroff, entered his bed-chamber, and ordered him to sign a declaration of abdication. P. refused, and a scuffle ensued, in which either Nikolas Suboff or Bennigsen strangled him with a scarf. Pahlen opened the window, proclaimed the Emperor's death, and made the troops drawn up near the palace swear allegiance to Alexander I. P. was twice married: in 1773 to Wilhelmine of Hesse-Darmstadt (in the Greek church called Natalia Alexievna), who died childless; in 1776 to Sophie Dorothea Auguste of Württemberg (called Maria Feodorovna), who died 1828, and by whom he had four sons, Alexander I., Constantine, Nikolas I., and Michael (1798-1849), and six daughters, of whom Catharine (1788-1819) became Queen of Württemberg, by marriage with King Wilhelm I., and Anna (1795-1865) Queen of the Netherlands, by marriage (1816) with King Wilhelm II. See *Leben Paul's I.* (Frankf. 1804).

Paul, Vincent de. See VINCENT DE PAUL.

Paulding, James Kirk, an American writer and humorist, was born in Pleasant Valley, New York, U.S., August 22, 1779. His father was a farmer, of Dutch extraction. After supplementing a meagre education by a course of self-instruction, P. went to New York about 1800, and in 1807 began his literary career in company with his brother-in-law, Washington Irving, with whom he wrote a series of satirical papers, entitled *Salmagundi*. In 1813 he produced *The Lay of a Scotch Fiddle*, a burlesque of Scott's *Lay of the Last Minstrel*, and the year after published *The United States and England*, a reply to some articles in the *Quarterly Review*, which gained him in 1814 the post of Secretary to the Board of Navy Commissioners. He was secretary to the United States Navy (1838-41), and for twelve years was navy agent in New York, during the whole of which period he was a prolific writer. P. died at Hyde Park, near New York, April 6, 1860. His best works are *Letters from the South* (1817); *John Bull in America* (1824); *The New Pilgrim's Progress* (1828); *Tales of a Good Woman* (1829); *The Dutchman's Fireside* (1831); *Westward Ho!* (1832); *Life of Washington Irving* (1835); *The Old Continental* (1846).

Pauldrons, in armour, were plates introduced early in the 15th c. to protect the shoulders. They sometimes had pinnards, or ridges to ward off the blow of a lance, attached.

Pauli, Georg Reinhold, a German historian, was born at Berlin, May 25, 1823, and studied at the universities of Berlin and Bonn. He came to England in 1847 to prosecute historical researches in the Scotch and English libraries, and from 1848 to 1852 held the post of private secretary to Baron Bunsen, then Prussian ambassador at the English court. Returning to Bonn (1855), he was successively appointed Professor of History at Rostock (1857), at Tübingen (1859), at Marburg (1867), and at Göttingen (1870), his removal from Tübingen being due to an attack on the Württemberg Government, published by him in the *Preussische Jahrbücher* (August 1866). P. is author of *King Alfred und seine Stellung in der Geschichte Englands* (Berl. 1861; Eng. trans. 1852), a continuation of Lappenberg's *Geschichte Englands* (vol. iii.-v. Gotha, 1853-58), *Bilder aus Altenglant* (Gotha, 1860; 2d ed. 1876; Eng. 1861), *Geschichte Englands seit den Friedensschlüssen von 1814 und 1815* (3 vols. Leips. 1864-73), *Simon von Montfort* (Tüb. 1867; Eng. 1876), *Aufsätze zur Englischen Geschichte* (Leips. 1869). P. has also edited with great care and critical acumen Gower's *Confessio Amantis* (Lond. 3 vols. 1857).

Paulicians, a sect of Christians, founded by a reformer, Constantine, who appeared near Samosata about 660. Thinking that in the Epistles of St. Paul he had discovered the dualistic ideas—the opposition between flesh and spirit—with which, as a member of some Gnostic (probably Marcionite) sect, he was imbued, he desired, while preserving his dualism, to revive a pure Pauline Church. Under like-minded successors of Constantine the sect spread in Asia Minor, although exposed to continual persecution as Manichæans. Their peculiar principles were dualism, attaching extraordinary value to the authority and Epistles of St. Paul (from which they derived their name), and the rejection of all externalities in religion. About 800 the persecution against them was so bitter that many of them fled into the Saracen territory, where, at the town of Argam, they formed a frontier settlement which was troublesome to the Byzantine Empire till they were subdued by the Emperor Basil (871), and a great part of them transplanted to the neighbourhood of Philippopolis in Thrace. Here they enjoyed religious liberty, and were almost an independent State, but their power was crushed by the Emperor Alexius Comnenus (1081-1118), by whom the heresy was outwardly, although not in reality, extinguished. They survived under the guise of the Euchite monks, who at this time (1116) became known under the Slavonic form of their name, Bogomili (q. v.). See Gieseler's *Lehrbuch der Kirchengeschichte* (Eng. trans. 1855), Neander's *Gesch. der Christl. Rel. und Kirche* (Eng. trans. 1858).

Paulinus, a follower of Augustine, the first missionary to the English, is memorable as the chief agent in the conversion of the Northumbrians to Christianity during the reign of Eadwine (q. v.). The story of the great debate among the Northumbrian witan is one of the immortal passages in Bede. In 625 P. became Archbishop of York. On the overthrow of Eadwine at Hatfield, 633 A.D., by the combined forces of Penda, the heathen king of Mercia, and Cadwallon the Welsh prince, P. left the North and returned to Kent, where he was made Bishop of Rochester, and where he died, 10th October 644. The restoration of Christianity in Northumbria was due to the zeal of Iona (see AIDIN), and not of Canterbury. Bede's *Hist. Eccl. Gent. Angl.* (Moberly's ed., Macmillan & Co., 1869); Green's *History of the English People* (Macmillan & Co., 1877).

Paulus, Lucius Emilius, surnamed **Macedonicus**, a distinguished Roman general, son of the consul of the same name that fell at Cannæ, was born about 229 B.C. In 193 he was appointed proconsul of the province of Further Spain, where he waged a war against the Lusitani, in which he was ultimately victorious. In 182 he was associated in the consulship with Cn. Baebius Tamphilus. When above sixty years of age, he was elected consul a second time 168, and intrusted with the command of an army in the war against Perseus, King of Macedonia, whom he completely defeated near Pydna on the 22d June of that year. P. arrived in Italy in 167, and was honoured with one of the most splendid triumphs Rome had ever seen. His successes, however, were greatly embittered

by the loss of his two sons, one of whom died only five days before, and the other three days after his triumph. P. died a.c. 160. He was declared by a contemporary to be "one of the few Romans of that age to whom one could not offer money." See *Plutarch's Life of L. P.*

Paul's Cathedral, St., London, the grandest Protestant church in the world, lies in the heart of the City, on a site associated with an ecclesiastical building from an early time in the history of Christianity. It is stated that two successive churches existed on the spot before the year 610, when under the reign of Ethelbert, King of Kent, Melitus, the first Bishop of London, was appointed, and a structure reared which lasted till 1083. Old St. Paul's, built between that date and the year 1315, was a noble and imposing building, 690 feet in length, 130 in breadth, with a spire ascending to a height of 520 feet. At one time it was divided into 76 chantry chapels, employing the services of 200 priests. The sum of £104,330 was paid in repairing it in the reign of Charles I. It perished in the great fire of 1666. (See Sir W. Dugdale's *History of St. Paul's Cathedral*, 2d. ed., 1658). The present Cathedral was built 1675-1710, under one architect, Sir Christopher Wren, and one master-mason, Thomas Strong. The expense, amounting to £747,954 2s. 6d., was met partly by public subscription, and partly by a small duty on coals. Wren was thwarted in his original plan of encircling the building with a large triangular piazza, and his magnificent work is hemmed round by irregular buildings, the best, but by no means an adequate approach, being from Ludgate Hill. The exterior of the building, with its massive dome, towering above the giant city, is hardly unfamiliar even to those who have not seen it. The material is Portland stone. The ground plan is in the form of a Latin cross, with a projection on each side of the western extremity. A handsome flight of grey granite steps ascends from the statue of Queen Anne to the western or grand entrance, under a double portico of coupled columns, the lower Corinthian, the upper Composite in style, surmounted by a pediment graced by a number of sculptures, and having the clock and belfry towers on either side. The other entrances in the north and south transepts are semicircular, under porticos with six Corinthian columns. The apex or eastern end is semicircular and plain in style. There are really three domes; an inner, an outer, and an intermediate one of brick. From the two outside galleries of the dome a magnificent view of the city and surrounding country can be obtained. The dome is crowned by the stone lantern, ball, and cross. The length of the cathedral from E. to W. is 500 feet, the extreme width 250 feet, the exterior diameter of the dome 189 feet, and the circumference of the whole building 2292 feet. The height from the foundation to the cross is 404 feet, or from the level of the street 360 feet. The charge for a visit to every part of the building is 3s., but the body of the church is always open to the public, and the payment of 6d. admits to the galleries. The lofty vaulting of the interior of the central area (an octagon formed by eight massive piers, four 40 feet wide, the others 28), is sublime in effect, and the dome has a most graceful appearance, its height being equal to its diameter and one half. The whole vault consists of 24 cupolas. The dividing of the nave into a middle and two side aisles, though usual in cathedrals, is injurious to the general effect. The choir is 165 feet long. The marble pulpit is a fine specimen of polychromatic art. Great improvements of late years have been made in the decoration of the church, and particularly of the choir, and several fine stained-glass windows have been given. The organ, which formerly stood over the entrance to the choir, has been removed to the side, thus giving an uninterrupted view from E. to W., while the altar has been enlarged. Along each side of the choir are fifteen stalls, superbly carved by Grinling Gibbons, sculptor to George I. In the centre of the N. range is the Lord Mayor's stall, opposite to which is that of the Bishop of London. At the extremity of the S. range is the episcopal throne. Choral service is performed twice every week-day, at ten in the morning and three in the afternoon, and three times on Sundays, sermons being preached on holidays and every Wednesday and Friday in Lent. A morning service is held daily in the Morning Chapel at the W. of the building, which has recently been elegantly decorated with fine marble work and elaborate marble pavement. Among the annual special services, the sermon in May on behalf of the

sons of the clergy, and the assemblage of charity children on the first Thursday in June may be mentioned. The latest great historical service was the national thanksgiving for the recovery of the Prince of Wales in May 1892. The earliest monument erected in the building was that to John Howard (1796). There are now 64 monuments, 29 of which are to military and 19 to naval heroes. The public expense of these to Sir R. Abercromby, the Marquis of Cornwallis, Earl Howe, Lord Nelson, and Lord Rodney, amounted in each case to £5000. In the crypt, a vast vault divided like the body of the cathedral into three parts, lie the remains of some of our most famous artists, Wren, Reynolds, Lawrence, Turner, Landseer, &c., of cathedral dignitaries, and of the Duke of Wellington, Lord Nelson, and others of the illustrious departed. Many objects of interest remain which space fails to describe, the geometrical staircase of 90 steps hanging together without visible support, the great bell, weighing 11,474 lbs., originally cast in the reign of Edward I., the whispering gallery with its acoustical wonders, the paintings in the eight compartments of the dome by Sir J. Thornhill representing events in the life of St. Paul, the mosaic pictures of Isaiah and St. Matthew by Salviati in the spandrels of the dome, the library, which contains 9000 volumes and some ancient manuscripts, &c. The members of the cathedral consist of the dean, 4 canons residentiary, 30 prebendaries, 12 minor canons, and 6 vicars choral.

Paulus, Ægineta, a celebrated Greek medical writer, was born at Ægina in the 7th c. A.D. Nothing is known regarding him except that he travelled and practised in several countries. His great and only extant work has no exact title, but is commonly called *De Re Medica Libri Septem*. Of these seven books, which are chiefly a compilation from former writers, the sixth, relating to surgery and the treatment of fractures and dislocations, is the most valuable. The seventh book contains an account of the properties of various medicines. According to Suidas he wrote several other works; and the Arabic authorities, who held him in great veneration, ascribe to him two treatises, *De Mulierum Morbis* and *De Puerulorum Vitæ Ratione atque Curatione*. There are three Latin translations of his great work, the last by Cornarius appearing at Basel in 1556. An English translation by Francis Adams was published in three vols. (Lond. 1846-48).

Paulus, Heinrich Eberhard Gottlob, an eminent German theologian, and a leader of the Rationalistic school which flourished about the beginning of this century, was born 1st September 1761, at Leonberg, near Stuttgart. Having distinguished himself at Tübingen University as a student of the Semitic languages, he made a tour through the principal libraries of Germany, Holland, England, and France, under the patronage of the Baron von Palm. In 1789 the friendship of Griesbach procured him the chair of Oriental Languages at Jena, which he held till the death of Döderlein in 1792, when he became Professor of Theology in his place. In 1811 he was appointed to the chair of Exegesis and Church History at Heidelberg, a position he occupied till old age forced him to retire in 1844. P. died at Heidelberg, 10th August 1851. P. thought that the superhuman origin claimed for Christianity was mainly a superstition, and laboured to prove that the miracles were in no sense real. His crude rationalism was never formidable, and vanished before the subtle and suggestive scepticism of Strauss. His chief works are *Sammlung der Merkwürdigsten Reisen in dem Orient* (Jena, 7 vols. 1792-1803); *Philologisch-Kritischer und Historischer Commentar über das Neue Testament* (Leips. 4 vols. 1800-4); *Leben Jesu* (Heidlb. 2 vols. 1828); and *Exegetisches Handbuch über die drei ersten Evangelien* (Heidlb. 3 vols. 1830-33). See P.'s *Skizzen aus meiner Bildungs- und Lebens-Geschichte* (Heidlb. 1839); and Reichlin-Meldegg's *P. und seine Zeit* (Stuttg. 2 vols. 1853).

Paulus Diaconus (so called from being deacon at Aquileia) was born at Friuli about 730, was educated at Pavia, and became private secretary to Desiderius, King of the Lombards, and tutor to his daughter. For his pupil he wrote his *Historia Romana*, which was an enlargement of Eutropius (q. v.), but contains nothing not found in other writers. It was very popular during the Middle Ages, and numerous MSS. exist. In 781 he was in the monastery of Monte Casino, but is found soon after in the Frankish kingdom assisting Karl the Great with his educational reforms. For him he compiled his Homiliarium

(q. v.). About 787 P. returned to Monte Casino, where he died in 797. Of his other works, the chief were his *Hist. Langobardorum* and *Gesta Episcoporum Mediensium*. See a critical life of P. D. intended as an introduction to a collected edition of his writings by Professor Felix Dahn (Leips. 1876).

Paumbaum (*Pambam*), a town in the district of Madura, Madras Presidency, British India, on the N. W. extremity of the island of Rameswaram, which runs out towards Ceylon to form Adam's Bridge across Palk Straits. Pop. (1871) with the adjacent town of Rameswaram, 9407. P. has given its name to the narrow channel by which coasting craft avoid the circuit of Ceylon. Since 1822 this channel has been under the care of Government; by convict labour it has been deepened 14 feet, and a lighthouse has been erected. P. is annually used by 2100 native vessels, with an aggregate tonnage of 174,000.

Paupers. See POOR-LAWS.

Pausanias, the son of Cleombrotus, and regent of Sparta for his cousin Pleistarchus, at the head of the allied Greeks defeated the Persians at the battle of Platea (479 B.C.), and afterwards marched on Thebes, which he forced to give up the heads of the Persian party. In 477 he subdued the greater part of Cyprus and captured Byzantium—successes that inflamed his vanity and led him to form the design of making himself master of Greece. He entered into treasonable negotiations with Xerxes, assumed the dress and manners of a Persian, and awakened such dissatisfaction and alarm that the ephors recalled him to Sparta. Placed on his trial and acquitted, he at once resumed his schemes, even inciting the Helots to revolt by holding out the hope of liberty. Accident revealed the plot, and P. was forced to take refuge in the temple of Athene Chalceicus, on the Spartan acropolis. The populace built up the door, his mother assisting in the task, and then stripping off the roof, left him to a lingering death (circa 468). See Thirlwall's *History of Greece* (vol. ii.).—P., a Greek geographer who flourished in the latter half of the 2d c. A.D. and published an itinerary, *Periēgēsis tēs Hellados*, in ten books, from which we gather that he was a native of Lydia, and had travelled through Greece, Asia Minor, Egypt, Libya, and Italy. This work is mainly devoted to a description of works of art, but it is also our chief authority for the topography of ancient Greece. Its style, based on that of Herodotus, is disfigured by carelessness and obscurity, defects that are most apparent in the first book. The *editio princeps* was printed by Aldus (Ven. 1516), and there are recent editions by Dindorf (Par. 1845) and Schubart (2 vols. Leips. 1838-39), and translations into English by Thomas Taylor (3 vols. 1794), into German by Schubart (9 vols. Stuttg. 1857-66), and into French by Clavier (6 vols. Par. 1814).

Pavement is a street or roadway surface specially prepared with stones or blocks of wood or other material built together, or of a covering of asphalt or cement. P. in towns originally consisted of large rounded boulders rudely set together, in the necessarily wide interstices of which all kinds of filth lodged. Such a P., originally not very level, soon became very uneven owing to the unequal support the rough blocks had, and the street was quickly cut up into ruts and ugly depressions. This kind of P. was followed by an improved form, in which unsquared blocks of whinstone, granite, &c., were packed into a rough rubble causeway; examples of such a P. are common at the present day in second-rate streets. To Mr. Telford, the eminent engineer, is due the credit of first suggesting and introducing pavements of properly squared and dressed blocks set upon a thick foundation of broken stones. In 1824 Telford recommended for certain London streets dressed stones of three classes, as follows:—

	Width.	Depth.	Length.
For Streets of First Class,	6 to 7½ in.	10 in.	11 to 13 in.
Second do.,	5 to 7 in.	9 in.	9 to 12 in.
Third do.,	4½ to 6 in.	7 to 8 in.	7 to 11 in.

For first-class pavements the size of the 'sets' or blocks was gradually reduced from these measurements till in 1840 3-inch granite sets with a depth of 9 inches were adopted, and that now forms the standard for P. of the best quality. Wood P. of a rude kind has been known in Russia for several centuries, and in various countries plans for forming P. of wood have been suggested. In all cases the blocks of wood are placed on end, with the fibre of the wood in a vertical position. Wood P. on Carey's

plan was introduced in London in 1841, and some of it continues to the present day; but that which has met most extensive favour is the Improved Wood P. introduced from the United States under Nicholson's patent. It is now in very general use in London, where it was introduced in 1871, and in Edinburgh, Glasgow, Birmingham, and other great towns there are many examples of it. According to the most recent method of laying this P., a bed of sand or dry earth is prepared and formed to the outline of the street. Above this is put a thin bed of concrete, over which is placed a layer of 1-inch boards, which have been previously steeped in tar, and on this boarding the wooden sets or blocks, 3½ in. wide, are placed. The joints between the courses, about ½ in. wide, are filled for half their depth with artificial asphalt, and above that they are filled to the top with a grounding of gravel and lime rammed hard home. Asphalt P. is made in many ways, and is now much employed both for foot-paths and carriage-ways. There are two kinds of asphalt—natural and artificial—in use. The principal natural asphalt used for P. are Val de Travers and Limner. Val de Travers P. is made first by powdering the natural rock by heat, spreading the powder over a prepared concrete surface while it is still hot, and compressing it with heated irons into a homogeneous mass. It is usually made from 2 to 2½ inches thick. Val de Travers Mastic P. and Limner P. are prepared by melting the natural asphalts with the addition of a little bitumen, mixing the fluid mass with dry shingle, and spreading it evenly over a prepared concrete bottom. In addition to these, and the P. made from the asphalt of gas-tar, there are a great number of other asphaltic P. compositions. Among other varieties of P. deserving of notice is the concrete P. introduced by Mr. Mitchell, of Inverness, a piece of which laid in George IV. Bridge, Edinburgh, has yielded most satisfactory evidence of its durability, cleanliness, and economy. Foot-pavements are best composed of large broad flagstones, about 3 inches in thickness, carefully laid on a well-rammed foundation, and kept in their places by the kerb stone which confines and separates both flagging and P. The flagstones mostly used are obtained from Old Red measures in the neighbourhood of Arbroath and similar deposits in Caithness, Cromarty, and Nairn. In many English towns flagstones of a durable quality from the Millstone Grit series of Carboniferous rocks are used for foot P., and other coal measure sandstones find similar employment, although they are more friable and porous, thus retaining wet and damp for a long time after rain.

Pavia. See HORSE-CHESTNUT.

Pavia, a city of N. Italy, on the River Ticino, 3 miles above its junction with the Po, and 23 miles S. of Milan by canal and railway. The river is here navigable by steamboats. P. is a fine old town, with wide streets and strong walls, but there remain only nine of the hundred towers which gave it the name of *Città di Cento Torri*. A covered bridge, 708 feet long, built in 1351, connects P. with the suburb of Borgo Ticino. From this extends in a straight line N. to the Porta di Milano the finest street in P., named the Corso Vittorio Emanuele. The finest churches are the cathedral (begun in 1484, and still unfinished), in the splendid chapel of which were deposited, prior to October 1842, the ashes of St. Augustine; San Michele, a noble Romanesque building (11th c.); S. Maria del Carmine (1375), a fine brick edifice; S. Maria Coronata (1492), with fine paintings; and San Pietro, now a ruin, from which the remains of Boethius (q. v.) and the superb monument to St. Augustine have been transferred to the cathedral. The university of P., traditionally the oldest in Europe, is said to have been begun by Karl the Great, but was really first 'constituted' in 1361 by Galeazzo Visconti. It has thirteen colleges, with the three faculties of law, medicine, and philosophy, rich natural history collections, a botanic garden, a library of 175,000 volumes, and in 1874-75 had 619 students and 51 professors. P. is the seat of a bishop, has a hospital and lyceum, a school of art with a picture gallery and splendid collection of more than 5000 engravings. The old castle, built 1360-69 by the Visconti, is now a barrack. In the neighbourhood is the famous Carthusian monastery, Certosa di Pavia (q. v.). P. has a great annual fair, and considerable trade in wine, corn, silk, rice, coffee, and Parmesan cheese. Pop. (1874) 29,618. P., the ancient *Ticinum* (afterwards *Fapia*, whence the modern name), was from 568 to 774 the capital of the Lombard kings. Taken by Otto I. in 951, it was the steady ally of the Emperors during the Guelph and

Chibelline wars. Near it, in 1525, was fought the famous battle of P., in which François I. was defeated and taken prisoner by the Emperor Karl V. It subsequently came under Milan, with which it fell to Austria. In 1796, and again in 1848, it was the theatre of a revolt. In 1859 it became part of the kingdom of Italy.

Peacocks, the peacock family, distinguished from other Raptorial birds by the large tail-coverts of the males. See **PARACOCK**.

Panna (*pan*, from Sansk. *parna* = a leaf), the aromatic leaf of the *Piper betel* or *Chamuna betel*, which is universally chewed by the natives of India, acting as a carminative and antacid tonic. It is rolled round a few small pieces of the *Areca* or *supari* nut, with a little caustic lime, a few heads of spice, and sometimes a little catechu. Inclosed in gold paper, it forms a common present to guests, &c. The European term 'betel' is derived from the Bengali *bita*, a corruption of the Sanskrit *vitāṭa*. Its cultivation, which is monopolised by a special caste, is highly remunerative, though a large initial outlay is required on the *barra* or P. garden, which is a kind of leafy hothouse.

Pawnbroking. The Roman law regarding *Pignus*, or pledge, in many respects resembled that of England regarding P. But the Roman term was much more comprehensive, embracing matter which the law of England deals with under the terms *Lien* (q. v.), *Mortgage* (q. v.), and some other. *Pignus* could be created by judicial sentence; as, by decree of the praetor empowering a creditor to take his debtor's goods in security. There was also among the Romans a *Tacita Hypotheca* which existed by law (*ipso jure*) independent of the consent of parties. Thus, legatees and *fideicommissarii* (see **FIDUCIARIAL**) had a *tacita hypotheca* over that portion of the *hereditas* from which the legacies and *fideicommissum* were payable. The pledgee was bound to restore a *pignus* on payment of the debt for which it had been given. The Roman system appears to have been very gradually developed; and it cannot be shown that any branch of it ever took the exact form of the modern P. This, however, we find to have existed in medieval times among the wealthy traders of Florence. It is supposed, indeed, that the bridge of the business—the three balls—owes its origin to the armorial bearings of the Medici. In England, we find that P. was carried on by the Italian traders of Lombard Street in the times of the earlier Plantagenets. In the reign of Edward I., a statute gave a message to these traders on the site of the busy Lombard Street of to-day. In the reigns of James I. and Charles I., the goldsmiths were in the habit of lending on pawn. Various efforts have been made at home and abroad to work the charitable and commercial principles of P. into harmony, but these have not been successful. In one instance, during the commercial panic of 1825, by the failure of a *Mont de Pitié*, a capital of £400,000 was lost. Similar endeavours in Ireland were equally unsuccessful.

Law in Great Britain regarding Pawnbrokers.—The Act 35 and 36 Vict. c. 93 consolidates previous Acts relating to P. in Great Britain, but it does not extend to Ireland. The provisions of the Act extend to keepers of all shops for the purchase or sale of goods, when there is an understanding, expressed or implied, that these may be redeemed or repurchased on stated terms. No provision of the Act applies to a loan of above £10, or to the pledge on which such loan is made, nor to the pawnbroker or pawner in relation to such loan. A pawnbroker must keep certain books and documents, and on taking a pledge in pawn, a ticket must be given, on which must be printed certain specified provisions of the Act. There are schedules annexed to the Act specifying rates of profit and charges. Every pledge is to be redeemable within a year and seven days, after which a pledge for a loan of 10s. or less becomes the property of the pawnbroker. A pledge for a loan of above 10s. is then to be sold by public auction under stated regulations. The holder of the pawn-ticket for such a loan may, any time within three years from the date of the auction, inspect the entry of sale, which must be made in the pawnbroker's book, and when the pledge appears to have been sold for more than the amount of the loan and the profit due at the date of sale, with necessary costs and charges, the pawnbroker must on demand being made pay the surplus to the holder of the ticket; but if various pledges have been sold on account of various loans to the same person, and

the book shows a deficit on one transaction and a surplus on another, the pawnbroker may set off the one against the other, and he is thus liable only to pay the balance, if any. A special contract may, however, be made with regard to a loan of above £2. The holder of the pawn-ticket is presumed to be the person entitled to redeem the pledge, and the ticket must be delivered when redemption is required. Provision is made in the event of the ticket being lost or destroyed. It is an offence under the Act for a pawnbroker to take an article in pawn from any one appearing to be intoxicated, or apparently under twelve years old, or on Sunday, or on other specified holidays. Conviction of fraud, or of knowingly taking stolen goods, may, if the court thinks fit, be punished by forfeiture of licence.

Pawnees, a tribe of American Indians, hereditary enemies of the Dakotas, formerly occupying Central Nebraska. They are superior physically to most Indians of the Plains, and at one time numbered 2000 warriors, but have been greatly reduced by wars with the Sioux. They removed to the Indian Territory (q. v.) in 1875.

Pawtucket, a town in Rhode Island, U.S., about 4 miles above Providence, with which it is connected by a horse railway, has twelve churches, a library, and one newspaper. The river has here a fall of 50 feet, affording immense water-power to the town, one of the chief places in New England for the production of machinery and cotton fabrics. Pop. (1870) 6619.

Pax (Lat. 'peace') was a goddess of peace worshipped by the ancient Romans, in whose honour a festival was celebrated annually on the 30th April. In the Christian Church the P. was a small tablet of silver, ivory, or other material, by means of which the kiss of peace used to be circulated through a congregation. In primitive times it was the practice for Christians to give each other a kiss of peace in their assemblies for worship. But as this practice was sometimes abused, the P. was introduced, which was first kissed by the officiating minister, by him handed to the deacon, and by the latter to the people, who all kissed it in turn.

Paxo, one of the Ionian Islands, 10 miles S. of Corfu, rises in a solitary peak, 900 feet high, and produces better olive oil than any other member of the group. Area, 10 sq. miles, pop. 5287. The chief village is Porto Gajo, or St. Nicolas. To the S.E. is the sterile islet of Antipaxo.

Paxton, Sir Joseph, architect and landscape-gardener, was born of humble parents at Milton Bryant, in Bedfordshire, in 1803. He was employed as a gardener at Chiswick by the Duke of Devonshire, who, appreciating his ability, removed him to Chatsworth, where he became director of the beautiful gardens, which were modelled from his designs, the grand conservatory which covers an acre of ground being also his production. He designed the buildings for the Great Exhibition of 1851, and the Crystal Palace at Sydenham, which, in its graceful outline, fairy-like appearance, and splendid proportions, remains a lasting monument to his genius. He also laid out the grounds in a charming manner. P. received the honour of knighthood in 1851, and sat in the House of Commons for Coventry, as a Liberal, from 1854 till his death, June 8, 1865. He was editor for some years of *Paxton's Magazine of Gardening*, and published a number of horticultural and botanical works.

Paymaster. In the army, a P., who is usually an ex-military officer, is attached to each battalion of infantry, regiment of cavalry, and brigade of artillery. His duties include the payment of officers, and of the men through the captains of their companies, troops, and batteries, and the supervision of the regimental accounts. His intromissions are checked at the War Office, to which he furnishes quarterly pay lists. He has the rank of captain, with 12s. 6d. a day on joining, and his pay is increased by 2s. 6d. a day every five years, till after twenty years' service it amounts to 22s. 6d., when he has the rank of major. Officers called control paymasters are attached to military districts. In the Royal Navy the P. (called purser till the year 1844) has charge of the provisions and stores, as well as the payment of the ships' crews. His pay on joining is 14s., with the standing of lieutenant, and increases at intervals of three years, till it amounts to 33s., after twenty seven years' service, with the rank of captain.

Paymaster-General, an officer in the British Government charged with the disposal of sums voted by Parliament. He is constituted by warrant under the sign-manual, and must be a member of one of the Houses of Parliament. The office is held by a supporter of the ministry in power, usually conjointly with that of Vice-President of the Board of Trade. The salary is £2000 a year. The offices of the P.-G. are in Whitehall, the staff consisting in 1878 of the Assistant P.-G., the Treasury Remembrancer and Deputy P.-G. for Ireland, and fifty-seven clerks of various degrees. Formerly, and until the year 1782, the office was a most lucrative one, the interest of the large sums of money in the hands of the Paymaster of the Forces having been allotted to him as salary.

Paymaster of the Household, an office in the Lord Steward's department, which has superseded that of the ancient *cofferen*. Salary, £450 per annum.

Paymaster-Sergeant, a staff-sergeant, acting as clerk to the paymaster. Pay from rs. 11d. in the infantry, to 2s. 11d. in the Royal Horse Artillery, increased by 6d. a day after three years' service in the office.

Paz (La) de Ayacucho, the largest town in Bolivia, capital of the department of the same name, is situated on the E. slope of the Andes, 12,000 feet above the sea-level, in 16° 27' S. lat., 68° 22' W. long. It was founded in 1548, and was called Nuestra Señora de la Paz till after the battle of Ayacucho (q. v.) in 1824, when its name was changed to the present form. La Paz is intersected by many ravines, but has nevertheless some fine buildings, the chief of which are the university and the cathedral, the latter being a splendid edifice. The climate of La Paz is very healthy, and the town is regarded as a sanatorium by Chilians and Peruvians suffering from phthisis. It has a large transit traffic, and is the emporium of the cinchona bark trade. Pop. (according to the *Almanach de Gotha* for 1878) 76,372.

Pea (Old Eng. *pisce*, Lat. *pisum*, Gr. *pisos*, from *plissō*, 'I winnow' or 'husk'. The word P. is erroneously formed, as the 's' (seen in *pease*) is not the sign of the plural, but belongs to the root). In its restricted rendering P. is the English name for the small genus *Pisum*, represented by the well-known esculent *P. sativum*, of which there are two varieties, called respectively the garden P. and the field P., together with an immense number of sub-varieties as the result of cultivation. The native country of the species is unknown, but it is supposed, from its ancient cultivation, to be indigenous to the S.E. of Europe and Western Asia. Into Britain it would appear to have been introduced through France and Holland early in the 16th c.; fully a hundred years however elapsed before it was grown and appreciated as a table vegetable. During the period of its cultivation for this purpose, particularly within the present century, few vegetables have become more improved, both as regards quality, earliness, and productiveness. Some of the varieties scarcely exceed a foot in height, whilst others, if allowed to attach themselves by their tendrils to stakes, climb fully 8 feet. For obtaining successive crops of the P. through the summer months, various plans are adopted by gardeners. There are indeed so many good kinds, both early and late, and so many different modes of culture, that it is almost an impossibility to state any particular selection, or say what culture it is best to adopt. Tall varieties are no longer necessary, inasmuch as there are many excellent dwarf sorts; but when there is plenty of ground and sticks for disposal, some of the former may be grown with advantage, as they generally continue in bearing longer than the latter. But in small gardens the dwarfs are always the best, as they do not shade other crops. For the 'P. sticks' the tops of trees or underwood is used, and there is none better than horn-beam. The most suitable soil is a rich friable loam, and where it is found to be deficient in calcareous matter, lime or chalk should be added. For general purposes the best manure is that of the horse and cow, with a little admixture of soot to keep away worms. If prolongation of bearing is desired, the pods should not be gathered indiscriminately, but the oldest should be removed as often as they become fit for use, for one allowed to ripen will weaken the bearing power of the plant more than many young ones. Slugs, snails, and an insect called the P. Weevil (q. v.) are the principal enemies that attack the P. whilst it is

young. There is also a maggot which works mischief inside the pod. (See P. BEETLE.) Rats and mice are apt to ferret the seeds out of the ground as soon as sown, and birds of various kinds are very destructive, especially after the pods are beginning to fill. In the 'Sugar P.' the inner tough fleshy lining of the pod is absent; the young legume of these may therefore be used like kidney-beans. Formerly, varieties of the grey P. were almost exclusively grown as a field crop; now, several that range under the garden P. have been introduced into field culture. The seeds when ripe vary from round to an irregular shape, and differ in colour also. If the outer membranous coat is removed, they become split *pease*, and are used in the making of one of the most economical and nutritious articles of diet, called P. soup. The *haulm* or straw of the plant is highly esteemed as fodder. In India the natives use the seeds parched and ground, mixed with wheat flour. Before the spread of the potato, the P. also formed a great part of the food of the working classes in England. Their flesh-forming character depends upon the large proportion they contain of the albuminoid called *legumin* (q. v.) or vegetable casein; this exists as a part against 24 of starch, instead of 1 to 5 in wheat, and 1 to 10 in rice, suggesting therefore that the P. should be generally used with other foods rich in starch, sugar, fat, oil, or non-nitrogenous nutrients. A second species of *Pisum* (*P. Aucherii*) occurs in Alpine elevations of the Taurus. The genus itself is chiefly distinguished from *Lathyrus* (q. v.) by certain differences in the formation of its style, and to the latter belong the sweet P. and the everlasting P., whilst the wood or heath P. will be found referred to as *L. macrorrhizus*, under the sub-genus *Orobis*. The grain or chick P. is a species of *Cicer* (q. v.), and the important article of diet in India called the *cajan P.* is often termed the *Pigeon P.* (q. v.).

Pea-Beetle (*Bruchus pisi*), a species of *Coleoptera* (q. v.), so named from the habit of its larvæ to feed upon peas. It is found in N. America and in S. Europe. The length of the mature insect is about a quarter of an inch; its colour is black, varied with white and yellow spots.

Pea-body, George, D.O.L., an American philanthropist, was born of poor parents, at Danvers, Massachusetts, 18th February 1795. After receiving a scanty education he was apprenticed at the age of eleven to a grocer in Newburyport. He afterwards removed to Georgetown, where he became partner in a mercantile business. In 1815 he removed to Baltimore, and soon afterwards opened branch houses at New York and Philadelphia. In 1838 he settled in London, where he established a banking-house in 1843, and amassed a large fortune. In 1852 P. aided Mr. Grinnell in fitting out Dr. Kane's Arctic Expedition to the extent of \$10,000, and in the same year he founded an Educational Institute in his native town with \$20,000, afterwards increasing the total endowment to \$200,000. During a visit to the United States in 1857, P. gave \$300,000 for the foundation of a scientific and literary institute at Baltimore, the endowment of which he subsequently increased to \$1,000,000. In 1862 he crowned his munificence by a gift of \$2,500,000 to build lodging-houses for the poor in London. During another visit to the United States in 1866, he endowed two chairs, one of archaeology at Harvard College, and one of physical science at Yale College, with a sum of \$150,000 each, established a 'Southern educational fund' of \$2,100,000, and devoted \$300,000 to other public purposes. Queen Victoria offered him a baronetcy, and on his declining, presented him with her portrait; while the Corporation of London conferred on him the freedom of the City, and erected a statue of him in the Royal Exchange, which was unveiled July 23, 1869, by the Prince of Wales, during the absence of P. on his last visit to the United States. While there, he gave \$150,000 to found a museum at Salem, Massachusetts; \$60,000 to Washington College, Virginia; \$50,000 for an institute at North Danvers; \$300,000 to Phillips Academy, Andover; \$25,000 to Kenyon College, Ohio, and \$20,000 to the Maryland Historical Society. In the previous year P. had endowed a school of art at Rome. He died at London, November 4, 1869. His remains, after receiving funeral honours in Westminster (November 12), were conveyed to America in a British man-of-war, and buried in his native town, now called Peabody. By his will, several other large sums were left to various institutions, and the remainder, amounting to about \$1,000,000, to his relatives. P. was unquestionably the most generous and bene-

fiorent philanthropist of his time. The sum total of his wise charities reaches an almost fabulous figure.

Peace, Articles of the. In English law. On indictment cases being heard, justices of the peace have authority to compel any one to find security to keep the peace towards another. It must be entered on oath before a magistrate by the person making the complaint that the person against whom he complains has used threatening language towards himself or some member of his family. This is called *Articles of the Peace*, and, if satisfied that the complaint is true, it is the duty of the magistrate to oblige the offender to give his bond with securities to keep the peace for a period not exceeding a year, and failing his doing so, to commit him for a period to prison. The effects of the sureties may be seized in payment of the bond, in the event of contravention of its stipulations.

Peace, Offences against the Public. These offences are either such as are a direct breach of the public peace, or an indirect breach by tending to make others break it. Such an offence is Felony (q. v.), or a Misdemeanour (q. v.), according to its magnitude. Challenge to fight by word or letter is an indictable offence, punishable by fine or imprisonment. It is also a misdemeanour to endeavour to provoke any one to send a challenge; but using opprobrious epithets towards a man—as calling him a liar or a cheat—will not of themselves prove an intention to provoke a challenge. Persons fighting in a public place are guilty of *affray*, which is punishable by fine or imprisonment. An affray ought to be suppressed by bystanders; and by the common law, as laid down by Chief-Justice Tindal, on trial of the Bristol rioters, 2d January 1832, every private person may lawfully endeavour, without warrant or sanction of the magistrate, to suppress a riot, and, in case of dangerous riot, he may even arm himself to suppress it. It will, however, be more discreet and safer for a private person under such circumstances to act subordinately to the legal authorities. (See MEETINGS, SEDITIOUS.) Any one appearing in public armed, with intent to commit a felonious act, is punishable under the Vagrant Act as ‘a rogue and vagabond.’ Military training without the requisite legal sanction is prohibited. To accuse or threaten to accuse any one verbally, or to send or deliver a letter accusing or threatening to accuse any one of a crime punishable by death or penal servitude, is a crime which may render the criminal liable to penal servitude for life.

Peach (Fr. *pêche*, Ital. *pesco* and *persico*, ‘belonging to Persia’) is the name given to the velvety-fruited forms of *Prunus Persica* (until recently called *Amygdalus Persica*), while the Nectarine includes the smooth-fruited varieties, though it is not uncommon for each to occur on the same bough. It seems almost certain that the tree is originally indigenous in China, where its cultivation has been traced back to the 10th c. B.C. It must, however, have been early introduced into Northern India and Persia, in both of which countries it is now found apparently wild. The expedition of Alexander is probably what made it known to Theophrastus, B.C. 322, who speaks of it as a Persian fruit, and from that country it was introduced into Europe about the commencement of the Christian era. It is recorded as being cultivated in England towards the middle of the 16th c., and it is now grown in all moderately warm countries, such as the United States, Australia, New Zealand, &c. In such climates as the S. of France, the P.-trees ripen their fruit very well as standards, but in Britain it is almost always planted against a south-facing wall or transferred to the orchard-house. Though most extensively grown in the United States, from want of attention to grafting, protection, pruning, &c., the bulk of the fruit obtained is of an inferior quality. A good P. has the skin thin, of a bright red colour on its sun-exposed surface; the flesh firm, thick, and full of high-flavoured juice, and the stone of small size. As such, for a dessert fruit, it ranges in estimation next to the grape and pine-apple. It also makes a delicious preserve, and when plentiful, the pulp is sometimes fermented and a spirit distilled from it. The skin contains prussic acid, and should be removed before the fruit is eaten; the leaves, flowers, and kernel also contain this poison. What is known as the Flat P. was introduced from China about thirty-five years ago. The garden varieties of the P. and nectarine are now very numerous; some of the best are Chancellor, Rivers, Royal George, and Noblesse of the first, and Elruge, Downton,

and Violette of the latter. The heart-wood of the P. is brown, compact, even-grained, and smooth to work.

Peach Wood is another name for Nicotragia wood, of which the best description is that known commercially as Lima wood. It is the product of *Catalpa bignonioides*, a S. American species of this useful genus. For dyeing purposes it is extensively employed in the production of red and peach colour. The annual import to Britain is about 7000 tons.

Peacock (the first syllable, ‘Pea,’ is a corruption of Old Eng. *peawa*, from Lat. *pavo*, Gr. *taxis*, named from the harsh cry of the bird), a genus of Gallinaceous or Rasorial birds, belonging to the family *Pavonidae* (q. v.). The common P. is the *Pavocristatus* of ornithologists, and is noted for the characteristic ‘tail’ and hues of the male birds, the tail consisting of the upper tail-coverts, which are very long. The feathers are beautifully marked at their tips with rounded spots of golden green, and have a metallic lustre. The body plumage is also similarly tinted, but the females are dressed in sober brown, only the neck being glossed with green. The P. has a crest. The female has been known in old age, when its reproductive powers have become diminished, to assume the gorgeous colours of the male. The voice is harsh and unmusical. The P. is found wild in India, where P.-shooting is a favourite sport. The nest, which is rudely constructed, is situated on the ground. The hen in a wild state produces from twenty-five to thirty eggs or more. The period of incubation varies from twenty-five to thirty days. The eggs are white, with dark spots. The young of both sexes are at first alike in appearance, the tail of the male bird first appearing about the third year of life. The P. has been celebrated from the most ancient times. It was sacred to Juno, and according to the Greek myth, the metallic spots on the tail were the eyes of Argus, placed there by the Queen of Heaven herself. The Romans regarded the bird as a table luxury, and high prices were paid for it by the ancient epicures. Other species are the Japan P. (*P. javanicus* or *spicifer*), and the Iris P. (*P. Thibetanus*), also known as the Thibet P. and Chinese P.-pheasant.

Peacock, Thomas Love, born at Weymouth, October 13, 1785, was educated at Englefield, in Berkshire, and in 1801 commenced a course of independent reading at the British Museum. He went to Flushing as under-secretary to Sir Home Popham (1809), held an appointment at the India House (1819–56), and died at Shepperton, January 23, 1866. He was author of the poems *Palmyra* (1806) and *The Genius of the Thames* (1812), and of the novels *Headlong Hall* (1816), *Nightmare Abbey* (1818), *Crochet Castle* (1831), and *Gryll Grange* (1860). The lyrical beauty and fine comedy of his novels have charmed, as Shelley says, ‘the chosen spirits of the time,’ but their strain is ‘too learned for a shallow age,’ and their covert satire, disregard of plot, and strange blending of the Pantagruelic and Johnsonian elements, have rendered them *caviare* to the multitude. See H. Cole’s edition of his collected works, with a memoir by his grand-daughter, and a preface by Lord Houghton (Lond. 1875).

Pea-Crab, the popular name for a genus (*Pinnothere*) of *Decapodous* crustaceans, having small and rounded bodies. They are found within the shells of mussels, pinnæ, and allied molluscs, and seem to be perfectly normal tenants of the shells. Pliny’s opinion of the relations of the P.-C. and its molluscan host was that the crab warned the mollusc of approaching danger. Probably the condition is simply one of *commensalism*, or one in which the crab depends for shelter upon the mollusc, without subsisting, like a true parasite, on the tissues of its host. *P. pinna* is a common species occurring within the *Modiola* or common horse-mussel of our coasts. Its average diameter is half an inch.

Pea-Maggot, the name applied to the larva or caterpillar of a small moth (*Tortrix pisi*) belonging to the family *Tortricidae*, or that of the leaf-rolling moth. It inhabits the pod, and destroys the peas.

Pear (Old Eng. *peru*, Fr. *poire*, Lat. *pirus*) is a fruit-tree closely related to the apple, medlar, and quince, the whole belonging to the genus *Pyrus* (q. v.), it being distinguished as *P. communis*. In its natural state it grows as a shrub

or tree with branches more or less 'spinescent,' leaves ovate-oblong obtusely serrated, flowers white in corymbose cymes, fruit more or less top-shaped, with a slender stalk. It is widely distributed as a native in Europe, extending eastwards to the mountains of Asia Minor, the Caucasus, and Persia. In England, also, perhaps, it is indigenous, though, as generally met with in hedges and copses, this is not the case. To Norway it does not reach in a wild state, and its cultivation in that country stops 120 miles south of the apple. From an early period it has been grown for its fruit, for Pliny tells us that the varieties known to the Romans were numerous. It would appear also to have been long known to the people of Himalayan India. Some suppose that it was brought into use in Britain by the Romans during their occupation, while others hold that it was actually introduced by them. It is now extensively cultivated in most temperate countries, the horticulturists' art at the present time having furnished an immense series of improved varieties, rendering it one of the most delicious fruits. France and Belgium have led the way in this respect, but England now claims a head position, and excepting perhaps the jargonelle, the French specialties have gradually been replaced by superior kinds. Naturally, the P. grows in a poorer and drier soil than the apple, but to produce large crops of excellent fruit it requires, like the apple, a deep loamy soil on a good subsoil. Very often it is trained on walls and espaliers, and it is usual to graft or bud it on stocks raised from seed of the wild-plant, or if a dwarf growth is required, upon quince stocks. Besides being a dessert fruit, the P. is used for baking, stewing, compôtes, and marmalades, or is sometimes pared or dried. From the expressed juice, when fermented, perry is made. The leaves will dye yellow. (An essence employed for flavouring the sweetmeats called 'P.-drops' is an artificial composition of amyl acetate in spirit.) The light compact wood is used for turnery, tool-handles, picture-frames, &c.

The fruit of *P. nivalis*—the snow P. of mid and south Europe—becomes soft and edible through exposure to the snow. *P. variolosa*, common in many parts of the Himalayas, produces a fruit which is eaten, like the medlar, when it is half rotten. It yields, too, a hard, compact, and durable wood of a brown colour and fine grain, used for a variety of purposes. See AVOCADO P. and PRICKLY P. See Field's *P.-Culture*, and Quinn's *P.-Culture for Profit*.

Pearl (Old Eng. *pearl* and *perle*, Fr. *perle*, Ital. *perla*, Lat. *perula* (7th cent., found in Isidore of Seville), a diminutive of *pirum*, 'a pear,' so called from the shape of the gem) is the substance formed by the *Mantle* (q. v.) or shell-making membrane of certain *Lamellibranchiate* molluscs. The mantle has the power of forming in mollusca at large the *nacre* or 'mother-of-pearl' layer. This nacre consists of layers of a delicate iridescent substance, which is broken up into fine lines, and thus serves to refract the light, and to produce the exquisite play of colours that marks the interior of a shell. In certain shells (e.g., those of the pure P.-Oyster (q. v.), and of the P.-Mussel) the quality of the nacre is such, that when deposited around some foreign body it gives origin to what is known as a 'pearl.' The nucleus or beginning of this 'pearl' is found to consist of a grain of sand, or some particle of solid matter which has found its way beneath the mantle of the animal, and which has been coated over by the mantle with the nacreous or P.-secretion. That the formation of P. is purely accidental, is an idea supported by the fact that 'artificial' pearls may be obtained from common molluscs by placing foreign bodies within the mantle-lobes, when the animals will cover them with a pearly deposit. The Chinese are known to introduce within the shells of a freshwater mussel or *Unio* little metal images of Buddha, which are in due time coated over with a nacreous layer, and present a pearly picture of the deity held in the highest veneration. Linnaeus also put this idea into practical shape when he suggested to the Swedish Government that by boring a hole through the shell of the P. mussels, and by introducing grains of sand into the shell, pearls might be produced.

The chief P.-fisheries are those of Ceylon, carried on in the Gulf of Manar. Others exist in the Persian Gulf, at Panama, in the W. Indies, &c. The P.-fishing season opens in February, and lasts for one or two months. The boats are each manned by about twenty men, the divers being Tamils, and occasionally Moors. The fishing begins at daybreak, on a signal

being given by the firing of a gun. The divers in each boat are divided into two sets of five each; one gang resting while the other is employed. Each man is provided with a sinking weight or stone, weighing about 30 or 40 lbs. The usual depth to which these men descend is about 9 or 10 fathoms, but they may touch bottom at 12 or 13 fathoms. A signal cord accompanies each diver, who grasps his nostrils with his left hand, and descends carrying a net-basket, wherein the oysters are placed. From 30 to 60 seconds are the periods during which the divers remain below water, and a single diver descends several times daily. The sharks which frequent the coasts of Ceylon occasionally seize the divers, who carry a short knife for protection against their finny enemies. The oysters are piled on shore to die and putrefy, the process of forcibly opening them, by which the pearls might be injured, being thus avoided. They are next thrown into sea-water, and then carefully examined for pearls. Some are found loose; others need to be forcibly detached from the shells; the former are the more valuable. After being cleaned, the shells are split for the sake of the *nacre*, which, as imported in the finest ('silver-lipped') state, is a valuable commodity; it is used for inlaying. The less valuable kinds of nacre are the 'bastard white' and 'bastard black.' The P.-fisheries are under the control of the Government of Ceylon, and may be let to speculators. In 1797 the produce was valued at £144,000, and in 1798 at £194,000. At present the annual value of the fisheries does not exceed £30,000. The modern fisheries of the Persian Gulf are situated at Khareek and around the island of Bahrein: The Bahrein fisheries during the 16th c. were valued at 500,000 ducats annually, and in recent times they have been not less productive. Pearls vary according to the nature of the ground, the food of the animal, and other causes. The finest are called *virgin pearls* or *paragons*; *mill-pearls* is the name given to those which are large, and do not pass through any sieve in which there are more than eighty holes. Others are *vivada pearls* and *seed pearls*, the latter constituting the small specimens which pass through sieves with numerous holes, and which are sold by weight or measure. The most famous P. of which history makes mention is the one swallowed by Cleopatra, and which was valued at £80,000. Julius Cæsar presented the mother of M. Brutus with a gem worth £48,000. Philip II. of Spain possessed a Panama P., said to be worth £4000; and the 'Pilgrim P.' of Moscow, valued at an enormous sum, weighs 24 carats, and is diaphanous. The largest P. known at the present day is in the collection of Mr. Beresford Hope. It is pear-shaped, 2 inches deep, and 4½ inches in circumference, weighing 3 oz. Pearls are also obtained from the mussels of Scotch rivers. Great numbers were obtained between 1760-64, after which the fisheries fell into decline, but were revived in 1860. Those of the Tay, Earn, and Isla are especially noted. Scotch pearls range in value up to £25, but rarely reach that sum, though one set in gold and valued at £500 was shown in the Dublin Exhibition of 1865. The Conway in Wales, and several streams in the N. of Ireland, also yield these gems.

Artificial Pearls.—Excellent imitation pearls are extensively manufactured for necklaces and numerous other decorative purposes. They are composed of an exceedingly thin globule of glass open at two extremities, and coated internally with a substance possessing a fine pearly lustre obtained from the scales of the Bleak (*Alburnus lucidus*). The glass which gives the best result has an opaline lustre, and to remove its glassy aspect the blown pearls are submitted to hydrofluoric acid vapours. Artificial pearls are chiefly manufactured in Paris, but they are also made in Saxony, though of an inferior quality. Among Eastern nations, the Chinese excel in these imitations, but they attach the nacreous substance to the surface of the globules, a practice in which they are followed by the Italians.

Pearl, a river of Mississippi, U.S., which, after a generally southward course of about 250 miles, flows through Lake Borgue into the Mississippi Sound at the boundary line between Louisiana and Mississippi. Its navigation is much impeded by sandbanks, and the river in the southern part of its course frequently overflows its banks.

Pearl Ashes. See POTASH.

Pearl Barley. See BARLEY.

Pearl Mussel. See MUSSEL.

Pearl Oyster (*Margarina margaritifera*), a species of *Lamellibranchiate Molluscs* belonging not to the oyster family (*Ostracidae*), but to the *Aviculidae*.

Ceylon Pearl Oyster.

present in the common oyster.

Pearly Nautilus. See NAUTILUS.

Pearson, John, an English prelate, born at Snoring rectory in Norfolk, 12th February 1612, passed from Eton to King's College, Cambridge, graduated M.A. (1639), and taking orders, received a prebend of Salisbury and the rectory of Throington in Suffolk (1640). Ejected by the Parliamentary visitors, he became minister of St. Clement's, Eastcheap (1650), and there delivered a course of sermons published in 1658 under the title *Exposition of the Apostles' Creed*. At the Restoration he was created rector of St. Christopher's, London, D.D., by royal mandate, Prebendary of Ely, Archdeacon of Surrey, and Master of Jesus College, Cambridge. A year later P. obtained the Margaret professorship of divinity and sat in the Savoy Conference; in 1663 he became Master of Trinity College, and in 1673 was consecrated Bishop of Chester, where he died, 16th July 1686. P.'s great work on the Creed is calm, laborious, and acute; at once apologetic and polemical, it displays a profound knowledge of patristic theology; in Bentley's words, 'its very dross is gold.' The best edition is Dr. Burton's (6th ed. Oxf. Clarendon Press, 1870). Among his other writings are *Golden Remains of the Ever-Memorable Mr. John Hales of Eton* (1658); *Vindicia Epistoliarum S. Ignatii* (1672), and *Annales Cyprianici* (1684). P.'s *Opera Posthuma Chronologica* were edited by Dodwell (Lond. 1688), and his *Minor Theological Works* by Churton, with a memoir prefixed (2 vols. Oxf. 1844).

Peasant War (Ger. *Bauernkrieg*). The oppression to which the peasant class was subjected in the later middle ages by the privileged classes and the government many times and in various countries led to revolts marked by fearful cruelty on both sides; but the name P. W. is especially applied to the rebellion which broke out in 1525 in South Germany, and soon spread throughout all the neighbouring lands of Central Germany. Already in the beginning of the century revolutionary leagues had been formed among the peasantry. These were 'Der Rundschnh' in the Rhineland in 1502, and 'Der Bund des Armen Konrad' in Wurtemberg in 1514, whose chief objects were the abolition of villenage, the diminution of tithes and taxes, and the liberty of hunting. A misunderstanding of Luther's movement towards reform in the Church supplied fuel to the old discontent; men longed to be freed from ecclesiastical as well as civil oppression, and Luther's teachings on the freedom of the mind and the corruption of the Church were interpreted to the ignorant by fanatics like Karlstadt and Thomas Munzer (q.v.) to mean that all temporal and spiritual authority was henceforth at an end; that all men's lot should now be equal, and 'lords and castles no longer be endured.' The rising began at Kempten on New Year's Day, 1525, and quickly spread to Tirol, over the districts between Budensee and the Danube, and the lands on the Rhine and Main as far as Lothringen and Thuringen. The nobles could at first make little opposition, and many joined the rebel ranks by choice or by compulsion. On Easter Day they drew up twelve articles, moderate enough to win the approval of many of the cities. Luther saw ground for their claims, and urged the princes to treat with the people; but when success led them to frenzied cruelty, he raised his voice for order, and, condemning the revolt as unchristian, bade the rebels be cut down without mercy. The leaders of the peasants were Wendelin Hippler, organiser of the movement, Florian Geyer, Götz von Berlichingen, and Jäcklein Rohrbach, who 16th April 1525 stormed

Weinsberg, and massacred the Graf von Helfenstein and seventy knights. In May and June the peasants were gradually overpowered. The princes and nobles ranged themselves under the Landgraf Philipp of Hessen, who inflicted a crushing defeat at Frankenhäusen in Thuringen, 15th May 1525. Georg Truchsess von Waldburg had a like success (2d June) at Königshofen on the Tauber, and in the Allgäu the rebellion was speedily repressed by Georg Frundsberg. The struggle now ceased, but the peasants had henceforth to submit to greater cruelty and a harder yoke, the effects of which have not even yet wholly disappeared. For the history of the P. W. in detail see the works of Sartorius (1795), Oechsle (1830), Burckhardt (2 vols. 1832), Wachsmuth (1834), Bensen (1840), Zimmermann (2d ed. 3 vols. 1856-57), Cornelius (1862), and Schreiber (1864).

Pea-Stone. See PISOLITE.

Peat or Turf consists of vegetable matter in a more or less advanced condition of decay. P. forms large superficial bogs or hags (Turbaries), and is found widely disseminated throughout the world in positions and climates which favour its formation and accumulation. The principal condition necessary for the growth of P. is abundant moisture, for in the presence of a humid atmosphere the substance is found to accumulate at once in low-lying marshes, and on the sides and tops of hills, in the chilly highlands of Scotland and Sweden, and on the tropical plains of Bengal. The vegetation which goes to the formation of P. under these widely different conditions is quite dissimilar, but the result is the same. The plants which in Europe chiefly contribute to the formation of P. are species of *Sphagnum*, a genus of mosses. P. 'mosses' or bogs in mountainous tracts seldom exceed 4 feet in thickness, but in low grounds they vary exceedingly; and in Ireland they have been found 60 feet in thickness. P. also varies greatly in respect of the rate at which it tends to accumulate; and as an example of rapid growth, an instance is quoted in Ireland where a railway passes through a cutting in which a 15 feet P. deposit exists on a site covered with water 30 years previously. P. being a substance in course of formation presents all gradations of texture, specific gravity, and chemical composition from (speaking of European P.) a light, brown, matted mass of vegetable fibre up to a dense black compact homogeneous body, retaining scarcely any visible trace of vegetable structure. The chemical changes which P. undergoes in its elaboration are supposed to result in the liberation of marsh gas and carbonic acid, and in the formation of water by the union of hydrogen with the oxygen of the air. The result is that as compared with the composition of the *Sphagnum* from which the peaty matter is formed, P. shows a steady increase in its percentage of carbon, the oxygen present correspondingly decreases, while the hydrogen appears to follow no fixed law. The following figures show composition, excluding water and ash, of (1st) a light brown surface P., and (2d) a black compact old P. of high quality:—

	No. 1.	No. 2.
Carbon.....	52'38	61'02
Hydrogen	7'03	5'77
Oxygen, with nitrogen.....	40'59	33'21

In many countries where coal is not practically obtainable, P. is a valuable source of ordinary domestic fuel, and this is notably the case in Ireland, Holland, Westphalia, Bavaria, France, and Italy. In Ireland nearly 2,000,000 acres—about one-seventh of the area of the island—are covered with P., and the utilisation of the material is there a question of great importance, as much with the view of clearing land for profitable agriculture as for rendering the P. itself a source of profit. In the highlands and islands of Scotland P. is also the staple fuel of the inhabitants. The ordinary preparation of 'peats' for domestic use is a simple operation. The peats are cut generally in horizontal slices into pieces like large bricks by means of a specially constructed P. spade (called in Ireland a 'slane'), which has two cutting edges set at right angles to each other. As the peats are cut they are carried on barrows to a convenient spot and piled on edge for drying, a process which occupies a time varying with the nature of the weather. During the drying process they are once or twice turned, and with complete air-drying the P. retains from 10 to 26 per cent. of water. The presence of this amount of water, the general looseness and consequent bulkiness of P., and its friability are most serious obstacles to its usefulness as fuel, and it is really only available in the immediate

localities of its occurrence, where labour is cheap, and other sources of fuel difficult to obtain. Many efforts have been, and continue to be made, to render P. more generally serviceable, and to turn it to profitable industrial use, but hitherto little permanent success has attended these attempts. To improve it as fuel for metallurgical and other purposes systems of condensation and dessication have been introduced—the latest and most promising of which is the patent of Mr. Clayton. His process consists in first squeezing out as much water from the P. as possible by means of compression, after which the material is thoroughly masticated or pulped by means of revolving cutting blades, forcing screws, and discs acting within a cylinder. The effect of this apparatus is to thoroughly break up the cellular tissue of the P., and thus liberate the fixed moisture of the cellular tissue. The homogeneous mass is delivered in a continuous roll from the cylinder; it is cut into suitable lengths, and dried under cover, where it sets into an exceedingly hard compact mass. During the years 1873-74, when the price of coal rose abnormally, numerous companies were formed to work Clayton's patent, but these all collapsed on the fall in the price of coal. Charcoal is to some extent made from P., and used for sanitary purposes, as well as for smelting a high class of iron, such charcoal being entirely free from sulphur. Attempts on an extensive scale were made in Ireland about 1840 to distil paraffin oil, &c. (see PARAFFIN), from P., but these entirely failed of commercial success, and a later effort made by Sir James Matheson in the island of Lewis to establish a similar industry, although at first promising, also ended in failure.

Peaucellier Cell, a particular form of link work, so named after its discoverer—a French engineer, by which circular motion is transformed into true rectilinear motion. It consists of six

links, four of which form a rhombus. To two opposite joints of this rhombus two equal links are attached, and the other extremities of these are united at a common joint as shown in the figure. With centre D and radius DA or DC describe a circle. Then, since O A C are necessarily in the same straight line for every position of the linkage, the rectangle O A'. O C' = the rectangle O A. O C. But O A'. O C' = (O D - D A) (O D + D A) = a constant quantity, and therefore the product O A. O C is constant. From this it may be proved by simple geometry that if A is made to describe a circle which passes through O, the point C will describe a straight line perpendicular to the line joining O with the centre of the circle (A). If A describe any other circle, C will also describe a circle. It has other interesting properties, and has suggested a method for obtaining a force varying inversely as the square of the distance, and thus representing elliptic motion.

Pea-Weevil, a name given to certain beetles which destroy peas, beans, and other like crops. It is also given to the 'Pea-beetle' (q. v.) and its larvæ. The P.-W. is represented by such small beetles as the *Sitona lineata* and *S. crinita*, which do not attain a greater length than a quarter of an inch.

Pe'ba (*Tatusia peba* or *T. septemcinctus*), a species of Armadillo (q. v.) found in Guinea, Brazil, and Paraguay, and which may attain a length of thirty inches. The colour is a brownish-black. The flesh is tender and palatable.

Pebble (Old Eng. *pæbol*, allied to Dan. *pæble*, 'to flow with a bubbling sound'), a term used by lapidaries for an ornamental stone, chiefly of the chalcedonic group, but also including rock-crystal, from which the 'P. lenses' of spectacles are made; any water-rolled stone on a sea-beach or in a river-bed. The so-called 'Scotch pebbles' are banded agates, obtained chiefly in Perthshire. Agates, or pebbles proper, are wrought into a great variety of ornamental forms; the chief place of the manufacture is Oberstein in Germany, and the supplies of the raw materials are obtained in Uruguay and Brazil.

Peccary (*Dicotyles*), a genus of *Suidæ* or swine found in S. America. The tail is represented by a mere tubercle, and the hind feet are three-toed. A peculiar odoriferous gland exists in the back-region, and the upper canine teeth project downwards, and are not prominent. The incisor teeth number 4 above and 6 below, and there are 12 molars in each jaw. Of the P. the common collared P. or Tajaçu (*D. torquatus* or *Tajaçu*) is the

best known; it attains a length of 3 feet, and is of a brown colour, with a white stripe across the neck. The P. is noted for a habit of attacking other animals by congregating in immense numbers. It feeds on roots, grain, &c., and also on animal food. A second species is the white-lipped P. (*D. labialis*), which is larger and fiercer than the Common P. The colour in the white-lipped P. is brown, striped with grey. It has a white patch on both jaws.

Pe-chili. See CHILI.

Peck (a form of *pack*), a British measure of capacity containing 2 imperial gallons, and equal to the fourth part of a bushel. It is equivalent to 554.548 cubic inches.

Pe'cock, Reginald, born about 1395 in Wales, entered Oriel College, Oxford, of which he became fellow (1417). Ordained priest (1421), he received the mastership of Whittington College, along with the rectory of St. Michael-in-Riola (1437), was consecrated Bishop of St. Asaph (1444), and translated to the see of Chichester (1449). P. wrote in English several treatises against the Lollards, in which, however, he himself fell into heresy on the questions of infallibility, transubstantiation, and liberty of conscience. Accordingly, he was cited and condemned by the Archbishop of Canterbury (1457), and in spite of a recantation at Paul's Cross in the presence of 20,000 persons, was deprived of his see, and confined in the abbey of Thorney, Cambridgeshire, where he died about 1460. The best-known of P.'s writings, *Repressor of over much Blaming of the Clergy* (1449), has been edited, with an Introduction, by Mr. C. Babington (2 vols. Lond. 1860).

Pe'cos, a river of New Mexico and Texas, rises near Santa Fé, and after a generally S.S.E. course of 800 miles flows into the Rio Grande del Norte. In summer it is dry throughout the greater part of its length.

Pe'cten (Lat. 'a comb') or **Scall'op**, a genus of *Lamelli-branchiate* molluscs belonging to the *Ostracida* or oyster family, in which there are no hinge-teeth, and only a single adductor muscle. The mantle-lobes are separate throughout their whole extent. The shell is nearly circular, its apex being represented by a straight line. Externally, it is fluted with rounded longitudinal elevations. The common P. or scallop is the *P. varius*, the shells of which were worn of old in the hats of pilgrims. These shells swim through the water occasionally by the sudden closure of their valves, and the consequent ejection of water. Other species are the *P. islandicus*, *P. purpuratus*, *P. foliaceus*, *P. maximus*, &c.

Pe'ctinibranchia'ta, a division of *Gastropodous* molluscs, in which the gills or *branchie* are of comb-like shape. This division is not generally used in the modern classification of the group. Its members have been included under the sub-class *Branchifera*, and under various orders (*Siphonostomata* and *Holostomata*) of the latter group. The sexes are individualised. Tentacles and eyes are present, and the shell varies greatly in conformation. Whelks, cone-shells, volutes, periwinkles, &c., represent the group.

Peculiars, Court of. See ECCLESIASTICAL COURTS.

Peculium, in Roman law, was that property which a slave, or a *filius familias*, could acquire with his master's or father's consent. It might be acquired in war, or in exercise of public duty, or of the liberal arts, or derived from a stranger, or from the father.

Ped'al, a projecting piece of wood or metal attached to certain musical instruments to be pressed by the feet in order that particular effects may be produced. One P. in the piano-forte prolongs while the other softens the sound. The keys of the part of the organ containing the longest pipes are worked by pedals. The effect of the pedals of a harp is to sharpen or flatten the pitch of the strings.

Pedalia'cese is now placed as a sub-order of *Bignoniaceæ* (q. v.), from which it differs by having parietal placentæ and wingless seeds. There are about a dozen genera, e.g., *Sesamum* (q. v.), *Uncaria* (see GRAPPLE-PLANT), and *Martynia*, of which *M. fragrans*, a Mexican annual, is grown in gardens.

Ped'alpoint. See ORGANPOINT.

Pedes', Great, a river which is formed in N. Carolina, U.S., by the union of the Rocky and Yadkin rivers, and after

a S.S.E. course of about 350 miles, flows through S. Carolina into the Atlantic at Winyaw Bay. It is navigable to the falls at Cheraw, 250 miles from its mouth. Its chief tributary is the Little P., which also rises in N. Carolina.

Pedestal (Fr. *piédestal*, from Lat. *pes*, *pedis*, 'foot,' and Old Fr. *estal*, 'place,' 'posture,' cf. Old High Ger. *stal*), in architecture, the base of a column, statue, or other upright work, consisting of three parts; the base, the die, and the cornice.

Pedestrianism, taken in its most general meaning, is the art of walking, running, or otherwise engaging in foot exercise. With the development of artificial and more speedy means of transit, P., as a mode of travelling, has fallen greatly into disuse, and consequently in the present day the word is understood nearly always to mean what might be distinguished as *professional* P. Just as we have our professional cricketers, oarsmen, swimmers, boxers, &c., so have we our professional pedestrians. The most popular and most prevalent form of P. is foot-racing, which has always held a high position as a training exercise amongst nations where athletics were practised. (See **ATHLETICS**, **OLYMPIC GAMES**, &c.) For short races under half a mile speed is a great desideratum, but for long stretches of several miles speed is not of such importance as staying power. In 1861 various long races were held between Deerfoot, a Seneca Indian, and English and other champions. In these competitions the Indian showed to advantage, running 12 miles in 65 minutes 5 seconds. He was beaten, however, in 1863 by White, who ran 10 miles in 52 minutes 14 seconds. In walking feats we have another phase of P., which within the last few years has excited considerable attention. The famous journeys of Powel, Barclay, and Manks have been excelled by the pedestrian triumphs of Weston, O'Leary, and Gale. In 1788 Richard Powel walked from London to York and back, a total distance of 450 miles in 140 hours. Captain Barclay, in 1809, undertook to walk 1000 miles in 1000 successive hours, and won in accomplishing his task a large wager. This feat was repeated with similar success by Richard Manks, a native of Warwickshire, in 1850. In 1876 the feats of E. P. Weston, the American pedestrian, attracted general attention. In 48 hours (on February 15 to 17) he accomplished 180 miles 668 yards—a distance never before covered in the same time—and (starting 23d December) 460 miles in 33 minutes less than 144 hours.

Pedetes, a genus of *Rodent* quadrupeds belonging to the Jerboa family, represented by the spring haas or jumping hare (*Helayms* or *P. Capensis*) of S. Africa. The species just mentioned attains a length of 1½ feet. Its hind legs are much longer than the fore-limbs; and its hinder feet have four toes, while its fore-feet have five. The tail is very long. The colour of the animal is a warm brown. The P. will leap from 20 to 30 feet at a bound.

Pedicellariæ are certain peculiar bodies of minute size found adhering to the outer surface of such Echinoderms as sea-urchins, star-fishes, and the like. They consist essentially of a stalk, at the upper extremity of which two or three jaws are formed, which are continually in motion. The P. are allied to the *Avicularia* or 'birds-head processes,' seen on the exterior of *Polyzoa* (q.v.). Their exact nature is still a matter of doubt.

Pedicellina, a genus of 'social' *Polyzoa* (q.v.), somewhat resembling moss, and consisting of a series of organisms united together by root-like processes. They are found in the sea, are of soft consistence, and the tentacles are arranged in a horse-shoe or crescentic shape. *P. echinata* is a familiar species.

Pedicularis (from the pedicle being supposed to encourage lice in sheep, hence the English name of louse-wort) is a genus of about 100 species of *Scrophulariaceæ*, natives of N. temperate regions. Two species are common in Britain, namely, *P. palustris*, an annual plant found in bogs and marshes, and *P. sylvatica*, a perennial mixing in the turf of damp pastures and heaths; *P. scepterum-Carolinum*, a yellow-flowered species of N. Europe, was so named by Rudbeck from its sceptre-like habit of growth, and in honour of Karl, King of Sweden. None of the species appear to be in cultivation or to possess special uses.

Pediculus. See **LOUSE**.

Pedigrees (variously derived from *pedes graduum*, *par degrés*, or *piéd-de-grue*, 'crane's foot,' alluding to the shape),

genealogical tables showing the origin of a family and the relationship of its members one to another, were formerly often drawn in the shape of a tree springing from the founder's breast, like the familiar Jesse windows of English churches. The method, however, now generally adopted gives them thus:—
John Noakes — Mary, dau. of Thomas Styles.

Edward

Charles, d. s. p.

Here *dau.* signifies 'daughter,' and *d. s. p.* (*sine prole*), 'died without offspring'; other frequent contractions being, for 'son,' *s.* for 'heir,' *v. p.* (*vita patria*), for 'in his father's lifetime,' &c. The importance of authentic P. in questions of inheritance, alike in law and history, is easily intelligible, and need not be dwelt on here. But the question why men, apart from any practical considerations, should set a high value on long-traced P., and whether that value is reasonable, deserves consideration. The question is really one of hereditary genius. If a pedigree shows that a man's forefathers possessed a higher than the ordinary culture, that his family has produced great warriors, statesmen, or ecclesiastics, then, granting the doctrine of hereditary genius, that man may justly prize his heritage. If, on the other hand, a Newcome's pedigree begins with a Norman barber, whose sons kept on the business still, its possessor has no more cause to vaunt himself upon its length than an ass on the extension of his ears. But, as a rule, long P. imply gentleness of birth, and gentleness of birth as high culture as the times admitted of. The man who sneers at 'pride of birth' will very likely be the first to boast that his horse's sire won the Derby, or that his greyhound came of the same stock as 'Master Magrath.' The merits of the question are quaintly brought out by Dame Juliana Berners, who in the *Book of St. Albans* (15th c.) speaks of the murderer Cain and all his race as 'churls,' but of Shem's 'gentlemanly' line, culminating in Mary, 'princess of coat-armour.' Nowhere were P. so important as in France, where up to the Revolution no one could be presented at Versailles unless he could prove 400 years of gentility, and where Chateaubriand had to send in his pedigree for examination before he was allowed to hunt with the king. Some of our greatest nobles would fare but badly did such a test precede a modern drawing room. It is true that Grimaldi, in his *Origines Genealogicæ*, analysed the peerage of 1828, and discovered that of 249 noblemen 35 'laid claim' to having traced their descent beyond the Conquest, 110 prior to 1300, and 43 prior to 1500. But a better authority, Sir Harris Nicolas, fixing as his standard of pretension the having been of baronial or knightly rank in the reign of Elizabeth, found that only one-third of the body were entitled to it. The Wars of the Roses played tremendous havoc with our ancient houses, and Dugdale says that out of the 270 families treated of in the first volume of his *Baronage* (1675) scarce eight continued to his day. Indeed, many modern P. are almost as ridiculous as Chesterfield's, commencing 'Adam de Stanhope = Eve de Stanhope,' or the Welshman's, half way down which came the creation of the world. Yet, if Wardour Street genealogies are contemptible, a genuine pedigree compiled from registers and historic documents is interesting and instructive. The man who knows that his grandfather trailed a pike at Naseby or lifted a cow from a Southern lord, will read with keener pleasure Carlyle's *Cromwell*, or Scott's *Minstrelsy of the Scottish Border*, than he who thanks God that he knows not who was his grandfather. 'Happy,' says Jean Paul, 'is the man who can trace his lineage ancestor by ancestor, and cover hoary time with a green mantle of youth;' and we see Franklin, the great liberal, going down to the out-of-the-way English village from which his yeoman ancestry was sprung. See **GENEALOGY**; C. Roberts, *Calendarium Genealogicum* (2 vols. Lond. 1865); and G. Burnett, *Popular Genealogist, or the Art of Pedigree-Making* (Edinb. 1865).

Pediment (Ital. *frontispizio*) is a term used in classical architecture to denote the triangular space formed by the termination of the roof above the portico. It consists of three parts, the *tympa-num*, or plane face, which is often decorated with sculpture, the *cornice*, which skirts it, and the *acroteria*, small pedestals for statues at the feet and apex of the P.

Pédipalpi or **Arthrogas'tra**, an order of higher *Arachnida* (q.v.), represented by the scorpions, &c. In this group the *maxillary palpi*, or organs of touch appended to the lesser jaws,

are large, and are converted into nipping-claws or *chela* similar to those seen in the lobster, &c. They are frequently mistaken for the first pair of legs. The abdomen is segmented, and consists of twelve joints. The mandibles are also converted into *chela*. The tail is terminated by a poison-fang and poison-gland.

Pedlars. See **HAWKERS AND PEDLARS.**

Pedometer (Gr. 'a foot-measurer'), an instrument for recording the distance travelled by a pedestrian or horseman. Payne's P., patented 1831, is generally used in Great Britain on account of its simplicity and compactness. It closely resembles a watch in appearance. The motion of a lever or pendulum, which vibrates at each pace or step of the wearer, is transmitted through a train of wheels to an index placed over a figured dial. This P. requires to be regulated to the person using it, if it does not correctly record a *known* distance. See **ODOMETER.**

Pedro I., Don, commonly called **The Cruel**, King of Castile and Leon, 1350-69, son of King Alfonso XI. and Maria, daughter of King Alfonso IV. of Portugal, was born at Burgos, 30th August 1334. His education was neglected, and he early became the slave of violent passions and an unbridled will. He had already married privately Donna Maria de Padilla, when in 1353 he was persuaded by his mother to marry Blanche, daughter of Pierre de Bourbon, and sister of the Queen of France. His elevation of Padilla's relations to the highest offices estranged his early favourite, Don Juan de Albuquerque, who, fearing for his life, fled to Portugal. P. now imprisoned Blanche, procured a divorce from an assembly of bishops, and married Donna Juana Fernandez, widow of Don Diego de Haro, and sister of Don Fernando Perez de Castro. In a few months she also was divorced, and soon after there broke out an insurrection, headed by Enrique de Trastamara, an illegitimate son of P.'s father by Leonora de Guzman. Aided by the influence of the Pope, it proved too powerful for P., who consented to take back Blanche, his former queen, and mitigate his oppressive rule. In 1361 Blanche was poisoned at Xeres, and Donna de Padilla having died soon afterwards, P. obtained from the Cortes a recognition of the legitimacy of her children. Enrique, joined by the Kings of Aragon and Navarre, and the redoubtable Bertrand du Guesclin, entered Castile in 1366. P. fled from Burgos to Seville, and soon Enrique was acknowledged king throughout Castile. P. took refuge in Portugal, whence he passed to Coruña, where he embarked for Bayonne in 1366. Edward the Black Prince, who had formed an alliance with P. in 1363, marched from Gascony in 1367 through Roncesvalles and the kingdom of Navarre, and entered Castile at the head of 30,000 men. On the 3d April he completely defeated Enrique of Najera on the Ebro. The lordship of Biscay, which P. had promised to his ally as a reward, he finally refused, and the English prince leaving the country in disgust, P. reverted to his former cruelty. He was assassinated 23d March 1369, at the town of Montiel, by Enrique, who was immediately proclaimed King of Castile.

Pedro I. de Alcântara, Dom, Emperor of Brazil and King of Portugal, second son of João VI., King of Portugal, was born at Lisbon, 12th October 1798. He was carried by his parents to Brazil (1807) in their flight thither on the invasion of their country by Napoleon; and after his father was recalled (1820) to Portugal by the Cortes, P. became (22d April 1821) regent of Brazil, which had been declared a kingdom in 1815. Having proclaimed the independence of the country on the 7th September 1822, on the 1st December he was crowned 'Constitutional Emperor.' Though he gained general favour by granting a liberal constitution, he had to repress several local insurrections before his rule was firmly established, and not till 1825 was the independence of Brazil recognised by Portugal. On his father's death, P. succeeded (10th March 1826) to the Portuguese crown as P. IV., but the Brazilian jealousy of a connection with Portugal induced him (2d May) to resign that kingdom to his daughter, Donna Maria de Gloria, reserving to himself the regency during her minority. P.'s brother, Dom Miguel, whom he had appointed regent in February 1828, seized the crown on the 25th of the following June. An insurrection broke out (6th April 1831), and P. abdicated (7th April) the throne of Brazil in favour of his son, Dom P. II. He imme-

diately embarked for France, and in February, with a small army under General Saldanha, began the struggle against his usurping brother, which ended in Dom Miguel being reduced to yield the crown to Donna Maria (23d September, 1833). P. now set himself vigorously to work for the restoration of order, and strengthened the government by a close alliance with England and France. Again appointed regent by the Cortes, 23d August 1834, he died at Lisbon on the 24th of September following.—**P. II. de Alcântara, Dom,** Emperor of Brazil, son of the above, was born at Rio de Janeiro, 2d December 1825. He ascended the throne (7th April 1831) on the abdication of his father, and ruled at first (till September 1835) under a triumvirate government, then (till September 1837) under the regency of Diego Antonio Feijo, and afterwards of Pedro Araujo de Lima. In July 1840 he was declared of age by the Chamber of Deputies, and on the 23d of that month undertook the government. He was crowned on the 18th July 1841, and on September 4, 1843, married Theresa Christina Maria (born 14th March 1822), daughter of Francisco I., King of the Two Sicilies. From this marriage sprang two sons, who died in infancy, and two daughters, (1) Isabel, the Crown-Princess and heiress-presumptive to the throne (born 29th July 1846, and married 15th October 1864 to Prince Louis of Orléans, Comte d'Eu); and (2) Leopoldina (born July 13, 1847), married December 15, 1864, to Prince August of Sachsen-Koburg-Gotha, and died February 7, 1871. The early years of P.'s government were much disturbed by popular revolts, and after these by foreign wars against the dictator Rozas of Buenos-Ayres (1851-52), the Republic of Uruguay (1854-55), and again 1864-65), and, finally, President Lopez of Paraguay (1865). Since securing peace on a permanent footing P. has devoted his reign to the constitutional government and internal improvement of Brazil (q. v.), and is one of the most enlightened and popular monarchs of his time.—**P. V. de Alcântara, Dom,** King of Portugal, son of Queen Maria II. de Gloria, by Ferdinand, Duke of Sachsen-Koburg-Gotha-Kohary, was born at Lisbon, 16th September 1837. On the 15th November 1853, he ascended the throne while yet a minor, and on the 16th September 1855 received full kingly power. In 1858 he married the Princess Stephanie Frederika Wilhelmine Antonie of Hohenzollern-Sigmaringen. He died 11th November 1861. See **PORTUGAL**, and his Biography by Schellhorn (1866).

Peduncle (in Zoology) applied to the fleshy, muscular stalk of such fixed animals as the Barnacle (q. v.), or to the stalks which support the compound eyes of such crustaceans as lobsters, &c.—In Botany, see **FLOWER** and **INFLORESCENCE.**

Peebles, an ancient royal burgh of Scotland, and capital of Peeblesshire, is situated on the N. bank of the Tweed, 27 miles S. of Edinburgh, and 7 miles N.W. of Innerleithen by rail. It lies amid hills, and the exquisite beauty of its surroundings, as well as the purity of the air and the excellent fishing (salmon and trout) to be had in its neighbourhood, make it a favourite resort for summer visitors. At Soonhope, Venlaw, within a few minutes' walk of the P. railway station, a hydro-pathic establishment was commenced (1878) which must increase the attractions of one of the most romantic localities in Scotland. The town contains six churches, and a public library of 15,000 volumes, which forms part of the 'Chambers' Institution'—a gift to the town by William Chambers, the eminent publisher, who is a native of the place. Within recent years the woollen manufactures carried on here and at Innerleithen have become important. In 1877-78 the annual value of real property was £8685, exclusive of railways. Pop. (1871) 2631. In early times P. was a seat of the Scottish kings, and had a royal castle and chapel. A church and monastery for the Trinity Friars was built here in 1260 by Alexander III., and in 1357 the town was made a royal burgh by David II. It is still governed by a provost and town council, under a charter granted by James VI. P. has a choice place in Scottish poesy as the scene of that sprightly and humorous sketch of rustic pastimes known as *Peebles to the Play*, variously ascribed to James I. and James V. of Scotland.

Peeblesshire, an inland county in the S.E. of Scotland, is bounded N. and N.E. by Edinburghshire, E. by Berwickshire, S.E. by Selkirkshire, S.W. by Dumfriesshire, and W. by Lanarkshire. Area, 227,869 acres; pop. (1871) 12,330. The surface is hilly,

the chief peaks being the Hart Fells (2790), Dollar Law (2790), and Broad Law (2740), while there are many others above 2000 feet. The principal streams are the Tweed, and its tributaries the Eddleston, Leithen, Quair, Manor, and Lye. The chief geological formations are the Old Red Sandstone and the Carboniferous. The soil of the valleys is fertile, and is excellently cultivated, while the high districts afford good pasture. In 1876 there were 10,979 acres under corn crops, 6599 under green crop, 13,675 under clover and grasses under rotation, and 10,480 of permanent pasture. There were also 1113 horses, 6495 cattle, and 196,720 sheep. The total valued rent for 1877-78 was £125,820, exclusive of railways, which were valued at £31,099. The principal mineral obtained is lead ore, and there are quarries of slate, limestone, and freestone. The manufactures of P. are almost entirely confined to the towns of Peebles and Innerleithen. The chief villages are Linton, Carlisle, and Skirling. See Chambers's *History of P.* (Edinb. 1864).

Peel, a small seaport of the Isle of Man, on the western coast, 10½ miles N.N.W. of Douglas, has a harbour formed by a jetty 1200 feet long, and is the chief station of the island herring fishery. On an islet 100 yards N. of the town stand the ruins of St. Germain's cathedral (1245), and of the castle of the Earls of Derby, immortalised in Scott's *Peveril of the Peak*. Pop. (1871) 3513.

Peel, Sir Robert, an English manufacturer, was born near Lancaster, 25th April 1750. Entering the cotton-spinning trade on the back of Arkwright's invention, he rapidly made a fortune, purchased estates in different counties of England, was a large contributor to the 'Loyalty Loans,' and an ardent volunteer, became a baronet in 1800, represented Tamworth in Parliament for many years, and before he died employed at his works as many as 15,000 workmen. He died at Drayton Manor, Staffordshire, 3d May 1830.—**Sir Robert P.,** son of the preceding, was born near Bury, Lancashire, 5th February 1788. He was educated at Harrow and Christ Church, Oxford, where he took the degree of B.A. in 1808 with almost unprecedented distinction. In 1809, he was returned to Parliament in the Tory interest for Cashel, and immediately applied himself vigorously to getting up the work of the House. He became Under Secretary for the Colonies in 1811, and Secretary for Ireland in 1812. The latter post he held for six years, earning the cordial hatred of the Irish by his police organisation and his relentless bias against the Catholics. In 1817 P. was returned for the University of Oxford, and his parliamentary reputation began, meanwhile, to increase as his aptitude for finance became more and more apparent. In 1819 he was appointed chairman of the Bank Committee, and brought in a bill for limiting the circulation of paper money and resuming a system of cash payments. In 1822 he took the place of Lord Sidmouth at the Home Office and in an administration which included the semi-liberal Canning was distinguished for his defence of the strictest canons of Toryism. To fiscal matters generally, and the question of the currency in particular, he continued to devote much attention. In 1827 he retired from the Cabinet over which Canning then presided, though on many questions his opinions were ripening slowly towards Liberalism. Returning to place with the Duke of Wellington, his altered political attitude was now shown in respect to the Corporation and Test Acts. In March 1829 he astounded his party and alienated his friends by introducing an Emancipation Bill for the Catholics. It was supported by the Whigs and carried through by a triumphant majority; but P. paid the penalty of his act by forfeiting his seat at Oxford. In 1830 he succeeded to his father's baronetcy and estates, and in the same year, while the question of reform began to be pressed, the Ministry fell. The Reform Bill of 1831 seemed to him far too great a stride in the direction of democracy, and he opposed it all through its career. Under the new Act he was returned to Parliament for Tamworth (1833), on which occasion he made his famous enunciation of principles, explaining that he was the blind partisan of no system, but that under changed circumstances he abandoned old maxims and measures in order to bring himself into harmony with the times. He became Prime Minister towards the end of 1834, but being defeated in division on three separate occasions he retired (April 1835). While in opposition, though he continued to vigorously oppose the Liberal Ministry, more than once he was found in the same lobby. After the general election of 1841 P. was

sailed to form a cabinet, the Conservative party in the country having been increased by the desire to have the fiscal difficulties, which had accumulated under the Liberals placed in the hands of P. The corn-law agitation had also begun, and as Lord J. Russell only promised the half measure of a moderate fixed duty upon corn, while P. declared his preference for a sliding scale, the latter received strong Conservative support, and the former merely 'the cold and languid preference of the radical and free-trade parties.' In February 1842 he brought forward his proposal for dealing with the corn laws amid much excitement. The sliding scale was maintained and improved, but the duties were lowered and the artifices attendant on the old scale rendered impossible. His measure was described by Macaulay as one 'which pleases nobody, which nobody asks for, and which nobody thanks him for.' The same year he set himself to make good the financial deficiency left by his predecessors, and even to obtain a surplus. He accomplished it by the imposition of an income and property tax, acquiescence in which was purchased by the reduction or abolition of burdensome taxes on 750 out of 1200 articles subject to customs duties. By 1846 P.'s opinions on the corn laws had undergone an entire change, and at the opening of the session, amidst the general vituperation of his party, he declared himself a convert to free trade. The attack made upon him by Disraeli was that statesman's first step to acknowledged power. In June P. retired from office, and won the esteem of all impartial observers by his moderation under attack, his indifference to power, and his anxiety to give honour to whom it was due in connection with free trade. Practically he was now a Whig, and often voted with that party. On June 29, 1850, he was thrown from his horse while riding in Hyde Park, and three days later died of the injuries sustained. P. was a proud, shy man, a conscientious thinker, true to his convictions, though slow in forming them, and an easy and even voluble speaker. 'Of all the men I ever knew,' said the Duke of Wellington, 'he had the greatest regard for truth.' He was an Englishman of the highest character, if not of the highest genius, and his memory is still profoundly revered by his countrymen. See Lord Dalling and Bulwer, *Life of Sir Robert P.* (Lond. 1874), and Doubleday, *Political Life of Sir Robert P.* (Lond. 2 vols. 1856). See *Memoirs by Sir Robert P.*, published by Earl Stanhope and the Right Hon. Edward Cardwell (2 vols. Lond. 1857).—**William Yates P.,** brother of the preceding, born 3d August, 1789, at Bury, educated at Cambridge, studied law and became a barrister, was returned to Parliament in 1817, and sat till 1852. He served as an Under-Secretary of State (1828), and Lord of the Treasury (1834-35). His death occurred in June 1858.—**Jonathan P.,** brother of the preceding, born 17th October 1799, entered the army and rose to the rank of major-general. From 1841 to 1846 he acted as inspector-general of artillery, and during 1858-59 he was War Minister under Lord Derby. In 1866 he was called to the same post, but retired March 1867, owing to a difference in connection with the Reform Bill.—**The Right Hon. Sir Lawrence P.,** cousin of the preceding, was born in 1799, educated at Cambridge, called to the bar of the Middle Temple, filled the post of Advocate-General at Calcutta, became Chief-Justice of the Supreme Court, and (1855) Vice-President of the Legislative Council at Madras. In 1871 he became one of the paid members of the Judicial Committee of the Privy Council.—**The Right Hon. Sir Robert P., G.C.B., M.P.,** eldest son of the late Sir R. P., was born May 4, 1822, educated at Harrow and Christ Church, Oxford, became attaché to the British Embassy at Madrid from June 1844 till May 1846, when he became secretary to the British Legation in Switzerland, and was appointed chargé d'affaires, a post from which he retired in 1850. In that year he succeeded to his father's fortune and title, and was returned for Tamworth as a Liberal. From 1855 to 1857 he acted as a Lord of the Admiralty, and from 1861 to 1865 as Chief Secretary for Ireland. He was present at the coronation of Alexander II. in 1865 on a special mission, and in the same year became a Privy Councillor. P. is a lively but rather diffuse speaker; on Irish and international subjects, however, he is always listened to with respect. During the debate upon the war vote (February 1878) he both spoke and voted with the Conservative party.

Peele, George, an English dramatist and poet, belonged to a good Devonshire family. Born, according to Dyce, about 1552-53, he studied at Broadgates Hall (now Pembroke Col-

lege), Oxford, took his degree of B.A. (1577), and his M.A. (1579). He married a lady with some property, and in 1581 went to London. Before he left the university he had (says Wood) a reputation as a poet, and executed a (lost) translation of the *Iphigenia* of Euripides. He had also a hand in 'providing' the comedy and tragedy acted on the occasion of the visit paid to Oxford (June 1583) by the Polish Prince Palatine. In London, P. was chiefly a playwright, but sometimes an actor. In 1584 he published anonymously *The Araynement of Paris: a Pastorall, presented before the Queenes Maiestie by the Children of her Chapell*. It is in five acts, and the dialogue is extremely simple. The verse is partly rhymed and partly blank. Next year P. devised a Lord Mayor's pageant. From 1589 to his death, which happened before 1598, he wrote for various dramatic companies, Pembroke's, Lord Strange's, the Chamberlain's, &c. His best-known pieces are the *Tale of Troy*, a poem in heroic couplets; the *Old Wives' Tale*, 'a sort of child's story told with a poet's playfulness'; *Edward I.*, in passages of which we hear (but in more turgid style) the patriotic ring of Shakespeare's historical dramas; and the *Love of King David and Fair Bathsheba*, according to Campbell, 'the earliest fountain of pathos and harmony that can be traced in our dramatic poetry.' P. has a bright scholarlike fancy, a sweet musical style, and a fine vein of tender feeling. His works have been carefully edited by the Rev. Alexander Dyce (Lond. 3 vols. 1829-39).

Peel Towers, the Border fortresses of the old mossroopers, familiar to every reader of Scott's *Monastery* or *Black Dwarf*. Their name is identical with the 'pile or castelet' of Langland, Fabian, and Leland, a word connected with the Lat. *pila*, the Old Eng. *pill* ('stake'), and the Celt. *pill* ('a castle').

Pes-pul, or **Pi-pal** (*Ficus Religiosa*), a common Indian tree held sacred by both Hindus and Buddhists. The Hindus regard it as occupied by the god Brahma, and accordingly invest it with the Brahminical cord. Under the name of the Bo-tree, or tree of wisdom, it holds a position among Buddhists similar to that of the Cross among Christians, for it was while sitting under this tree that Gautama became 'enlightened.' An offshoot of the original tree is still shown near Gaya in Behar; and another branch planted at Anuradhapura in Ceylon can be historically proved to be now (1878) 2123 years old—the most ancient tree in the world. See Sir E. Tennent's *Ceylon*, vol. ii. (1860).

Peer (*ptr*), a word of Persian origin, used throughout India for a holy man among the Mohammedans. It is especially applied to a deceased saint whose tomb has become a place of pilgrimage, or to the chief of a body of monks or mendicants.

Peers (Fr. *pairs*, Lat. *pares*, 'equals') is the name given to the nobility of Great Britain and Ireland to mark their political equality. Whatever grades of honour or distinction may exist in the peerage, its members are on a political level as a separate estate of the realm. Dukes, Marquises, Earls, Viscounts, and Barons are 'equals,' and vote as such in the House of Lords.

Peewit. See LAFWING.

Peganum is a monotypic genus of *Zygophyllaceae*, interesting botanically from possessing certain characteristics of *Rutaceae*. The species *P. Harmala* is common in S. Europe and Asia Minor, and is a powerfully-smelling herb, with alternate, entire, or divided stipular leaves, white axillary flowers, and a capsular fruit opening by three valves. In Turkey the seeds are used as a vermifuge, and also, it is said, as a spice and for dyeing red.

Pegasse, a variety or species of Ox (q. v.) occurring in W. Africa. It is the *Bos pegasus* of naturalists, and has a short head, a wide forehead, and long and spreading horns. The ears are also long and drooping. Both legs and tail are long, and the neck is maned.

Pegasus, a genus of Teleostean fishes, found in warm seas, and including species known popularly as 'sea-dragons.' They belong to the sub-order *Lophobranchii*, and are thus near neighbours of the *Hippocampi* or 'sea-horses.' In the family *Pegasida*, the breast is broad, and the pectoral or breast-fins very long and supported on spiny rays. The mouth is placed on the under surface of the snout. The 'sea-dragon' is the *P. draco*, and the 'Pegasus' or *P. natans* is a second species.

Pegasus, in Greek mythology, is the name of the winged horse which sprang from the Gorgon Medusa, along with the

god Chrysaor, when her head was struck off by Perseus. The name P. was given him because he first appeared near the sources (*pege*) of Oceanus. He is said to have mounted to heaven, and dwelt in the palace of Zeus, whom he served as the bearer of fire and thunder. With the assistance of P., Belerophon (q. v.) slew the Chimæra, and conquered (according to Pindar) the Amazons and Solymi; but on attempting to ascend to heaven on his back, he became giddy and fell to the earth, while P. pursued his flight alone to the abode of the immortals. According to another legend, when Mount Helicon, hearing the singing of the Muses, began to rise heavenward with delight, P. stopped its rising by giving it a kick, and from the hoof-mark there arose Hippocrene, the fountain of the Muses, and the source of inspiration. On account of this P. has been represented in modern writings as the horse of the Muses, a character in which he was unknown to the ancients.

Pegu, a province of British Burmah, lying between Arracan and Tennasserim, and occupying the entire valley of the Irrawaddy river from Prome downwards. Area, 27,390 sq. miles. Pop. (1872) 1,662,058. It contains the capital, Rangoon, and the port Bassein. It also includes the rice swamps, and the navigation of the Irrawaddy, and forms the most populous and wealthy portion of Burmah. The inhabitants are now mostly composed of Mughs or Burmese proper, who are Buddhists, and the hill tribe of Karens (q. v.), of whom many have been converted to Christianity. The native Peguese, called also Talaings or Muns, have been either exterminated by the Burmese kings or driven S. into Tennasserim; and their capital of P., on the river of the same name, about 70 miles N. of the present city of Rangoon, has now almost disappeared. In the 16th c. the Peguese founded a great kingdom; their capital was first at Tungu (q. v.), and afterwards at P. city, of which gorgeous descriptions are given by early travellers, and which is said once to have numbered 140,000 inhabitants. After numerous and sanguinary wars with the Burmese proper of Ava, the Peguese were exterminated rather than subdued in 1755. During the first Burmese war of 1823-26 P. was entirely overrun by the British force, and was the scene of many sharp encounters and much loss by sickness. It was not annexed until the conclusion of the second war of 1852, when Independent Burmah was entirely cut off from the seaboard. The horses of Burmah are generally known as P. ponies.

Pehlevi ('language of heroes'), a vernacular dialect of the primitive Persian or Iranian language, used under the dynasty of the Sassanids (235-640 A.D.), who revived the national religion of fire-worship. The grammatical basis of the language is the ancient Zend, considerably modified by the introduction of Semitic words. The alphabet also is Semitic, and consists of only thirteen distinct letters. The sacred books of the Parsees (q. v.) are written in P., the philological study of which has recently made much progress at Bombay. See Dastur Jamaspji's *Dictionary of P.* (vol. i. Lond. 1877).

Pei-ho, an important river in the N. of China, is formed 50 miles from its mouth by the confluence of the When-ho, Hui-ho, Jan-ho, and Wei-ho, which together water the province of Chi-li and part of Shan-si. The main stream, When-ho, which rises in Shan-si, among the mountains of the frontier, has a course of 450 miles, and forms the highway to Peking. Wei-ho is connected by the Grand Canal with the Hoang-ho.

Peine Forte et Dure (the 'strong and hard pain') is a kind of torture formerly inflicted on those who stood mute or refused to plead when put on trial. The prisoner was put into a low dark chamber, laid on his back, naked, on the floor. As great a weight of iron as he could endure was then laid upon him, and in this situation he was fed with nothing but bread and water till he died, or until his obstinacy was overcome. It appears by a record of 31 Edward III. that a prisoner lived forty days under this punishment. The motive of any one so suffering rather than answer was probably to escape the forfeiture of lands which under former law followed a conviction for felony. By 7 and 8 Geo. IV. c. 28, if any person arraigned of any crime remain mute, or will not answer directly to the charge against him, the court may order a plea of 'Not guilty' to be entered, when the trial must proceed as if the accused had actually so pleaded. P. F. et D. is said to have been inflicted in England as late as 1741. A curious and vivid account of the case of Margaret Clitheroe,

the stepdaughter of the Mayor of York, who actually suffered death from 'the strong and hard pain,' 25th March 1886, is recorded in *Morris's Troubles of our Catholic Forefathers* (1877).

Pelpus, a lake of Russia, between the governments of St. Petersburg, Pskov, Livonia, and Esthonia, connected at the S.E. with Lake Pskov by a channel 16 miles long, and from 1½ to 4½ miles wide. It is 52 miles long and 4½ broad; its depth is 45 feet, and its area 1408 sq. miles. Fed by the Embach and the Velikaya, it empties itself into the Gulf of Finland by the Narova, 44 miles long. The banks of P. are flat, sandy, and largely covered with fir trees, and the lake abounds with fish. It has four islands, of which Narka is the largest: the only town upon its banks is Sdov.

Peish'wah (*Pashwa*, 'over-lord'), the title of the hereditary prime minister of the Rajahs of Sattara, the descendants of Sivaji the Great, the founder of the Mahratta power in W. India. The first P. was Balaji Vishwanath, a Brahmin by caste, who made himself 'Mayor of the Palace' in 1712. For nearly a century his descendants guided the policy of the Mahratta confederation in its antagonism to the Mohammedans. They fixed their capital at Poonah, the central home of the nation, about 1740; and are said to have directed at one time an army of 100,000 horsemen, with an annual revenue of seven millions sterling. The seventh and last P. was Baji Rao, who succeeded in 1796. To escape from the rivalry of the two great military chiefs of the Mahrattas, Scindiah and Holkar, he put himself under the protection of the British by the treaty of Bassein in 1803. This led to the war in which Sir Arthur Wellesley and Lord Lake completely defeated the Mahratta armies. In 1811 Mr. Elphinstone (q. v.) was appointed Resident at Poonah, and his special duty was to frustrate Mahratta intrigues. In 1816 the P. made a treacherous attack upon the Residency, but he was defeated at the battle of Kirki. He ultimately surrendered to Sir John Malcolm, who guaranteed to him a pension of £80,000 a year. His territories were annexed to the Bombay Presidency, and Bithur near Cawnpore was assigned as his residence. Here he lived till 1853, having adopted as his heir the infamous Nana Sahib (q. v.). The latter was undoubtedly regarded throughout India as the hereditary P.; and the refusal of the British Government to continue to him any portion of his adoptive father's pension, is supposed to have had something to do with the outbreak of the Mutiny in 1857. See Grant Duff's *History of the Mahrattas* (Lond. 1826); Sir John Kaye's *History of the Sepoy War*, vol. i.; *Selection from the Wellesley Despatches* (Oxf. Clar. Press. 1877).

Peisistratos (Lat. *Pisistratus*), a famous Athenian 'tyrant,' son of Hippocrates, was named after P., Nestor's youngest son. The mother of P.—her name is unknown—was cousin-german to the mother of Solon. The date of P.'s birth cannot be fixed with certainty. The year 612 B.C. seems a probable date, and certainly he could not have been born much later. His personal beauty and mental culture were great. Carefully educated, of winning manners, high-souled and generous, few among the Athenians could compare with him. His craving for power and supremacy, however, led him to condescend to acts of dissimulation utterly at variance with his generally mild and beneficent character. The relationship of P. to Solon led to a close and intimate friendship between them; and one of the first public acts of the former was by his eloquence to aid his kinsman in the war against the Megarians. In this expedition P. distinguished himself by military skill and bravery. Meanwhile the position of parties at Athens became unsettled. The old hostilities of the rival factions—the *Plain*, the *Coast*, and the *Highlands*—checked for a time by Solon's prudent legislation, broke out afresh. The party of the Plain comprised the landed proprietors; that of the Coast the wealthy middle class; that of the Highlands those whose political freedom and political equality were, from their more contracted circumstances, ill defined and hardly recognised. Lycurgus became the champion of the first party; Megacles, the Alkmaeonid, of the second; while P., seeing that this was a favourable opportunity for advancing his ambitious aims, threw in his lot with the Highlanders. He appeared as the patron and liberal benefactor of the poor, threw open his gardens to the use of the citizens indiscriminately, and dispensed charity in the public streets. The best of the citizens were hoodwinked, and hailed in him, if not a deliverer from oppression, at least the friend of

moderation and clemency. Solon at once saw through his kinsman's schemes. He remonstrated with P., but in vain, warned the people of their danger, and endeavoured by speeches and poems to rouse them from their listless inactivity, but to no purpose. Even the members of the Senate were disposed to believe in P., and to declare Solon mad. The decisive moment arrived. P. appeared in the Agora with his body and his mules wounded, pretending that he had been well-nigh assassinated on account of his patriotic action. Indignation ran high in the city, the assembly was convened, and on the motion of Ariston a bodyguard of fifty citizens was granted to him notwithstanding the vigorous opposition of Solon. This guard P. increased either through the heedlessness or connivance of the people; and in 560 B.C. he made himself master of the Akropolis. Megacles and the Alkmaeonids fled. Solon retired. P. now the possessor not only of the semblance but of the substance of power, conducted the government with ability, discretion, and prudence. The fact that he attempted to make no change in the constitution or in the laws of Solon is in itself evidence of his tact and skill. But the first usurpation of P. was of short duration. Ere his power had taken root the rival chiefs had come to an understanding, and he was forced to evacuate Athens. Whether P., on his first deposition, left Attica is uncertain. Probably he did not. His property, however, was sold by auction, and he went into banishment. How he was employed during the six years that followed we know not. Meanwhile the old strife was renewed, and the coalition of the factions under Lycurgus and Megacles was broken up. Megacles now made overtures to P., and offered to reinstate him in the tyranny on condition of his accepting the hand of his daughter. To this P. consented. Hardly, however, had he entered upon his authority when Megacles, in consequence of a quarrel arising from P.'s treatment of his daughter, again combined with Lycurgus, and P. was once more driven from Athens. He fled to Eubœa. On reaching Eretria, P. deliberated with his sons as to his future course. Hippas advised a fresh attempt to regain his power, and this advice was adopted. Contributions were solicited from friendly cities, and in some cases large sums were cheerfully given. With these funds he procured mercenaries from Argos. Ten years were spent in these operations. At last with a Naxian, by name Lygdamis, he crossed into Attica and landed at Marathon. Friends welcomed him. Partisans flocked to his standard. His enemies now prepared to meet him. The two armies encamped at Pallene; and P., seizing a favourable opportunity, fell upon his antagonists and scattered them in all directions. The clemency of P. on this occasion is worthy of all praise. Instead of following up his success, he intimated to the fugitives that if they would go quietly to their homes they had nothing to fear. The whole measures of P. hereafter were directed to securing his supremacy and consolidating his power. The money by which he maintained his mercenary troops was derived partly from the silver mines of Laureon, and partly from the gold mines on the Strymon. P., now fairly established in the government, steadfastly maintained the institutions of Solon. For sixteen years he remained in undisturbed possession of his power, which he exercised with mildness and moderation. He died in 527 B.C., leaving the sovereignty to his two sons Hippas and Hippiarchus, known as the *Peisistratide*.

The character of P. is, upon the whole, a singularly amiable one. He did not, it is true, mount to power by a course of unimpeachable integrity, but, when he had attained the summit of his ambition, he made splendid use of his opportunities. Kindly, sympathetic, and humane, he won the esteem and goodwill of all, notwithstanding his usurpation. He encouraged agriculture among the poorer classes. To those who had no means of their own he gave cattle and seed. For the old and needy he secured provision. He was scrupulously attentive to the celebration of the religious festivals of Attica. The patron of the fine arts and the fosterer of literature, he was moreover the first editor of Homer. He adorned the city with many splendid structures, among which may be mentioned a temple to the Pythian Apollo, another to Olympian Zeus, the Lyceum, the Fountain of the Nine Springs, &c.

Pekan, or **Woodshock** (*Martes Canadensis*), a species of the Weasel family inhabiting N. America. The fur of this animal is of considerable value, and somewhat resembles that of

the Sable (q. v.). Its colour is a greyish brown, the lighter tint predominating on the upper parts. The P. lives in burrows excavated in the neighbourhood of rivers, and feeds on fish, crustaceans, &c.

Pekin, or **Pe-King** ('northern court,' in contradistinction to *Nanking*, 'southern court'), capital of the Chinese Empire, in the province of Chi-li, on the river Tung-hui, an affluent of the Pei-ho, 13 miles from the latter river, 50 S. of the Great Wall, and 100 from the sea, in lat. 39° 56' N., and long. 116° 27' E. It is situated in a fertile, well-cultivated plain, which, dotted with summer houses and gardens, rises at a short distance into woody hills. Good bituminous coal is drawn from extensive deposits to the N. and W., and excellent water is procured from numerous wells, and distributed through the city by carts and wheelbarrows. The climate, though severe, is not unhealthy, the temperature ranging from 10° to 105° F. The waters in the vicinity are covered with two feet of ice from December to March, while in summer the dust from the unpaved, undrained streets is a terrible scourge. The city consists of two parts—the Tartar city or *Nei-tching* ('within the walls') on the N., and the Chinese city or *Wai-tching* ('beyond the walls') on the S., together having a circuit of 25 miles. The native name of the two cities points to the original design, which was that the Chinese city should encircle the city of the Tartars. But the former has not been extended beyond the S. side of the latter, nor does the distinction of nationality any longer separate the inhabitants. Both cities are girt with walls of earth, cased on each side with brick, and opening every 50 feet in embrasures. The walls of the Tartar city are about 50 feet high, and vary in thickness from 40 to 52 feet. They are pierced by twelve gates, three of which lead into the Chinese city, and are dominated by massive watch-towers, loopholed for cannon. The walls of the Chinese city are only 30 feet high, and from 15 to 25 feet wide, but they are further strengthened by square towers or buttresses placed at intervals of 60 yards. Seven gates give access to the country. The gates of P., closed at sunset and opened at sunrise with great ceremony, are the chief stations of police, and the seat of customs.

The Tartar city consists of three concentric parts. The inner or prohibited city is confined by a red brick wall about 2 miles in circuit, and contains the Winter Palace where the emperor and his family reside, the Temple of Imperial Ancestors, the Hall of Imperial Portraits, the Imperial Library or Hall of the Literary Abyss, and various government offices. Encircling this, and girt by a yellow wall, the imperial city is the residence of the imperial princes and officials of the highest rank, and here are magnificent palaces, and temples and altars to Chinese divinities, the imperial gardens adorned by an artificial mountain supporting a splendid pavilion, and by an artificial lake bordered by beautiful groves. From the imperial printing-office issues daily the *Great Report*, the only Chinese newspaper, of which an English translation has appeared for 1872-76 inclusive. The official copy of this journal is of miserable proportions, but the copy sold every second day to the public is still further reduced by the withdrawal of all secret decrees and reports. The outer or Tartar city proper, more populous than the others, is the seat of six supreme tribunals, the Grand National College and the Great Medical College, and contains the famous Examination Hall, the Observatory (since 1279), the legations of Great Britain, France, the United States, and Russia, the temple of Confucius in which the emperor attends a grand annual service, a Lama temple, erected 1725-30, several Mohammedan mosques and Buddhist temples, a Roman Catholic cathedral, a Greek church, a Protestant chapel, &c. The Examination Hall is provided with numerous cells (ten thousand, it is said) for the candidates competing for public offices. The splendid Palace of Leang is the residence of the British Minister. The main streets, flooded with a grotesque and clamorous crowd, are lined by shops painted red, blue, and green, and at night are lit by torches and coloured lanterns. The character of the minor streets may be imagined from their bearing such names as 'Fetid Hide Street,' 'Dog's Tooth Street,' 'Dog's Tail Street,' 'Barbarian Street,' &c.

The Chinese city, densely crowded and utterly lacking in sanitary arrangements, is the great mercantile centre. Broad straight streets run from gate to gate and intersect each other at right angles. The centre of these is occupied by an elevated

carriage road, thronged with springless cabs, rude carts, and mules and camels with towering loads. One side of the streets is formed by brick houses of one or two stories, the other by stalls where is displayed abundance of showy merchandise. The chief buildings are the Temple of Heaven, built 1420, and the Temple of Earth, in the grounds of which the Emperor inaugurates the ploughing season at the vernal equinox. Here also are the Golden Fish ponds, the execution ground, the theatres, and other places of amusement. Visitors have frequently remarked that the whole city wears an appearance of decay. Riots are of common occurrence, and generally arise out of the defective manner in which the city is supplied with provisions. The total pop. of P. is estimated at from 1½ to 2 millions.

Centuries before the Christian era P. was the capital of *Tsu*, a kingdom overthrown by the Tsin dynasty in 222 B.C. It became the capital of the Kitan dynasty in 938 A.D., and was taken by Genhis Khan in 1215. Kublai Khan made it his residence in 1264. The court was removed to Nanking by the native emperors in 1369, but finally transferred back to P. by Yung Lo, the third member of the Ming dynasty, in 1421. A Portuguese embassy visited P. in 1517, but the representatives were imprisoned and subsequently put to death in 1523. intercourse began with the Russians as early as 1619, and in 1667 a Dutch embassy succeeded in concluding a commercial treaty. It was visited by Lord Macartney in September 1793, but little was known of it till 1860, in which year the French and English allies forced its surrender, and secured the peace of 24th October, allowing, among other privileges, a British envoy to reside here. The allies destroyed the famous Yuen-ming-yuen (lit. 'round and splendid gardens'), situated 8 miles N.W. of P. as a punishment for the treachery of certain mandarins. Foreigners are now freely allowed to visit the city, but not to trade within its precincts. See Fortune's *Yelo and Peking* (1863); *The Treaty Ports of China and Japan* (1867); and Dr. Rennie's *P. and the Pekingese* (1875).

Pela'gianism, the opinions which are associated with the name of Pelagius (q. v.), 'does not so much represent the notions of a single individual as a complete moral and religious system, which formed a decided contrast to the Augustinian doctrine regarding the relation of divine grace to the human will, and which took a firmer hold in the East than in the West,' owing to its affinity with the opinions of Origen (q. v.). Since Tertullian (q. v.) an opinion had prevailed in the West, which was unknown in the Eastern Church, that the sin of Adam had been transferred to his posterity as a predisposition to sin (see ORIGINAL SIN). This idea was combated by the Pelagians on the ground that it served as an excuse for moral indolence. Augustine's celebrated prayer, 'My God, bestow on me what Thou commandest, and command what Thou wilt,' was pronounced by Pelagius an absurdity, 'because it assumed that God can demand more than man can render, and what man must receive as a gift.' The radical principle of P. is that ability limits obligation: 'If I ought, I can; if sin be of the will, it can be avoided; if it be of necessity, it is not sin.' At the conclusion of the controversy, Augustinianism was triumphant in the West, although not recognised in the East, where P. was not officially condemned till the Council of Ephesus (431). The opinions represented by P. have been arranged under the three heads of Sin, Liberty and Grace, and Predestination. 1. In opposition to the conception of Augustine that the whole human race is a concrete totality, the logical consequence of which was the proposition that 'as all men have sinned in Adam, they are justly exposed to the vengeance of God, because of this hereditary sin and guilt of sin,' Pelagius regarded every human being as a moral agent, complete in himself, and separate from all others, 'so that he was in no way affected by the sin of Adam further than as a bad example. 2. Liberty and Grace.—In opposition to the view of Augustine that the grace of God is a creative principle of life producing the liberty of the will, which in the natural man is only free to do evil, Pelagius supposed that grace (i.e., everything which we derive from the goodness of God) was something added to the efforts put forth by the will of man, which was free to choose good as well as evil. 3. Predestination.—From the premises that man lies under the guilt of Adam's sin, besides being thereby so much predisposed to sin that none can possibly escape from this condition who are not supernaturally assisted, it logically follows in Augustine's system

that God 'in consequence of an eternal decree, and without any reference to the future conduct of men, had elected some out of the corrupt mass to become vessels of his mercy, and left the rest as vessels of his wrath to bear the just consequences of their sins.' According to P., on the contrary, the operations of grace always follow, or must have been deserved by, the free resolution to be good; so that God's predestination is founded solely on his foreknowledge of human actions. See Hagenbach's *Lehrbuch der Dogmengeschichte* (Eng. trans. Edinb. 1847), Neander's *Gesch. der Christl. Rel. und Kirche* (Eng. trans. Lond. 1858), and Dörner's *Augustinus* (1873).

Pelagius, the great opponent of Augustine (q. v.), was a monk of Britain, whose ecclesiastical name is perhaps a Greek equivalent of the Cymric Morgan ('sea-born'). Of his early life nothing is known, but Augustine himself tells us that by his rigid life as a monk he had gained universal respect; and in his writings he appears as 'a man filled with pain and indignation at the moral depravation of the great mass of the nominal Christians of his day.' P. also considered that the Augustinian doctrine regarding the corruption and weakness of human nature (see ORIGINAL SIN) only afforded excuses for moral indolence, and served as props for immorality. From this point of view he was led to deny that there was any such thing as a corruption of human nature, which had grown out of the Fall. Accordingly in the Western Church, where the doctrine of Augustine expressed the tendency of the time, he was regarded as a heretic. Coming to Rome about 400, P. there composed his commentaries on the Epistles of St. Paul, in which his peculiar views are expressed. The public outbreak of the controversy, however, was due to another, Coelestius, who held similar opinions, and who, as a younger man and trained advocate, was more ready to maintain his opinions in public. The two went together in 411 to Carthage, where Coelestius applied for ordination as a presbyter. Instead of getting it, however, he was accused of heresy, and condemned by a synod (412). When the attention of Augustine was called to the writings of P. as the teacher of Coelestius, he deemed it necessary to refute them. He also sent Orosius as an emissary to Palestine, whither P. had gone, and where his opinions were more congenial from their affinity with the opinions of Origen (q. v.), in order to warn the Church there against him; but although accused by Orosius and Jerome, P. was acquitted by two synods—at Jerusalem and Diospolis (Lydda), 415. Whereupon Augustine 'laid aside all forbearance, and opposed the doctrine of P. severely and bitterly in many works.' The heresy was now condemned by another synod at Carthage, 416; and although Zosimus, Bishop of Rome, at first sided with the Pelagians, when the African bishops in another synod (417) adhered to their former decision, which was confirmed by a general council at Carthage, 418, he joined in the condemnation, and excommunicated them. The controversy was decided by the Emperor Honorius against P., who was banished from Rome. His subsequent history is unknown. A peculiar importance attaches to P. The doctrinal questions that he was the first to raise are not yet settled; they have repeatedly, under different forms and with various modifications, been reiterated in the history of the Church, and the Pelagian view will, in all probability, continue to attract those who shrink from the tremendous conclusions of Augustine and Calvin, however irrefutable they may appear. Besides his *Commentaries*, P.'s chief works are *De Libero Arbitrio*, *De Natura*, *De Fide Trinitatis*. See Neander's *Gesch. der Christl. Rel. und Kirche* (Eng. trans. 1858), Wigger's *Versuch einer Pragm. Darstellung des Augustinismus und Pelagianismus* (Eng. trans. And. U.S. 1840).

Pelamis, a well-known genus of water-snakes or *Hydrophidæ*, of which the *P. bicolor* or black-backed P. is a good example. It is essentially a sea-inhabiting species, and is found swimming in the ocean at great distances from land. The tail is compressed, to fit it for serving as a swimming organ, and the nostrils are valvular. The colour is black above and yellow beneath, the tail being variegated with these colours. The average length is 2½ feet. The P. is poisonous, and belongs to the sub-order of *Colebrine* snakes.

Pelamys, a genus of *Teleostean* fishes, belonging to the *Scomberidae* or mackerel family, and represented by the Bonito (q. v.).

Pelargonioic Acid, one of the fatty acid series, having the composition $C_9H_{16}O_4$. It is obtained by distillation with water of the leaves of *Pelargonium roseum*, a species of the order *Geraniaceæ*. It is soluble in alcohol and ether, and very sparingly so in water. It is the last of the series, which is liquid at ordinary temperature and pressure, and boils at 500° C.

Pelargonium is a vast genus, the glory of the natural order *Geraniaceæ*, and is almost exclusively S. African. From *Geranium*, with which it was formerly included, and which name is still often applied to the cultivated plants, it is distinguished by having irregular instead of regular flowers, a spurred sepal, no glands on the disc, and four to seven fertile stamens only, instead of ten. The species are difficult to define from the very great facility with which they form hybrids, running into innumerable varieties by seed. They differ, too, in stem—being shrubby, herbaceous, or stemless; in root—tuberous or fibrous; in leaves—entire or variously divided; in their leaf-perfume—from an unpleasant to a grateful odour; and in their flower—from striking beauty to insignificance. The species possess, in different proportions, the astringent properties of the order. From *P. roseum* what is called 'oil of geranium' is extracted, for which purpose the plant is extensively grown in France. *P. capitatum*, another Cape species, and *P. odoratissimum*, a perennial trailing herb of S. Asia, likewise yield by distillation a fragrant oil. The tuberous rootstocks of some of the species attain a considerable size, those of *P. triste* being eaten at the Cape, and some are so curiously formed as to resemble corals in appearance.

Pelagians, the earliest known inhabitants of Greece, were also spread over the Troas, Crete, Southern Italy, and many of the *Ægean* islands. Their name has been variously connected with Peleg the son of Eber (Gen. x. 25), with *plazō*, *pelagos*, *pelargos*, &c., but is most probably akin to *peran*, *peraō*, in which case it would signify 'wanderers.' The theory of their Phœnician origin is forbidden by the scarcity of Semitic elements in classical Greek, and to assert the identity of the P. with the Etruscans is only to explain *ignotum per ignotius*. The ablest and most recent investigators of the subject hold the P. to have been of the same Aryan stock as the Hellenes, and to have entered Greece by way of the northern mainland. That Herodotus speaks of their dialect as 'barbarous' (i. 57) proves nothing, because he also includes in the promiscuous term 'Barbarians' the Thracians, Macedonians, and Illyrians, who are generally admitted to have been more or less distantly related to the Hellenes. Indeed in Max Müller's words, 'for the purposes of scientific classification it is almost impossible to make any use of the statements of ancient writers about these so-called barbarous idioms.' The P. seem to have been a peaceful race, occupied chiefly with agriculture, but possessing fortified towns, built in the style known to us as Cyclopean Architecture (q. v.). See the Histories of Thirlwall, Grote, Curtius, and Coxe.

Pelayo, son of Favila, Duke of Cantabria, was the first king of Asturias, and the twenty-eighth of the Gothic kings of Spain. Much of his history is involved in obscurity, and it is only known that after the battle of Guadalete (711), gathering the scattered forces of the Christians among the mountains of Asturias, he in 718 inflicted a severe defeat on the Moslems at Cangas de Onís, which, with another victory over Munuza, governor of Leon, prepared the way for the foundation of a kingdom whose capital was the city of Leon, and which, on P.'s death in 737 passed to Alonso el Casto.

Pelecanidæ. See PELICAN.

Pelew Islands form the W. portion of the Caroline Archipelago, and are situated in the N. Pacific in 7°-8°30' N. lat., 134°-136° E. long. They number twenty, and have an area of 346 sq. miles, that of the principal one, Babelthup, being 275 sq. miles. The area of the coral reefs which almost encircle them is computed by Dana to be six times greater. The islands are fertile, and the bread-fruit, coconut, sugar-cane, and banana, grow well, while cattle and pigs are reared in considerable numbers. The inhabitants, who were estimated to number 10,000 in 1873, and are decreasing, are of the Malay race, with

an evident infusion of Papuan blood. Every village forms a republic, independent in itself, but co-operating with the others. There also exists among the members of both sexes a curious system of co-operation for mutual help and protection, called the *cllobbergoll*. The P. I. were discovered by Drake in 1579, and were brought into prominent notice by the wreck of the *Antelope* on one of them in 1783, followed by the visit of Prince Lee Boo to England. In common with the rest of the Carolines, the P. I. are claimed by Spain.

Pelican (*Pelicanus*), a genus of Natatorial or Swimming Birds, the type of the family *Pelecanidae*. In this family the bill

Pelican.

is long, straight, pointed, and broad at its base. The nostrils are narrow. The skin of the throat, or that between the halves of the lower jaw, may be dilated to form a pouch; the wings are long, and have their first quill longer than the others. All the toes are united by the web, and the face and throat are partially covered with feathers. The genus *Pelicanus* itself has a long hooked bill, and a short and rounded tail. Of this genus the common P. (*P. onocrotalus*) is a well-known example. This bird belongs to S. Europe, Africa, and parts of Asia. It occurs in flocks, which frequent sea-coasts. Its average length is 6 feet, the spread of the wings measuring about double the length of the body. The colour is white, the plumage having a delicate pink tint. The feathers of the breast are yellow, and the quills of the wings black. The bill is yellow, but red at the tip. The P. is well known for its *gular pouch*, formed by an enlargement of the skin of the throat, and depending from the lower jaw. In this cavity, the capacity of which is equal to about two gallons, the fishes caught are received. The tongue of the P. is of small size. The bird is frequently pursued by other birds, and made to disgorge its prey from the pouch. Its nest is rudely constructed of grass, and the eggs, two or three in number, are of white colour. The young are fed from the pouch of the parent. The legend that the P. fed her young with her blood arose from the fact that the bird presses the bill against the breast to extract the fishes, the red tip of the bill appearing like a blood spot on the white feathers. Another species (*P. rufus*), the red-necked P., inhabits the W. Indies.

Pelion (mod. *Zagora*), a rugged mountain ridge in Thessaly, stretching from Ossa southwards to the promontory of Sepias. On the eastern side it rises almost precipitously from the sea, causing the coast at that part to be quite devoid of harbours. It is about 5000 feet high, and is still covered with those dense forests of oak, chestnut, elm, and pine, which procured it the title of 'woody' in Homer's time (*Od.* xi. 315).

Pelissier, Jean Jacques Aimable, Duc de Malakoff, and Marshal of France, was born at Maromme (Lower Seine), 6th November 1794, became a lieutenant in the army (1815), served with distinction in the Spanish campaign (1823), and in the expedition to the Morea (1828). He took part under Bourmont in the conquest of Algiers (1830), was made a staff officer, and during 1831-39 was employed in France as adjutant. He then returned to Algiers with the rank of lieutenant-colonel, and was present in all the succeeding campaigns. In 1846 he suffocated with smoke some hundreds of Arabs who had taken refuge in the caves of Dahra and refused to surrender. The act occasioned a loud outcry in the European press. In 1850 P. was appointed a general of division, and inspector-general of infantry. Early in the Crimean War, he was placed at the head of the 1st *Corps d'Armée* (January 1855), and when Canrobert in the May following resigned the office of commander-in-chief, P. succeeded him. The storming of the Malakoff by the French troops (8th September) led to the fall of Sebastopol. In consequence of this, P. received the title of Duc and the rank of marshal. In 1858 he was sent as ambassador to London, and in 1860 as governor-general to Algiers, where he died 22d May 1864.

Pell'a, the capital of Macedonia, was situated on a hill, in the midst of marshes, near the modern village of Neokhori. It

was the birthplace of Alexander the Great, and the residence of the Macedonian monarchs from 360 to 168 B.C., when it surrendered to Æmilius Paullus, and from a splendid city sank to a mere station on the Via Egnatia. It is last mentioned by Hierocles, a writer of the 6th c. A.D.

Pell'agra is the name of a loathsome skin disease, endemic in some parts of Spain (where it is called *flema salada*), in Portugal, the Tyrol, and the N. of Italy. P. is seen in its most intense form, probably in Lombardy, where the skin is covered with tubercles and rough scales, and where it is associated with general debility, vertigo, staggering gait, melancholia, and frequently epilepsy. The melancholia characteristic of the disease has so frequently led to self-destruction by drowning, that it has been distinguished by the appellation of Hydromania. *Pellagrous insanity* is met with especially in Northern Italy, and, according to recent observers, also in certain parts of France (Rennes, Angers, &c.), and appears to depend upon a constitutional disease, the special cause of which is still unknown, but which is manifested particularly by an exanthematous exanthema, chronic diarrhoea, anæmia, and marasmus. See *Traité de la Pellagre*, par le Docteur E. Billod (Paris, 1870).

Pellow, Edward. See EXMOUTH, VISCOUNT.

Pell'ico, Sil'vio, an Italian poet and politician, was born at Saluzzo in Piedmont, 24th June 1788. In his sixteenth year he accompanied a relative to Lyon, where he almost forgot his native tongue, when Foscolo's *I Sepolcri* rekindled in his breast such a love of his fatherland and of freedom that he returned to Italy. After spending some time as a private tutor in the family of Count Luigi Porro Lambertenghi, whose house was a rendezvous for all the *beaux esprits* of Milan, P. published his tragedies *Laodamia* and *Franческа da Rimini* (1818). Along with some other patriotic friends he started the journal *Il Conciliatore*, became suspected of Carbonarism, was arrested (1820), imprisoned, and in January 1822 formally condemned to death. The sentence was changed by the Austrian Emperor into a fifteen years' captivity. In 1830 P. was released through the intercession of his friends. The story of his sufferings is told in *Le Mie Prigioni* (1833), a work of exquisite pathos and strange, perplexing humility, as if composed under the inspiration of those hyperboles of forgiving love that startle us in the Sermon on the Mount. *Le Mie Prigioni* has gone through innumerable editions, and been translated into most of the languages of Europe. P. died at Turin, 31st January 1854. Besides the works mentioned, P. published in 1832 the tragedies *Gismonda da Mendrisio*, *Lenoniero da Dertona*, and *Eroliade*; in 1833 *Tommaso Moro*; and in 1837 a collection of his *Opere inedite*. An edition of his posthumous works, memoirs, and letters was published at Turin (1855 *et seq.*). See Chiala's *Vita di Silvio P.* (Tur. 1852), and work of Bourdon (1868).

Pell'itory, or Pell'itory of the Wall (*Paritaria*), is a small genus of *Urticaceæ*, consisting of shrubby herbs, with alternate entire leaves, polygamous flowers, four stamens, papillose stigmas, and fruit included in the enlarged calyx. *P. officinalis* is frequent in Britain on old walls, and neighbouring wastes and hedge-banks. As a rustic medicine it is apparently used for various purposes in different districts of the country. Both the scientific and the popular names of the genus are derived from Latin *paries*, on account of walls being the usual site of growth.

Pell'itory, of Spain, is the *Anacyclus Pyrethrum* of botanists, one of a small genus of *Compositæ* with much-cut leaves, terminal solitary flower-heads, having white ray-florets, resembling in appearance the familiar chamomile. The above-named species is a native of N. Africa, Syria, and Arabia, from whence it has been introduced into cultivation to the S. of Europe and other places. It is grown for the sake of its roots, which are used in medicine under the name of 'Pyrethri Radix.' As imported, they are short tapering pieces about half an inch in diameter, externally dark brown, covered with dark shining points, internally dirty-yellow, breaking with a resinous fracture. When chewed a tingling sensation in the mouth and throat is caused, followed by a glowing heat and a copious flow of saliva. A small piece placed in the mouth and gently masticated is

of much benefit for toothache; and has also been used with more or less success for facial neuralgia, and paralysis of the tongue.

Pelopidas, a famous Theban general and statesman, was descended from an ancient and noble family, but early joined himself to the democratic party. As a consequence of this, on the victory of the oligarchical faction, aided by the Spartans in 382, P. was forced to flee from Thebes, and betook himself to Athens with 400 followers. In the autumn of 379, after having completed a plan for the overthrow of the oligarchy, he returned secretly to his native town with twelve of his associates, slew there the chiefs of the ruling party, including Leontiades the Spartan leader, and was elected Boeotarch, along with Melon and Charon. In the war which now followed with Sparta, P. secured the alliance of Athens, and defeated the Spartans at Tegyra in 375, and at Leuctra in 371. After this he directed his policy chiefly towards extending the Theban influence in the north, affording assistance to the Thessalian towns against Alexander of Pherae, and acting as mediator in the internal dissensions of the Macedonians. Sent as an ambassador to Thessalia in 368, P. was taken prisoner by Alexander, but was rescued in the following year by the Theban army under Epaminondas. Shortly after this he went to Susa as ambassador to the King of Persia. In 364 he undertook another campaign on behalf of the Thessalian cities against Alexander, whom he defeated in the battle of Kynoskephalæ, though P. himself was killed. He received a magnificent burial from the Thessalians. In private life P. was distinguished by the disinterested generosity with which he applied his large fortune to relieve the wants of his friends. He lived always in the greatest intimacy with Epaminondas, whom he equalled in patriotism and amiability of character, though he was inferior to him in political and military genius. See Plutarch's *Pelopidas*, and Diodorus Siculus, xv. 62-67, 71, 75, 80, 81.

Peloponnesian War, the struggle for supremacy between the democratic Ionian and the aristocratic Dorian races, extended over twenty-seven years, commencing with the attempt of the Thebans to surprise Platæa, May 7, 431 B.C., and closing with the surrender of Athens to Sparta in 404. On the side of Athens were Chios, Lesbos, Samos, and other subject islands of the Ægean, Platæa, Coreyra, Zacynthus, the majority of the Acarnanians, the Messenians of Naupactus, and the Greek colonies in Asia Minor, Thrace, Macedonia, and on the Hellespont. The Peloponnesian Confederacy included all the states of the Peloponnesus, with the exception of Argos, besides Phocis, Locris, Megaris, Boeotia, Leucas, Ambacia, and Anactorium. The history of the war was written by Thucydides up to 411, and concluded by Xenophon. See HELLAS.

Peloponnesus (Gr. 'island of Pelops'), the ancient name of the Morea (q. v.), styled by Homer *Argos* or *Apia* ('distant land'). According to Thucydides the P. was divided into five parts, but a more usual division was into the six larger states, Achaia, Elis, Messenia, Laconia, Argolis, and Arcadia, and the four smaller, Corinthia, Sicyonia, Phlasis, and Cleonæ.

Pelops, according to one Greek myth, was slain by his father Tantalus, and served up at a banquet given to the gods. Their omniscience was undeceived, Demeter alone, lost in sorrow for Persephone, eating a part of one shoulder. Thereupon Hermes restored the lad to life, and Demeter supplied the missing member by one of ivory. To a later myth belong P.'s Phrygian origin, his wandering to the peninsula called after him the Isle of P. (*Peloponnesus*), and his marriage with Hippodamia (q. v.). She bore him two sons, Atreus and Thyestes, whom she instigated to the murder of their step-brother, Chrysippus, a crime that drew down on the house of Tantalus its final doom. P. was honoured at Olympia above all heroes, and his tomb was shown near the banks of the Alpheus.

Pel'try (Fr. *pelletterie*, 'furriery,' from Lat. *pellis*, 'a skin'), the skins of furred animals. The pelt is either the undressed hide, or the skin prepared without the removal of its hairy or woolly covering. A *pelisse* is a furred coat or robe. See FURS AND FURRIERY.

Pelusiæum (Gr. 'clayey'), a city of Lower Egypt, lay about 24 miles from the sea, on the easternmost arm of the Nile delta, near the modern Damietta. It is the *Sin* of Ezekiel (xxx. 15, 16), who terms it 'the stronghold of Egypt.' The 'great anguish' foretold by the prophet found fulfilment in the surrender of the city to Cambyes (525), to Alexander the Great (333), to Antiochus Epiphanes (173), to Marcus Antonius (55), and to Augustus (31 B.C.). P. suffered greatly in the Persian invasion of 501 A. D., and after its final conquest by the califs in the 7th c., drops out of history, the Ostium Pelusiæum becoming choked with sand.

Pel'vis (Lat. *pelvis*, 'a basin'), the name applied to the bony basin or girdle giving support to the hind limbs of Vertebrata, and formed in chief by the 'haunch bones.' In man, the P. is

ADULT MALE PELVIS SEEN FROM BEFORE, IN THE ERECT ATTITUDE OF THE BODY.

1, 2, anterior extremities of the crests of the ilia in front of the widest transverse diameter of the upper or false pelvis; 3, 4, acetabula; 5, 5, obturator foramina; 6, sub-pubic angle or arch.

formed of two *ossa innominata* or haunch-bones, which are united in front to form the *pubis*, and between which the *Sacrum* (q. v.), and *coccyx*, or lower portion of the spine, is wedged behind. The *false P.* is the name given to the upper and expanded portion of the basin, as defined by the *ilio-pectineal* line. The *true P.* is the deeper part of the cavity situated below this line, and is of smaller capacity than the false, but more completely basin-shaped. The *inlet* of the P. is heart-shaped, and is somewhat encroached upon behind by the *promontory* of the sacrum. The *outlet* is the lower circumference of the P. below the pubis. The P. is regarded as possessing three chief diameters—*antero-posterior* (or *sacro-pubic*), *transverse*, and *oblique*. The average measurements of these diameters are 4 inches, 5 inches, and 5 inches respectively. The cavity of the true P. contains part of the *organs of generation*, the *bladder*, and the *rectum*, or terminal portion of the intestine. The rectum lies posteriorly, within the curve of the sacrum. The bladder is partly just behind the *symphysis pubis*. The uterus and vagina in the female are between the bladder and rectum. In the erect posture of the body the pelvis occupies an oblique position in reference to the trunk. The hollow of the sacrum, instead of looking anteriorly, looks downwards and forwards, the base of the sacrum in the female being about four inches higher than the part of the P. or *symphysis pubis*. The *axes* of the P. form a highly important study in reference to the mechanism of *parturition*. The plane of the inlet (as regards the true P.) lies in a line carried from the base of the sacrum to the upper border of the pubis. If this line be intersected at right angles at about its middle by another line, the latter line in front would correspond with the *umbilicus* or *navel*, and behind with the middle of the *coccyx*; the axis of the inlet being thus shown to be directed downwards and backwards. The axis of the outlet is directed downwards and forwards, and the axis of the cavity is curved. The female P. differs from that of the male in being as a whole lighter; the bones are of more slender make, and their muscular ridges are less plainly marked. The hollows of the ilia or haunch-bones are shallower

than in the male, and the spines of the ilia are more widely separated, giving to the female P. its greater breadth. The inlet and outlet are more capacious than in the male, and the pubic arch is wider. These distinctive characters are acquired after puberty.

The anatomical composition of the P. shows it to be composed of two *ossa innominata* or haunch-bones, together with the *sacrum* and *coccyx* already mentioned. Each *os innominatum* consists of three distinct bones, which in the adult are firmly

ADULT FEMALE PELVIS.

Similarly placed with that shown in the preceding figure, and illustrating, by comparison with it, the principal differences between the male and female pelvis. The numbers indicate the same parts as in the preceding figure.

ossified together. At birth the three bones are distinct, the P. being completely ossified at about the twenty-fifth year of life. These three pieces unite to form the cup-shaped cavity named the *acetabulum*, which receives the head of the thigh-bone in the formation of the hip-joint. The bones entering into the composition of each innominate bone are respectively known as the *ilium*, *ischium*, and *pubis*. The *ilium* forms the flattened and expanded part of each haunch-bone, and appears as the prominence of the hip. The *ischium* is the lower part of the haunch-bone, its tuberosities being represented by the 'buttocks'; while the *pubis* forms the front portion of the P., and supports the external generative organs. The *ilium* is smooth and convex in front, and deeply concave behind. The *crest* or ridge of the ilium forms the well-recognised 'flank,' and gives attachment to the muscles which constitute the walls of the abdomen. Its lower part enters into the formation of the *acetabulum*. The *external surface* of the bone gives origin to the muscles of the buttock; the *anterior face* is hollowed for the *iliacus* muscle, and the *internal surface* articulates with the *sacrum*. The *ischium* is a three-sided bone, with a prominent *tuberosity*, on which the body rests in sitting, and which gives attachment to various important muscles. The *pubis* consists of a *horizontal* and a *descending ramus*. The inner extremity of the *body*, or horizontal ramus, joins its fellow of the opposite side to form the 'pubis,' while the descending ramus unites with the ischium below. The *acetabulum*, or socket for the head of the thigh-bone, is a deep, cup-shaped cavity, the rim of which is broken at one point (the *cotylod notch*) through which blood-vessels and nerves pass inwards to the hip-joint. The *obturator foramen* is a large opening between the ischium and the pubis, oval-shaped in the male, and somewhat triangular in the female.

All vertebrates have not a P., and even in the mammalia, as exemplified by the whales, the P. may be represented in a very rudimentary condition. In birds (save in the ostriches) the halves of the P. are not united to form a *pubis symphysis*, the open condition of the P. having reference probably to the process of egg-laying.

Diseases of the P.—Contusions of the walls of the P. are very common from the passage of carriage-wheels over the body, from crushes, kicks, &c. Fracture of the P. is usually a very grave injury, and specially because of the great violence by which it is usually produced, and the risk of injury to the pelvic viscera. Partial fractures may involve little or no danger, and no treatment beyond rest is required, but the prognosis will de-

pend, in a great measure, on the presence or absence of visceral lesion. In the disease of the bones called Rickets (q. v.), the P. is often very much deformed, its outlet being narrowed, the tuberosities of the ischia pressed towards each other, and the pubic arch widened, or the pubes pressed backwards towards the sacro-vertebral angle, and the ischia thrust outwards. There are cases on record in which the P. is retarded in development, so as to retain in mature life the same relative size of infancy. Deformity of the P. may be of comparatively little importance in the male, but it is always of serious importance in the female, as complicating the function of childbirth. Female children, therefore, affected with rickets should be attended to with the utmost care, so as to avoid deformity of the P., which may render natural parturition an impossibility. Abscess of the P. may be caused by disease of the bones, or of the soft parts, or by the gravitation of matter in connection with disease of the spinal column. In such cases the abscess should not be interfered with until it is on the point of bursting, and then it should be opened and subsequently dressed on strictly antiseptic principles.

Pembroke (Cymr. *penn* and *bro*, 'the head of the district'), a town in S. Wales, on a navigable creek of the Milford Haven, 9½ miles W. of Tenby by rail, and 264 W. by N. of London. It consists mainly of a long irregular street, gradually ascending westward to a bold rocky promontory on which stands the remains of P. Castle. The stronghold came into the possession of Gilbert Strongbow, Earl of P., in the reign of Henry I., and within it Henry VII. was born in 1457. In 1648 the Royalists held it against Cromwell for six weeks. The circular keep is 75 feet high and 163 feet in circuit at the base, with walls 14 feet thick. Almost the only buildings of interest in the town are the church of St. Michael, in Norman style, and that of St. Mary, with a large square tower. P. Dock or Pater, 2½ miles W. and opposite Milford, is a seaport and the W. terminus of the P. and Tenby Railway. The Government marine works cover an area of 80 acres, and comprise graving docks, slips, and basins, engine-houses, foundries, and workshops. Fortifications enclosing the dockyard have been constructed at a cost of over £250,000. There is some foreign as well as considerable coasting trade, and steamers ply to Bristol, Waterford, &c. Small vessels laden with anthracite coal, during spring tides can reach the small quay of P. itself, on the N. side of the castle. P., with Tenby, Milford, and Wiston, returns one member to Parliament. Pop. of P. in 1871, 15,450; of P. Dock, 9534.

Pembroke College, Cambridge. was founded in 1347, by Mary de St. Paul, widow of the Earl of Pembroke, and was richly endowed by Henry VI. It is governed by a master, and has thirteen fellowships (four of them clerical) and twenty-four scholarships, viz., three of £80, nine of £60, six of £40, and six of £20, besides the Bowes Scholarship of £60, and the Blackrode Exhibition of £70. The chapel was designed by Wren, and new buildings are now (1878) in course of erection, including a library 90 feet in length. P. C. presents to twelve livings, and in 1877 had 104 members of the senate, 79 undergraduates, and 238 members on the boards.

Pembroke College, Oxford, originally Broadgates Hall, was founded by James I. in 1624, at the cost of Thomas Tesdale, of Glympton, Oxfordshire, and Richard Wighbrick, of Ilsley, Berks, and took its name from William Herbert, Earl of Pembroke, who was then Chancellor of the University. It is governed by a master, and has ten fellowships and twenty-four scholarships, six of the latter being open to competition. P. C. presents to seven livings, and in 1876 had 168 members of convocation, 84 undergraduates, and 297 members on the books.

Pembrokeshire, the most westerly county of Wales, is bounded N. and W. by St. George's Channel, S. by the Bristol Channel, and E. by Cardigan and Caernarthen. Area, 393,682 statute acres; pop. (1871) 91,998. The county, the southern promontory that continues the sweep of coast-land enclosing Cardigan Bay, has an irregular outline, indented chiefly by the beautiful expanse of St. Bride's Bay, and by the long, jagged inlet of Milford Haven, one of the finest of all natural harbours. The principal projections of the coast, which in great part is wild

and precipitous, are St. David's Head, St. Ann's Head (the horns of St. Bride's Bay), St. Govan's Head, and Penbrush Point. Off St. David's Head are the islets Ramsey, N. and S. Bishop, &c.; opposite St. Ann's Head, Skomer Island, Skokham Island, and the Smalls. In the N. the Percelley Hills traverse the county, and terminate in St. David's Head, attaining a height of 1754 feet. The surface generally is hilly and fertile, while the streams are very small, the only considerable ones being the E. and W. Cleddau, entering Milford Haven, and the Teivy, on the N.W. boundary. In 1876 there were 57,850 acres under corn crops, 13,702 under green crops, 35,610 in clover, sainfoin, and grasses in rotation, and 186,035 of permanent pasture. Barley, oats, wheat, potatoes, and turnips are the leading crops. The number of horses was (1876) 13,363; of cattle, 78,506; of sheep, 113,234; and of pigs, 24,895. P. has a mild, humid climate. The great S. Wales coalfield enters the county, but the anthracite seams vary in thickness from 6 feet to only a few inches. There is also some lead, iron, and slate wrought. The county sends one member to Parliament. Besides Haverfordwest, the county town, the centres of population are St. David's, Pembroke, Milford, and Tenby. P. has a singularly interesting local history. Such names as Hasegard, Freystrop (doubtless *Freysthorp*), and Milford (a true *fjord*) point to early Scandinavian occupation. The English district in the S. of P., or 'Little England beyond Wales,' is the latest Teutonic settlement in Britain. From the direct witness of William of Malmesbury, and other contemporary writers, Henry I., among his measures to keep the Welsh in order, planted a colony of Flemings in Dyfed, the modern P. The colonists seem to have thoroughly ousted the Briton, for the one speech of the district is English, and most of the places have received fresh names. How the Flemings came to speak English is a standing local puzzle. But Flemish and English are both dialects of Low Dutch, and closely resembled each other in the 12th c. The English district is naturally rich in castles.

Pemmican, or **Pemican**, a kind of preserved meat originally prepared by the North American Indians, which consisted of buffalo flesh or venison deprived of its moisture by exposure to the sun's rays, and afterwards pounded and packed into bladders for future use. Similar preparations of beef have been furnished to various British Arctic expeditions. As an article of food P. has little value, and other preserved meats, which retain more of the nutritive elements of meat, have entirely displaced it. See PRESERVATION OF FOOD.

Pemphigus, or **Pompholyx** is a skin disease, the eruption consisting of large bullæ, usually preceded by fever and constitutional disturbance, and locally by irritation and itching. When they burst they are succeeded by large brown crusts. The scabs fall in the course of three weeks, leaving the skin beneath of a dusky red hue, but perfectly sound. When the bullæ appear at once, the affection terminates in one or two weeks, but when they are developed at successive periods the disease may extend to three weeks or a month. The disease is one of debility, favoured by intemperance, bad diet, or cold, or it may be due to syphilis. The acute form may be treated by cooling medicines, nutritious diet, and mild local dressings. In the chronic form tonics should be employed, especially mineral acids and quinine, hydriodate of potash and arsenic. The inflamed skin should be anointed with benzoated zinc ointment, or dusted over with the oxide of zinc or starch powder.

Pen. See PENS.

Penal Servitude. The difficulties of finding colonies for the transport of criminals has made it necessary to substitute P. S. for transportation. Preceding Acts are amended by 27 and 28 Vict. c. 47, under which no sentence to P. S. for any offence committed after 1864 is to be for fewer than five years. A former conviction for felony makes the shortest term of the sentence seven years. The Crown may grant a license to convicts to be at large in the United Kingdom or Channel Islands, or in part of the same. See TICKET OF LEAVE.

Penalties (Fr. *pénalité*, from Lat. *penalis*, 'penal'). Any one failing to perform any act to which he has become bound, will be liable in damage to the person who suffers by his breach of agreement. But in estimating this damage, when there has been no fraud, indirect damage is not taken into amount. Thus

the failure to pay money at a stipulated date may occasion indirect damage to the creditor, but the law cannot estimate this, therefore the creditor's legal claim is limited to the principal sum with interest, and the expenses to which he has been put. Statutory penalties can, as a general rule, be sued for by any one, and statutes not unfrequently declare that the person suing shall be entitled to the whole or part of the P. which it imposes. It is usual when a penalty is imposed on an offence by Act of Parliament to state a maximum sum, leaving the modification to the discretion of the judge.

Penance (Lat. *penitentia*) was the system of discipline to which persons who had been excommunicated for gross and scandalous offences were required to submit in the early Christian Church, before being readmitted to communion, as outward proof of their inward penitence and remorse. (See EXCOMMUNICATION.) As those excommunicated were supposed, like the unbaptized, to be under the dominion of Satan, they had, like the Catechumens (q. v.), to undergo a period of probation under the name of penitents. Penitentiary (q. v.) priests were appointed at the time of the Decian persecution (250), and by the end of the 3d c. the Penitents were divided into four classes: the Weepers, the Hearers, the Kneelers, the Co-standers; the last three corresponding with the Catechumens.

When a penitent desired to be admitted to do public P., and his petition was granted, he received imposition of hands from the bishop, and was obliged to change his dress for one of sackcloth, to make confession of his sin, 'to prostrate himself before the presbyters of the Church, to kneel before the friends of God, and beg of all the brethren that they would become intercessors for his pardon.' According to some canons they had also to sprinkle ashes on their head, or even their whole body; to shave their head if a man, or cut their hair or go with it dishevelled and wear a veil if a woman; to fast privately, and especially to observe all public fasts; to abstain from all ablations, from marrying, and, if married, from the marriage bed; always to pray kneeling, and to show great liberality to the poor. In later times corporal austerities, as the endurance of heat and cold, the wearing of hair-shirts, flagellations, &c., and menial offices, as burying the dead, &c., were largely introduced. The time of P. usually lasted several years; sometimes even to the hour of death. In Africa and Spain readmission was denied for ever for certain offences, unless a martyr interceded for the penitent.

Step by step the system was made more minute and elaborate. P. was extended to all sins, even the most secret; but alongside of this means were devised for relaxing its primitive severity, and for granting dispensation. The practice of auricular confession, which had originated with the Penitentiary priests, and which had fallen into entire disuse in the East, acquired ever-increasing importance in the West. Thus those who voluntarily confessed to a priest were thereby exempted from performing public P., and received absolution before undergoing the private P. which was imposed, although not at once admitted to communion. The barbarous races of Europe long resisted the system of P., and the system which was imposed upon them about the 8th c. was an accommodation to their own customs. They had always been accustomed to pecuniary mulcts, which had been adopted into their jurisprudence, so that by paying a fine a thief or a murderer could escape the punishment due to his crime. The regulations of P. among them had regard to the same customs, and persons were allowed to escape the P. to which they were liable by the payment of a certain sum of money. The system of P. had received a great impulse by the publication of the Penitential of Theodore of Canterbury (about 670), in which sins and penances were systematically classified, forming a complete confessor's *vade mecum*; but it was gradually subverted after the introduction of the system of Indulgences (q. v.), which was first adopted among the barbarians, and when found to be very profitable to the bishops, was adopted in the 12th c. on a gigantic scale by the Popes.

The early custom of associating P. with baptism, by making a distinction between sins committed before and after baptism, led the Schoolmen (q. v.) to class P. among the sacraments. According to fully developed Roman Catholic doctrine the matter of the sacrament is the contrition or remorse, the Confession, which must be auricular, and the Satisfaction. The form is the act of absolution by the priest.

At the Reformation the Reformers desired to return to the usages of the primitive Church in respect of the exercise of ecclesiastical discipline, the relaxation of which they regarded as one great cause of the universal corruption of religion which prevailed in the Church. Accordingly a very rigorous system was established at Geneva by Calvin, was adopted to some extent by the English Puritans, and more fully by the Scotch Reformers. In Scotland, any one guilty of gross and scandalous sin had to appear at the church door dressed in sackcloth while the congregation were assembling, and afterwards take their place in full view of the whole congregation, and after confession of their sin be rebuked by the minister therefor. But, just as in the Catholic Church, the full rigour of this P. began to be remitted on payment of a sum of money to be expended on charitable purposes, and it has now dwindled down to a rebuke by the kirk-session. See CHURCH DISCIPLINE.

Penang, Pulo (*i.e.*, 'betel-nut island'), or **Prince of Wales' Island**, a British possession included in the Straits Settlements (q. v.), and situated at the northern extremity of the Strait of Malacca, opposite Wellesley Province, on the mainland of the Peninsula, from which it is separated by a channel 7 miles wide. Area, 106 sq. miles; pop. (1871) 61,797, of whom 20,355 were Malays, 23,911 Chinese (5120 females), 5615 Klungs, a native race, 3160 Jawi-pakans, 3848 Hindus, 1077 Bengalis, besides 343 Europeans, many Arabs, Javanese, Siamese, &c. The island is 14 miles long from N. to S., and is traversed by a well-wooded mountain ridge of granite and mica schist, which in the N., at the sanatorium of Strawberry Hill, reaches a height of 2922 feet. P. is visited daily by a grateful sea-breeze, and has a temperature in the coast-lands of from 80° to 90°, and at Strawberry Hill of 62° to 75°. Rain falls during all except the first two months of the year. On the W. and S.W. coasts are the plantations, and along the E. coast stretches a fertile and populous belt of land, laid out for the most part in gardens. The chief products are sugar, coffee, cloves, pepper, nutmegs, ginger, rice, sago, and timber. P. is also rich in fruits. The capital, George Town, lies at the N.E. end of the island, and had a pop. in 1871 of 30,729. Its harbour, defended by Port Cornwallis, is safe and commodious. P. was acquired by the East India Company in 1786, and is now under a lieutenant-governor, who is a member of the Executive Council of the Straits Settlements.

Penang Lawyers is a name given in the trade to the stems of two species of small fan-palms (*Licuala*), natives of Pulo-Penang. They are imported in the rough state, and after being made smooth and polished are manufactured into walking-sticks.

Penates. See LARES.

Pen'cil (Old Fr. *pinzel* (mod. Fr. *pincean*), from Lat. *penicillum*, a dim. of *penis*, 'a tail'), a term applied to two kinds of instruments—one a small hair-bush used by painters and artists in laying on colours, the other a cylinder of wood containing a slender rod of plumbago, coloured chalk, or prepared slate, for use in writing or drawing. A thin naked cylinder of slate is also called a slate-P., but a similar rod of coloured chalk is termed a Crayon (q. v.). Artists' pencils are made of the hair of the sable, badger, camel, or hog, or of swan's down, secured to a wooden handle.

Black-lead P. (familiarily so called, although the name is misleading, since they contain no lead) were first employed in Italy in the 16th c. (Beckmann, *History of Inventions*). Previously a style formed of lead and tin was used for drawing lines on paper. These lines, however, were very faint as compared with the black-lead coloured marks of native plumbago, and probably that substance acquired its name of *black-lead* as much from this circumstance as from its general appearance. Keswick, in Cumberland, has long been the principal seat of the black-lead P. manufacture in England, the plumbago being found in a very pure state at Borrowdale, and from it the best English lead pencils are made. Formerly the *leads* were cut from slips sawn off the block as taken from the mine; but since the supply of large pieces of plumbago began to fail, the small fragments have been utilised for the purpose by an ingenious process devised by Mr. Brockedon. The fragments are reduced to powder and then compacted by moderate pressure. Thorough cohesion is not obtainable by simple pressure, on account of the particles of air resident in the interstices of the mass; the air must therefore be removed. This

is done by glueing paper all round a block, then perforating the paper, to allow the air to escape, and exhausting it under the receiver of an air-pump. The orifice is then closed with a wafer, and the compacted block is afterwards properly solidified by hydraulic pressure, and may then be sawn with as great facility as the native mineral. Inferior qualities of plumbago, derived from foreign sources, are, after being washed and purified, similarly formed into artificial blocks. Only the first quality of lead pencils is made from pure plumbago. The numerous inferior varieties are manufactured from a mixture of plumbago and clay, in varying proportions, by the method invented by M. Conte of Paris. The two ingredients are separately reduced to fine powder, and after the plumbago has been calcined, they are ground together, and thoroughly incorporated with water into a homogeneous paste. The leads are moulded from the pasty mass by pressing it into narrow grooves (square in transverse section) cut in a wooden board. When dry the moulded rods are shaken out, and are next hardened by exposure in a crucible to a high temperature. Another method of forming the leads is to force the pasty mixture, partly freed from moisture, through a hole in the bottom of a cylindrical press, the threads so obtained being afterwards cut into lengths and baked as already mentioned. The wooden cases in which the P. leads are enclosed are generally prepared from the P. cedar (*Juniperus virginiana*). The wood is cut into slips by machinery, and those slips which are to receive the leads are grooved. The grooves are filled with the leads, and the ungrooved slips of wood are then glued on as covers. After drying, the parallel-sided rods thus constructed are rounded in a cutting machine, then polished, varnished, and stamped with the name of the manufacturer and letters indicating the quality of the lead P. The best Keswick pencils are simply polished and not varnished. The letters stamped on pencils are H, signifying hard; IIII, harder; and HHH, very hard; B, for black; BB, blacker; BBB, very black; and HB when hard and black. There are also degrees of *fineness* indicated by the letter F. Coloured pencils are made in a similar fashion, only the earthy material is not baked, because heat would destroy the colour.

Pencil cases, of which there are numerous varieties in general use, were invented by Mr. Mordan in 1822, and the small cylinders of plumbago which they contain are formed by forcing square strips through circular holes drilled in ruby, the hardness of the plumbago necessitating the employment of that precious material.

Pen'da, a famous Mercian king of the 7th c. who for a time successfully resisted the progress of Christianity in England. In 626, at the age of fifty, he ascended the throne. A heathen reaction was beginning to show itself in several of the English states—Kent, East Anglia, and Essex. In this movement P. saw a chance of Mercia freeing itself from the overlordship of the Christian kingdom of Northumbria, and allying himself with the Cymric prince Cadwallon, he attacked and slew Eadwine (q. v.) at Hatfield in 633. Nine years later he defeated and slew Oswald, the successor of Eadwine, at Maserfield. P. now stood supreme in England. Northumbria alone stubbornly resisted his overlordship, though year by year he wasted the land in ruthless invasions. Nor could he extirpate Christianity, or daunt the courage of its missionaries. Everywhere they were at work, and his power was quietly undermined in spite of his valour and craft. His own son, whom he had made king of the Middle English, received baptism from the monks of Lindisfarne. At last the extension of Northumbrian influence along the eastern coast stirred the aged monarch to a fresh, and, as it proved, a final struggle. In his eightieth year he marched against Oswi, the Northumbrian king. The two armies met at Winwidfield, by Leeds, in 665. P. was utterly routed, and fell along with thirty men of kingly family. 'The river over which the Mercians fled was swollen with a great rain; it swept away the fragments of the heathen host, and the cause of the older gods was lost for ever.' See Bede's *Hist. Eccl. Gent. Angl.*; *The English Chronicle*; and Green's *History of the English People* (1877).

Pen'dant, in later Gothic and Elizabethan architecture, an ornamental piece of stone or timber depending from a roof or vault. On stone vaulting the pendants are sometimes very large and richly carved. Of these, Henry VII.'s chapel at Westminster contains fine specimens.

Pen'dant, or **Penn'ant**, a long, narrow, tapering flag carried at the main-mast head of a ship of war to show that she is commissioned. The *Broad P.* is a square piece, carried (in the same way) on a commodore's ship. The *Rudder P.* is a rope fixed by a chain to the rudder, to prevent it from being lost when unshipped.

Penden'tive (from Lat. *pendere*, 'to hang'), in architecture, that portion of a groined or vaulted ceiling which, springing from the capital of any pillar, is enclosed by the longitudinal and transverse arches, and bounded by their apexes.

Pen'dleton, a suburb of Manchester, 2 miles distant on the mainroad to Bolton, also a station on the W. section of the Lancashire and Yorkshire railway. It is a part of the borough of Salford, to which municipality it has belonged since 1852. On the Eccles Old and New Roads leading W., many villas have been erected by Manchester merchants. The pop. has increased rapidly of late years from the great development of the industries of cotton and flax-spinning, calico-printing, and dyeing. In the vicinity are extensive collieries. Pop. (1871) 25,489.

Pen'dulum is any body which oscillates under the action of gravity about one of its points which is fixed. A heavy mass or *bob* suspended from a point by a light rod or string is the ordinary form of simple P., and is the simplest form under which the peculiarities of P. motion can be studied. Suppose then a sphere of weight, *W*, suspended from a fixed point by a thin rod, whose weight may be neglected, compared to that of the bob; and let the distance from the point of suspension to the centre of the sphere be represented by *l*. This distance is the length of the P., since the mass of the bob may be regarded as concentrated at its centre of inertia, which is in this case its centre of figure. For any P. the point at which the mass may be regarded as concentrated is called the centre of oscillation. The condition that the P. should be in stable equilibrium is that the centre of oscillation should be vertically below the centre of suspension. When this condition is fulfilled, a displacement of the bob to either side will call into existence a force tending to bring it back again; and if this force be permitted to act without restraint, the P. will return to its mean position and continue to oscillate about it. If the arc of oscillation is small compared to the length of the P., the motion is very approximately simple harmonic motion, and the P. is nearly isochronous. That is, the time of oscillation through different lengths of arc is the same, provided the arcs are all small. It is given by the formula:—

$$T = 2\pi \sqrt{\frac{l}{g}}$$

when π is the constant 3.14159....., and *g* is the acceleration due to gravity in one second. Hence the time of one half-oscillation or the beat of the P. is equal numerically to

$$\pi \sqrt{\frac{l}{g}}$$

Here it is observed that mass does not enter. In other words, the material of which the bob is composed does not affect the time of oscillation. This was experimentally proved by Newton, and clearly demonstrates that the weight of a body—i.e., the attraction of the earth upon a body—is proportional to the mass of the body. And hence every body is equally accelerated under the action of gravity. A glance at the formula, which gives the time of swing of a P., suggests at once an experimental method for calculating this acceleration. Squaring both sides of the equation

$$t = \pi \sqrt{\frac{l}{g}}$$

and transforming, there results the equation

$$g = \frac{\pi^2 l}{t^2}$$

where, of course, *g* is expressed in the units of length and time chosen. When the foot and second are taken at Edinburgh, *g* = 32.207; when the centimetre and second are employed, *g* = 981. Or, in words, at the end of each successive second, the velocity of a falling body is accelerated by 32.2 feet, or 981 centimetres. Any body which, like the simple P., has one degree of freedom (oscillation, namely, in a given plane, and therefore about a definite axis perpendicular to the plane), is similarly isochronous for small oscillations. If the moment of

inertia of the body about the axis of suspension be divided by the product of the whole mass into the distance of the centre of inertia from the same axis, the quotient represents the distance from the axis of a point, known as the centre of oscillation. Its property is that if the whole mass were collected there, the simple P. so formed would oscillate in the same time as the body does. The centres of oscillation and suspension are interchangeable—a property which at once suggests an experimental method of determining the position of the centre of oscillation. The method was successfully applied by Captain Kater in his determination of the length of the second's P.

The greatest number of degrees of freedom which a P. of invariable length can have are two, since this condition of invariable length confines the bob to a definite spherical surface. Such a P. is generally termed a conical P., since the connecting sweeps out the surface of a cone, whose vertex is the point of suspension. The path traced by the bob, being the intersection of a cone by a sphere whose centre is at the vertex, is therefore a spherical conic, which for particular cases assumes extremely simple and interesting forms. If the P. is so suspended that the time of oscillation is the same in every azimuth, the cone described is one of the second order, and therefore for small oscillations the path of the bob is in general an ellipse. If the times of oscillation in two mutually perpendicular planes differ, the path is no longer so simple; but if this difference be small, the path may be regarded as an ellipse, which, however, is continually varying in eccentricity, passing through all possible forms, from a straight line to a circle.

The most important practical application of the P. is to the regulation of timepieces. In its simplest form a clock P. consists of a light metal rod with a flat circular bob attached below. Above, it communicates by means of the escapement with the clock-train, in such a way that at every beat of the P. each wheel suffers a certain definite rotation round its axis. There is therefore a particular time of beat required to make the clock keep accurate time. For this time of beat a certain length of P. is necessary. Should the P. be too long, the time of beat will be lengthened, and the clock will go slow; and if the P. is too short the clock will go fast. By a fine screw adjustment the bob can be raised or lowered according as the clock is going fast or slow. When, however, the P. is finally adjusted to the proper length, another cause of error arises from the variation of this length with temperature. An increase of temperature necessarily lengthens the P., and slackens the time, while a decrease in temperature quickens the time. To remedy this, Harrison invented his *gridiron* P., and Graham his *mercurial* P. The principle of the former is shown in the cut. The rod is composed of alternate bars of two different metals. The outside bars and the centre bar are of the same metal, and when heated expand *downwards*. The intermediate bars are made of the other metal, and when heated expand *upwards*. The coefficients of linear dilatation for these two metals are different; but the lengths of the bars are so proportioned that the whole lengthening downwards of the one set is exactly counteracted by the whole lengthening upwards of the other, so that the bob is not altered in position. In Graham's compensation P., the bob is a glass cylinder containing a quantity of mercury. When, through rise of temperature, the single metal rod lengthens, the mercury in the cylinder simultaneously expands upwards, and raises the centre of inertia of the bob; and hence, by using a proper quantity of mercury, the centre of oscillation is kept at a constant distance from the centre of suspension. See *HORLOGY*.

Penel'ope, daughter of Icarius and Periboea, according to the Grecian legend embodied in the *Odyssey* of Homer was the wife of Ulysses (q. v.) and the mother of Telemachus. During the long absence of Ulysses after the Trojan war, she was surrounded by a crowd of eager suitors, but constantly put off their advances with the excuse that she must first weave a shroud for Laertes, her father-in-law, and to extend the time she used to pull down at night what she had woven during the day. This practice, however, having been detected, she was forced to name a day on which to choose between the rivals, when the timely arrival of her long-wandering husband rewarded her constancy and saved her reputation.

Pen'guin (*Aptenodytes*), a genus of *Natatorial* birds, belonging to the *Alcida* or Auk family. The hinder toe is small, and the bill slender, its base being covered by skin. The wings are very short, and covered with rudimentary or scale-like feathers. They are useless for flight, but aid the bird in swimming and diving. The front toes are webbed. The legs are short, and being placed far back on the body, enable the P. to rest in an erect posture, on the long *tarsus* or ankle. The bones are heavy as compared with those of most other birds, are destitute of air cavities, and contain marrow; conditions which give the birds a secure hold of the water. The penguins are strictly aquatic, inhabiting sea-coasts, particularly in southern latitudes, and assembling in immense numbers. They may be seen on some coasts presenting a serried array, and looking like files of soldiers drawn up in regular line. The female hatches its eggs by keeping them between its thighs, and moves about with them in this position. It usually lays a single egg, and the young are covered with a grey wool. The common P. (*A. pennantis*) is a familiar species, but the King P. (*A. pennanti*) is one of the most typical forms. The latter attains a length of 3 feet. The head and throat are of a black colour, and encircled by a yellow band. The back is grey, with a bluish tint, and the under parts are silvery white. This species is common on the Patagonian coasts, as is also the crested P. (*Eudyptes chrysocoma*).

Pen'holders are numerous in form and varied in material, but they are most commonly made of pencil cedar. Messrs. Joseph Gillott and John Morrison in 1859 patented a most ingenious machine for automatically making, polishing, and varnishing P. from rods or strips of wood supplied to it. Much ingenuity has also been expended, without any considerable advantage, in designing fountain P. intended to carry in them a supply of ink.

Penin'sula (Lat. *pene*, 'almost,' and *insula*, 'an island') a portion of land nearly encircled by water, and connected with the mainland by an isthmus.

Penis, the term applied to part of the male organs of generation in animals, the P. being the copulatory organ. It is found in many Invertebrates (e.g., some insects, molluscs, &c.), and may be wanting in some vertebrata (e.g., fishes, &c.). In mammalia it is attached to the *Symphysis pubis* (see PELVIS), and consists, in the human subject, of a body, root, and glans. The root is attached to the pubis by two fibrous processes, the *crura*, and by a fibrous membrane termed the *suspensory ligament*. The body of the organ is covered by a very thin integument, which at the glans or extremity becomes folded on itself, to form the *prepuce* or *foreskin*. The mucous membrane covering the glans is unprovided with sebaceous glands, but its surface is covered with *papillæ* which are highly sensitive. The substance of the body consists of erectile tissues, capable of undergoing distension when filled with blood. These tissues are disposed in three chief masses, of which the two *corpora cavernosa* are the chief, the *corpus spongiosum* forming the remainder of the organ. The corpora cavernosa lie side by side and form the upper portion of the P., whilst the corpus spongiosum encloses the *urethra*. Each of the former bodies consists of a strong envelope of fibrous tissue, containing erectile tissues. The corpus spongiosum is also erectile in its nature, and in addition contains a layer of muscular fibres. The *veins* of the P. are very numerous, and form the chief elements in the erectile tissue. They are largest in the middle of the corpora cavernosa, and open into the *dorsal vein* of the P. The *arteries* are derived from the *internal pudic branch*, and the nerves from the *internal pudic nerve* and *hypogastric plexus*.

Penitential Psalm, or Psalm of Confession, was a name applied in the early Church to the Fifty-first Psalm, which was regularly used as a general confession of sin at the close of daily morning service. It is now applied to seven—Ps. vi., xxxii., xxxviii., li., cii., cxxx., cxliii.; the number having probably been fixed with reference to the days of the week.

Peniten'tiaries are properly asylums for penitent women. The first institution of the kind in this country was the London Magdalen Hospital founded by Mr. Dingley in 1758. The condition of admission was penitence, not destitution. For fifty years the Magdalen was the only house of refuge for the fallen, and long claimed to restore permanently two-thirds of all those received within its walls. In its palmyest days 300 applicants were treated

annually, but the average of recent years has been under one half of that number. From its establishment till 1st January 1877, 10,867 women have been admitted, of which number 7119 are stated to have been reconciled to their friends or placed in service; 2402 discharged at their own request, and 1106 discharged for improper conduct. The number of cases dealt with in the Home at Streatham during the year 1876 was 141. The period of an inmate's probation is about two years, during which she is trained in laundry and needle-work, and prepared for service, and receives general and religious instruction. The proportion who remained till they were passed into service was 65 per cent. of the whole a quarter of a century ago, but has now decreased to about 42 per cent. At the end of a year a former inmate receives £1. 1s. if she is still doing well, and as a matter of fact about one-fourth come to claim this reward. The apparently less successful results of the Institution during the latter half of its existence may be greatly owing to the increased demand all over the country for domestic servants, which makes a situation now more easily obtainable by those women who sincerely wish to change their mode of life, while on the other hand many of the impenitent avail themselves of the home at times of absolute destitution. There is nevertheless abundant proof that in many instances the good work done is crowned with success. There are now a multitude of similar institutions all over the country, whose rules and regulations as to discipline and length of probation vary to a large extent. The Church Penitentiary Association had in 1877 in union with it 21 P. and 13 Houses of Refuge, in which 149 self-devoted women were ministering to an average of 753 penitents. Out of 1032 who left during the year, 489 cases were recorded as favourable, 197 as unfavourable, and 346 as doubtful. The Reformatory and Refuge Union, founded in 1857, had also a large number of P. in connection with it. The London Female Penitentiary was established in 1807, and up to 1877 had received 5333 inmates, of which 1830 had been placed out to service, 1067 reconciled and restored to their friends, and 965 had been discharged at their own request. The number of inmates average from 70 to 80. Seven Homes with accommodation for 170 inmates were in connection with the London Female Preventive and Reformatory Institution in 1878. Among the leading provincial P. are the Magdalen Hospitals at Dublin (founded 1767), Edinburgh (1797), and Glasgow.

Penitentiaries were instituted by 19 Geo. III. c. 7. They are now regulated by the Prisons Act. See REFORMATORY and INDUSTRIAL SCHOOLS.

Peniten'tiary, in the early Church, was a priest whose office was to receive private confessions, in order to facilitate and promote the exercise of public discipline. It was not long, however, till the office was abolished, on account of scandal. In modern times the name is applied to a court at Rome, as well as to the president (generally a cardinal), the business of which is the consideration of cases calling for dispensations (from penance, &c.) from the Pope.

Penn, William, son of Admiral Sir W. Penn, was born in London, 14th October 1644, and received his education at Chigwell in Essex, in Ireland, and at Christ Church, Oxford. In the last place an incident occurred which turned the whole current of his life. He heard the new gospel of Quakerism preached by Thomas Loe, became infected by its republican spirit, gave up attendance on the English Church, resented the wearing of academical robes, and even attacked fellow-students to whom they had not become obnoxious. His enthusiasm resulted in expulsion from Oxford, and earned for him the strong disapproval of his father, who at first declined to see him, but afterwards equipped him for a trip on the Continent so as to win him back to sense and worldly wisdom. The experiment was not successful, for after two years' residence in France and Italy, P. returned to England, studied at Lincoln's Inn until 1666, when, being despatched to Ireland to look after some family estates, he again met Loe and resumed his former connection with Quakerism. Again his father was disgusted with him on his return to England, and when the obstinate sectarian declined to uncover either in the presence of the Duke of York or the King, the admiral drove him a second time from his door. Though P. immediately commenced to preach and publish, the paternal heart again softened towards him. But in 1668 he was sent to the Tower for an attack upon the Trinity contained in *The Sandy Foundation Shaken*. It was followed by *No Cross, No Crown*;

Innocency with Her Open Face, and two other books, all written during the eight months of his confinement. He resumed preaching as soon as he was set at liberty, and (1670) was summoned before the magistrates; but the jury declined to convict him, and were themselves fined. In the same year died Admiral P., leaving his son £1500 a year and claims on the Government for £16,000. Imprisonment for six months (1671) resulted in his publication of the *Great Cause of Liberty of Conscience*. After a propagandist tour on the Continent in the company of Fox and Barclay, he married (1672) a daughter of Sir W. Springett. Meanwhile his attention was being directed to the New World, where the Friends were already forming themselves into colonies for the purpose of obtaining liberty of worship and equal political rights. He became a proprietor (1677) in W. New Jersey, which was partly constituted a Quaker settlement. With the intention of founding an exclusively Quaker colony he got a grant of land in 1680 from Charles II. as a quitclaim of the £16,000 due to him, between Maryland and New York. He had power to make laws with the assent of the freemen, and, curiously enough, command of the forces. In 1681 he followed the three ships which had already crossed with colonists, drew up rules for the settlers, and in 1682 published a constitution and laws. His laws, which only enacted religious conformity to the extent of belief in one God, were marked by a large spirit of tolerance. To him also was due the foundation of a lasting friendship with the Indians. Stress of business in 1684 sent him back to England, and upon the accession of James II., his father's friend, he became a visitor at Whitehall, which led to his being denounced as a Papist and a Jesuit. His connection with the court has furnished Macaulay with certain heavy charges which he has brought against him of conspiracy, falsehood, and Jacobitism. That there was some ambiguity in his behaviour both then and afterwards with regard to the Stewart family may be admitted; but it is now universally allowed that the strictures of Macaulay are not only too severe, but in at least one particular case absolutely unjust, the historian having recklessly confounded P. with his brother. Under William III. P. was thrice accused of treason, but acquitted after a searching trial in 1693. He was married a second time in 1695, and in 1700 he revisited his colony, where disputes had broken out. He returned to England in 1701; and in 1712, being embarrassed in his circumstances, offered his proprietorship for sale to the crown, but failed to agree about the terms. Being seized with a stroke of apoplexy, he became quite unfit for business. He died at Ruscombe, Berkshire, 30th July 1718. Whatever be the true explanation of his relationship to James II., P. has earned an undying character for love of liberty; and he is known to have been a conscientious and just administrator. His *Complete Works* were published in two vols. fol. 1726. See H. Dixon's *Life of P.* (1851); Paget's *Inquiry into the Evidence of the Charges brought by Lord Macaulay against W. P.* (1858); Macaulay's *History of England* (1849-55); and *Correspondence between P. and Logan, Secretary of Pennsylvania, and Others, from Original Papers* (vols. i. and ii.; Lippincott, 1874). A literary curiosity, entitled *Facsimile Copies of Original Letters, Deed, &c.*, by William and Hannah P., was published by direction of Mr. Samuel Gurney (Lond. 1877).

Pennair, or **Pinakini** ('the bow of Siva'), the name of two rivers in S. India, both of which rise near Nundidrug in Mysore, and flow E. into the Bay of Bengal. (1) The north P. falls into the sea about 19 miles below Nellore town. Total length, 355 miles. Area of drainage basin, 20,500 sq. miles. It is useless for navigation, being liable to heavy floods, which in 1874 carried away an important railway bridge. At Nellore ferry an *amcut* or weir was constructed in 1857, and repaired in 1869 by Sir A. Cotton. It is now capable of irrigating 64,000 acres. The canal of the Madras Irrigation Company, completed in 1871, connects the P. with the river Krishna. (2) The south P. falls into the sea a few miles from Cuddalore. Total length, 245 miles. Area of drainage basin, 6200 sq. miles. In the upper portion of its course the water is collected in large reservoirs for irrigation.

Pennant, Thomas, D.C.L., F.R.S., a naturalist and antiquary, descended from an old Welsh family, was born at Downing, Flintshire, 14th June 1726. He was educated at Queen's and Oriel Colleges, Oxford, and early devoted himself with ardour to the study of natural history. In 1761 he published the first part of his *British Zoology*, which gained him

a solid reputation both in Britain and on the Continent. Four years afterwards he visited France and Germany, where he became acquainted with Buffon, Haller, and Pallas. In 1769 he made a tour to Scotland, which he revisited in 1771, and where he met with a distinguished reception. After a busy life of research and literary labour, he gave to the world in 1793 an amusing work entitled *The Literary Life of the late T. P., Esq., by Himself*. He died 16th December 1798. P.'s chief works are *British Zoology* (1761-69), *Synopsis of Quadrupeds* (1771), *Genera of Birds* (1773), *Arctic Zoology* (3 vols. 1784-87), *Tours in Scotland* (3 vols. 1790), *Tour in Wales* (2 vols. 1778-81), *Account of London* (1790), *Outlines of the Globe* (2 vols. 1800).

Pennat'ula, or '**Sea-Pen**,' so named from their resemblance to a quill-pen, a genus of *Calenterate* animals, class *Actinosea*, and order *Alcyonaria*. The organism consists of a main stem, the lower and dilated extremity of which is implanted in the mud or sand of the sea bed. A slender rod-like coral structure is found in the interior of the stem at its lower portion—this coral being of the *sclerobasic* variety. The main stem supports lateral branches, and the little 'polypes,' each having eight fringed tentacles, are born on the branches. P. occur round the British coasts, and may attain a length of from 2 to 4 inches. One species (*P. phosphorea*) is markedly phosphorescent at night. The name 'Cock's-comb' has been applied to species of P. which are nearly related to the *Virgularia* (q. v.) or 'sea-rods.'

Pennon, in Heraldry, a small flag with either one or two points. Borne on the lance, immediately below the head, the P. was considered the peculiar ensign of knightly rank, was charged with the bearer's badge, and was usually fringed with gold. The charges on the P. were so placed, that they were in position when the lance lay level for the charge. A lesser flag of the same kind was called a *pennoncelle*.

Pennsylvania, one of the States of the American Union, and of the original Confederacy of 1776-88, is bounded N. by Lake Erie and New York, E. by New York and New Jersey, from which it is separated by Delaware River, S. by Delaware, Maryland, and W. Virginia, and W. by W. Virginia and Ohio. Area, 46,000 sq. miles; pop. (1870) 3,521,951, of whom 65,294 were coloured. The State is in form almost quadrangular, its boundaries on the N., W., and S. being merely the lines of longitude and latitude. Its surface is much diversified, and is traversed from N.E. to S.W. by the Alleghany ranges, which here reach a breadth of more than 100 miles, though none of the summits attain a height of 3000 feet. To the W. of these lies a broad plateau, which occupies half the area of the State, and is only occasionally broken by ranges of low hills, while the eastern portion of the State displays an alternation of broad valleys and gently rounded hills, not less suited for the growth of cereals than the more level land in the W. The principal rivers are the Delaware, Susquehanna, Monongahela, and Alleghany, the two latter uniting at Pittsburg to form the Ohio. The chief geological formations are the Silurian, Devonian, and Carboniferous, which are overlaid in most districts by a thick bed of alluvial deposit, and interrupted by isolated masses and ridges of trap rock. The most valuable minerals worked in P. are anthracite coal (in 1870, 25,000,000 tons), iron (in 1873, 1,389,573 tons), petroleum (in 1875, 8,619,639 barrels), zinc, copper, marble, and slate. One-fourth of the area of the State is covered with forests, which are infested by bears, panthers, lynxes, wolves, and other wild animals. In 1874 there were 17,994,200 acres of the land in farms, valued at \$1,043,481,582. In the same year the produce of Indian corn was 35,821,000; of oats, 25,607,000; of wheat, 16,636,000; of buckwheat, 2,062,000; of rye, 3,250,000; of barley, 437,000; of potatoes, 9,223,000; of tobacco, 10,500,000 lbs.; and of hay, 2,421,900 tons—total value, \$117,730,915. The live stock comprised 573,700 horses, 722,600 oxen, 828,800 milch cows, 1,674,000 sheep, and 930,900 swine—total value, \$121,803,698. P. imports grain, dairy produce, cloth, and machinery; the chief articles of export being coal, iron, and petroleum. In the amount of its manufactures the State is second only to New York. In 1870 the capital invested was \$406,821,845, and the value of annual produce \$711,894,344. The chief manufactures are iron, machinery, flour, leather, cotton (in 1870 nearly 140 mills), woollens (in 1871, 457 factories), sugar, and glass. In 1877 there were 5983 miles of railway, and nine canals, with

a total length of 875 miles. The State debt in 1876 amounted to \$23,233. Harrisburg is the capital, and Philadelphia the largest city; other towns of importance are Pittsburg, Alleghany, Scranton, and Reading. Delaware River was first ascended in 1616 by Cornelis Hendricksen. In 1643 a colony of Swedes settled at Tinicum Island, and founded several towns, which were taken forcible possession of by the Dutch under Stuyvesant in 1655, but came into the hands of the English on the conquest of New Amsterdam by the latter in 1664. In 1681 the territory of P. was granted by Charles II. to William Penn, in consideration of the claims of his father, Admiral Penn; and the province remained in possession of the Penns till the reading of the Declaration of Independence at Philadelphia, July 4, 1776, in which year its constitution as the State of P. was drawn up and ratified. In 1778 the original charter was annulled, and the Penns were allowed £130,000 for their unsettled lands in the State. Slavery was abolished in 1780. Great excitement was created by the discovery of petroleum in 1859, and P. still remains the chief seat of its production. In July 1877 alarming riots took place in the State, arising out of a great strike on the railways and in the collieries, which were only suppressed, after many excesses, by the troops under General Hartman. The damage done to railway property was estimated at £2,000,000. Much ill-feeling was left behind, and a 'working-men's party' was formed outside the two great recognised divisions (Republicans and Democrats) in American politics.

Penny (Old Eng. *pening* and *penig*, Ger. *pfennig*, Icel. *penningr*, 'cattle,' 'money'), a copper coin of English currency, equivalent to the twelfth part of a shilling, and the 240th part of a pound sterling. Originally it was a silver coin, and was the only one current before the Norman Conquest. Until the reign of Edward I., the P. was deeply indented with a cross, so that it could be easily broken into two for *half-pence*, and into four for *farthings*. The weight of the P. was also at this time fixed as the twentieth part of an ounce—hence the *pennyweight*, one of the weights of Troy measure. The first copper P. was struck in 1797, though copper halfpennies and farthings had been in use since 1672. The P. of the present day is of much smaller dimensions than the original copper coin, and weighs when new half-an-ounce. The halfpenny is exactly an inch in diameter.

Pennyroyal. In some of the English counties this plant is in such request for flavouring purposes amongst the poorer community as to be now almost eradicated. In others it is universally grown in cottage gardens, and made into a herb tea (see MINT). American or mock P. (*Hedeoma pulegioides*) is also a labiate herb with a pungent pleasant taste. It is common in the United States, and is extensively used there in domestic medicine.

Penobscot, the largest river of Maine, U.S., rises near the centre of that State, and, after a southerly course of nearly 300 miles, flows into the Atlantic at P. Bay. It is navigable for large vessels to Bangor, 60 miles from its mouth, where the tide rises 17 feet. The P. is the most important salmon-stream in the United States.

Pen'rith (Cymr. *Penrhyn*, 'the head of the ford'), an old market-town of Cumberland, picturesquely situated at the base of Beacon Hill, in a rich valley to the S. of Inglewood Forest, near the rivers Lowther, Lamont, and Petterill, 17 miles S.S.E. of Carlisle by rail. It has the ruins of a castle, a large parish church of 1720, a church in 13th c. style erected in 1850, a free grammar-school founded in the reign of Elizabeth, a literary institute, &c. The industries are brewing, ironfounding, and timber-sawing. P. is a tourist starting-point for the English Lakes, and in the vicinity are Broughton Castle, and many other interesting remains. The Beacon Hill commands delightful views of Helvellyn, Ullswater, Skiddaw, and Saddleback. Pop. (1871) 8317. P. was sacked by the Scots in the reign of Edward III., and again in that of Richard III.

Pen'ryn (Cymr. 'the headland'), a market-town of England in Cornwall, at the head of Falmouth Harbour, 2 miles N.W. of Falmouth by rail. It has a town-hall, market-house, mechanics' institute, one newspaper, granite and manure works, tanneries, flour, paper, and saw mills, and large warehouses for grain and other imports. Fishing and boatbuilding are the principal industries, and there is a considerable export trade in granite and vegetables. P., with Falmouth, returns two members to Parliament. Pop. (1871) 3679.

Pens (Lat. *penna*) are instruments employed to produce written characters by means of fluid ink. The earliest form of P. appears to have been made from a species of reed, such as is still in use in Persia, Arabia, and China. The quills of various large birds, especially the goose and the swan, were of later introduction, being unknown till about the 5th c. These constituted the P. in general use among modern civilised communities till the present generation, when steel P. were introduced, and these have now greatly superseded all other forms, although the demand for quills is yet very considerable. A steel pen was invented and manufactured by a Mr. Wise about the year 1803, but as it was both costly and inefficient, it met little success; and the first who secured a patent for making steel P. was Mr. James Perry, in whose specification, dated 24th April 1830, the modern steel pen is clearly described. The 'Perryan' P. were manufactured by the late Sir Josiah Mason of Birmingham, to whom along with the late Joseph Gillott is due the perfection to which the modern metallic pen has reached.

Birmingham has a practical monopoly of the pen manufacture, none being made anywhere else in the United Kingdom, while in foreign countries the manufacture is on a comparatively unimportant scale. The industry affords a healthy employment for females; and the Gillott factory, for beauty of machinery, tidiness, and general air of comfort, is one of the most pleasing and interesting sights in the whole range of industrial pursuits. The following is an outline of the processes necessary for the production of a steel pen:—The steel must be of the finest quality, and is received in ribbons of about 3 feet in length, and of such a breadth that the blanks for P. may be cut out, leaving the least possible amount of 'scrap' or waste. The strips are first annealed, and the scale formed on them is removed by pickling in dilute sulphuric acid, and they are passed between rollers to bring them to the necessary thickness for pen-making. The 'blanks' or pieces which form the pen are next cut out, two blanks with insculcating points being cut out of one breadth of steel ribbon. In these blanks the side slits which give elasticity to the point are first cut, the hole which terminates the slit subsequently made is next pierced, and at this stage the blanks are annealed in a muffle furnace. The maker's name or any special mark is next impressed on the blanks, and they are now ready for being rounded or rasped into pen form, which constitutes the next operation. At this stage the P. in process are packed in a small iron box heated in a muffle, and hardened by plunging into oil. The P. are next tempered, after which they are polished or scoured by being mixed with polishing material, and placed in a revolving cylinder, in which they are brightened by the attrition of the revolving material. The points have now only to receive attention, and they are first ground straight or parallel to the axis of the P., then cross ground, and as a final operation the central slit is made. The finished P. require only to be blued or browned and varnished, and the colouring is done by heating them over a charcoal fire till they assume the desired tint, the varnish consisting of lac dissolved in naphtha. The manipulative processes indicated above are performed with hand-screw presses, fitted with the requisite piercing, cutting, or bending tools, and worked by girls—self-acting machinery being but little employed. For many years Birmingham has produced annually from eight to fifteen million gross of P. Thirty years ago P. were sold wholesale at 5s. a gross, and now they are sold as low as 1½d. and 1¼d. per gross. When it is remembered that each gross requires 144 pieces of steel to go through at least 12 processes, the fact that 144 P. can be sold for 1½d. is a singular example of the results attainable by the division of labour and mechanical skill. P. are manufactured of other substances besides steel. Of these, the chief are gold P., which possess the advantage of being incorrodible by ink, besides having a fine quill-like flexibility. Gold P., tipped with a native alloy of osmium and iridium (osmiridium) are exceedingly durable. In the United States there were in 1876 some thirty factories of gold P. and pencils, producing goods to the value of nearly \$2,000,000 yearly. P. of silver, platinum, and aluminum bronze are also manufactured, and they may be similarly tipped with osmiridium.

Pensacola, a town in the W. part of Florida, U.S., on P. Bay, 10 miles from the Gulf of Mexico, and 160 miles S.S.W. of Montgomery by rail. It has an excellent harbour, protected by several forts, and considerable trade in lumber. Pop. (1870)

3347. P. was a place of some importance under the Spaniards, and near the town are the ruins of their fortresses San Miguel and San Bernardo. Held by the French from 1719 to 1723, it passed to England in 1763, was recovered by the Spaniards in 1783, and was again occupied by the English during the war of 1814. It was ceded to the United States, October 24, 1820. P. suffered severely during the civil war of 1861.

Pensionary, Grand. See GRAND PENSIONARY.

Pensioners, Military and Naval.—(1.) *Pensions to Officers.*—The highest class of pensions in the army are those called 'Rewards for Distinguished Services.' In 1877-78 the amount in the estimates under this heading was £33,530, being £21,700 pensions to officers (£100 each with few exceptions), £5000 to sergeants, £830 Victoria Cross pensions, and £8000 gratuities for long service. The corresponding 'Meritorious Services' pensions in the navy were estimated in the same year at £7400, being at the rate of £300 to flag officers, £150 to captains, and in various amounts to marine and medical officers. £240 was paid in pensions 'for conspicuous bravery.' *Pensions for wounds* are awarded by the Secretary of State for War to officers in the army, and by the Lords of the Admiralty to those in the navy, who have suffered serious injuries while on active service. From £400 to a lieutenant-general to £70 to a lieutenant is paid when wounds are equivalent to a loss of a limb, so long as the effects of the wound continue, and gratuities of from three to twelve months' pay of the ranks is granted for less serious wounds. The amounts on this account (1877-78) were £15,097 to 164 officers in the army, and £8265 to 83 officers in the navy. Ninety old and disabled officers in the navy received £5025. The Government also charges itself with *Pensions to Widows* of commissioned and warrant officers so long as they remain unmarried, provided that their husbands were sixty years of age (fifty if warrant officers) when they married, and that death occurred at least twelve months after marriage. These pensions are of three classes, according as the death of the officer has been occasioned, (1) in battle, or from wounds, death occurring within six months, (2) by some cause arising from his duty, (3) by the ordinary course of nature. In the first class they range from £60 to the widow of a lieutenant to £200 to the widow of a lieutenant-colonel or of a captain in the navy, in the second class from £50 to £150, in the third class from £40 to £120. Allowances are also sometimes made to sisters of deceased officers who are dependent upon them. In the army (1877-78) 1821 widows received pensions of £106,126. In the navy, 235 widows and relatives of slain or drowned officers received £13,374, 2604 widows of deceased naval officers £131,972, and 170 widows of marine officers £8898. When the families of the deceased are in distressed circumstances, 'compassionate allowances' are made on account of the children, varying from £5 to £40 each, and payable till the child attains the age of eighteen if a boy, or twenty-one if a girl. Charge for compassionate and royal bounty allowances in the army (1877-78) £37,035, in the navy £18,500. (2.) *Pensions to Men.*—Soldiers in the army become entitled to long-service pensions after twenty-one years' service, or a shorter period in case of wounds or disablement. So small pensions as 1½d. a day are granted to negro soldiers in the W. Indies, but the amount to soldiers in this country is 8d. a day to a private, and 2s. 6d. to a non-commissioned officer, with an addition of 1d. a day for every good-conduct badge held by the pensioner on his discharge. In certain cases pensions for wounds are granted, the maximum to a non-commissioned officer being 3s. 6d. A soldier discharged at the end of twelve years, his first period of service, is entitled to no pension; but he may enlist again for a further period of nine years. If he has been discharged as an invalid, or because he is unfit for service, he receives a temporary or permanent pension varying from 6d. a day to the ordinary amount. Gross misconduct takes away the right to a pension. In all the important towns there are staff-officers of pensions, who pay the amounts to the old soldiers in their respective districts. In 1878 there were five of these staff-officers in London, two in Plymouth, and fifty-seven in other towns, the expenses of this department being £60,000. The cut-pensions in the army (1877-78) amounted to £1,345,200, £340,000 of which was charged to India. This includes the payment of 68,234 Chelsea P., and allowances to native P., and Maltese Fencible Artillery P. Gratuities to well-conducted soldiers on

and after their discharge from the army were provided from the fund arising from fines for drunkenness to the extent of £17,000. The in-P. are housed at Chelsea Hospital, London, and Kilmainham, Dublin, and receive small pensions (privates 7d. per week, corporals, &c. more), and board, lodging, and clothing. The expense of Chelsea Hospital, including pay of 538 inmates, was estimated (1877-78) at £28,400; that of Kilmainham, which accommodates about 130 P., at £6612. Pensions to seamen and marines in the royal navy are similar to those in the army, and are payable through the military staff-officers of pensions. They vary from £3 to £57 a year, and the total amount estimated in 1877-78 was £477,285 to 21,036 recipients. There have been no naval in-P. since the transformation of Greenwich Hospital to a naval college. Small pensions are granted to mercantile sailors from the funds of Trinity House. A detailed history of pensions in the British army to the year 1869 will be found in vol. ii. of the *Military Forces of the Crown*, by C. M. Clode.

Pentacrinus, a genus of *Crinoids* (q. v.) or sea-lilies, represented by the *P. Caput-Meduse* of the Caribbean Sea. Each P. consists of a starfish-like body, supported on a flexible-jointed stalk. It is rare as a living organism, though plentifully represented in a fossil state. The lists of living species, however, have been considerably extended within late years through the discovery of new species made by deep-sea dredging expeditions. The stalk in P. is pentagonal, and bears lateral processes. The genus P. occurs fossil in Mesozoic rocks, *P. fasciculosus* of the Lias being a familiar species. The calyx is short and the arms are slender and branched.

Pentadesma, a genus of *Guttifera*, to which belongs the butter or tallow tree of tropical W. Africa, called by botanists *P. butyracea*. It grows to the height of about 40 feet, and bears a large pear-shaped fruit containing a yellow oily juice, which is used by the natives as an article of food, notwithstanding its strong turpentine flavour. P. must not be confounded with Mungo Park's Shea butter-tree, for which see *BASSIA*.

Pentagon (Gr. *pente*, 'five,' and *gōnia*, 'an angle') is a plane geometrical figure of five sides.

Pentail, a remarkable species of *Insectivorous quadrupeds*, scientifically known as the *Phlcornus Lowii*. It inhabits Borneo, and derives its popular name from the length of its tail, which is hairless except at its tip, where rows of stiff hairs are developed on either side, after the fashion of the barbs on the sides of a feather. The hairless portion of the tail is scaly. The P. attains the size of a small rat. Its colour is a blackish-brown above, and a yellowish-grey beneath. The tail is black, the feather-like tip white.

Pentamera (Gr. *pente*, 'five,' and *meros*, 'a part'), one of the subdivisions of the order *Coleoptera*, or that of the beetles. The P. has five joints in the *tarsi* or feet.

Pentastoma (Gr. *pente*, 'five,' and *stoma*, 'a mouth'), a genus of lower *Arachnids*, allied to the mites, &c., and forming the type of the order *Linguatulina* or *Pentastomida*. P. (or *Linguatulina*) *tenoides* is a familiar species inhabiting the liver and lungs of herbivorous mammals in a sexless state, and attaining sexual and mature development in the frontal sinuses of dogs and other *Carnivora*. The body is worm-like, the mouth being surrounded by a horny ring. The sexes are distinct, and the females are larger than the males.

Pentateuch (Gr. *hē pentateuchos*, scil. *biblos*, 'the five-volumed book') is the Alexandrian name for the first part of the Jewish Scriptures, the Thorah ('Law'), or so-called five books of Moses, which is one connected historical work beginning with the creation of the world and extending to the death of Moses.

History of Criticism.—The universal opinion in ancient times, both among Jews and Christians, was that the whole work was written by Moses. Yet, even in the 2d c., this was called in question by some of the heretical sects. Among Jewish scholars of the Middle Ages, two at least expressed doubts on the same subject. Aben Ezra (q. v.), who quotes Isaak ben Jason (11th c.) as maintaining that Gen. xxxvi. 31 was written in the time of Jehoshaphat, without agreeing with him, and without questioning the Mosaic authorship of the P. as a whole, held that such passages as Gen. xii. 6, xiii. 14, Deut. i. 1, iii. 11, xxxiv. were later additions. During the 16th c. and 17th c. various writers expressed the opinion, with various modifications, that although Moses may have written part of the P., in its present form it

was the work of a much later age—that of Samuel, David, or the Captivity: Carlstadt (*De Canon. Script.* 1520); Masius (*Com. on the Book of Joshua*, 1574); Hobbes (*Leviathan*, 1651); Peyrerius (*Syst. Theol.* 1655); Spinoza (*Tractatus Theologico-Politicus*, 1670); Clericus (*Sentimens.* 1685); and Dale (d. 1708). During the 18th c. the principal writers on the subject were on the other side, seeking to fortify the view of the Mosaic authorship; Carpozov, Eichhorn, and Michaelis in their Introductions (1721, 1782, and 1787). But at the end of the century the old doubts and objections began to be expressed again. This was done by Hasse (*Views for the Future Explanation of the Old Test.* 1785); F. C. Fulda (*The Age of the Holy Scriptures, &c.* 1791); H. Corrodi (*Attempt at an Inquiry, &c.* 1792); Otmar (Nachtigall, *Fragments, &c.* 1795); and Eckermann (*Theol. Contributions*, 1796), much in the same way as previous scholars had done. In the beginning of the present century Vater (*Com. on the P.* 1805); Augusti (*Introd.* 1806); and De Wette (*Introd.* 1806, 1807), endeavoured to prove, in a more complete way than had hitherto been done, that Moses could not be the author of the P. At the same time other writers maintained the Mosaic authorship generally, or only admitted some later additions and interpolations: Hug (*The Art of Writing among the Hebrews, &c.* 1801, and *Hist. of the Samaritan P.*); Kelle (*Unprejudiced Estimation, &c.* 1811); Meyer (*Apology, &c.* 1811); Fritzsche (*Exam. of the Grounds, &c.* 1814); Jahn (*Contributions, &c.* 1818, 1819); Kanne (*Bibl. Investigations, &c.* 1819, 1820); Rosenmüller (*Schol. in P.* 3d ed. 1821); Puskuchen (*Hist. Crit. Investigation, &c.* 1823); Staudlin (*Authenticity, &c.* 1825); Sack (*Christian Apology, &c.* 1829); R. Graves (1815); Hartwell Horne (*Introd.* 1818). Other writers on the conservative side, while not claiming the whole P. for Moses, ascribed to him an important share in its composition: Bertholdt (*Introd.* 1813); Volney (*Researches, &c.* 1814); Herbst (*Observat. de P. &c.* 1817); Eichhorn (*Introd.* 4th ed. 1823). Another class of writers succeeded, who denied to Moses any share at all in the composition of the P., which they held to have been compiled gradually after the time of Samuel, great part of the contents being mythical: Hartmann (*Investigations, &c.* 1831); Von Bohlen (*Genesis Elucidated, &c.* 1835); Vatke (*Bibl. Theol.* 1835). On the other side the literary unity and Mosaic authorship of the P. was maintained against all objections by Ranke (*Investigations, &c.* 1834-40), Hengstenberg (*Introd.* 1836-39), B. Bauer (*The Mosaic Origin, &c.* 1836), Movers (*Disc. of the Book of the Law, &c.* 1834-35), Drechsler (*Inaccuracy, &c.* 1837, *Gen. is.* 1838), König (*Old Test. Studies*, 1839), Welte (*The Post-Mosaic Matter in the P., &c.* 1841), Havernick (*Introd.* 1837-49). The most recent investigators are Stahelin (*Crit. Investigation, &c.* 1843), De Wette (*Introd.* 5th and 6th ed. 1840 and 1845), Ewald (*Hist., &c.* 2d ed. 1853), Von Lengerke (*Canaan, &c.* 1844), Keil (*Introd.* 1853), Knobel (*The Books of Numbers, &c.* 1861), Black (*Introd.* 2d ed. 1865), Colenso (*The P. Examined, &c.* 1862-71), Kalisch (*Com.* 1800-72), Davidson (*Introd.* 1862), Graf (*The Hist. Books, &c.* 1866), Kuenen (*The P. Crit. Examined, &c.* 1863; and *Rel. of Israel, &c.* 1874), the compilers of *The Speaker's Commentary* (1871).

Authorship.—The principal objections brought forward by critics to the received theory of the Mosaic authorship are the following:—1. Passages which seem to imply events or circumstances of a later date; e.g., Gen. xii. 6, xiii. 7 would seem to have been written when the Canaanite and the Perizzite were not in the land; xxxvii. 31, in the time of Saul, at the earliest; xiii. 18, xxiii. 2, xxxv. 27 (*cf.* Josh. xiv. 15, xv. 13), Ex. xvi. 35 (*cf.* Josh. v. 12), Lev. xviii. 24-28; Deut. i. 1, ii. 12 not before the time of Joshua, when the people were settled in Canaan; Gen. xiv. 14 not before the time mentioned in Ju. xviii. 29; and Deut. iii. 11, 14 (*cf.* Num. xxxii. 41, and Ju. x. 3, 4), xxxiii. 1, and especially xxxiv. could not have been written by Moses. 2. 'The Book of the Wars of Jehovah' (Num. xxi. 14), which could not have been composed before the end of the journeyings in the desert, would not likely have been quoted by Moses. 3. Some of the laws cannot with any likelihood be ascribed to Moses; e.g., (1) the ordinances regarding kings (Deut. xvii. 14-20), who were not included in the original constitution; (2) Deut. xix. 14, 20 presupposes the settlement in Canaan; (3) Ex. xxii. 29, 30, that the people have already brought first-fruits to the priests; (4) xxiii. 19, the existence of the sanctuary; (5) Lev. xxvi. 3-45, a state of things which did not exist till the later period of the kings. 4. The repetitions which occur (1) in the

giving of the laws, not merely in Deuteronomy, but, e.g., the precepts in Ex. xxxiv. 17-26, given before in xxi.-xxiii., and that in xxii. 20 repeated xxiii. 9; various precepts in Lev. xx. given before in xviii.; (2) in the historical parts—e.g., the sending of the quails (Ex. xvi. 12, 13, and Num. xi.). Similar repetitions appear in Num. xx. 1-13 (*cf.* Ex. xvii. 1-7), ix. 15-23 (*cf.* Ex. xl. 34-38), Ex. vi. 2-vii. 7 (*cf.* iii.-v.). 5. Discrepancies in various laws; e.g., the two ordinances that the service of the Levites was to begin at the age of thirty (Num. iv. 47) and at twenty-five (viii. 23-26), and the two that the Levites were to be supported by the tithes of the people (Num. xviii. 20-32), and that they should receive a tithe every third year while the regular tithes were to be consumed in feasting (Deut. xiv. 22-29); and the two copies of the Decalogue (Ex. xx., Deut. v.). 6. An indication of composite authorship is found in the unnatural arrangement of many of the sections; e.g., the genealogy of Moses and Aaron in Ex. vi. 14-27, which seems out of place in the context, and to show by its title, contents, and conclusion, that it was drawn up without any special reference to Moses and Aaron. The visit of Jethro to Moses (Ex. xviii.) presupposes that the people had reached Sinai (*cf.* v. 5, 'at the mount of God'), whereas their arrival is only related in xix. Again, all the time that elapsed between the giving of the instructions for the making of the tabernacle (Ex. xxv.-xxxi.) and its completion, according to xl. 2, 17, was nine months, which seems far too short for the work. Besides, in xxxiii. 7-11 there is an account of a 'tabernacle of the congregation,' which was pitched by Moses without the camp as a sanctuary, without any reference to any other, or to its being merely temporary. Further, the account presupposes the census as already made (Ex. xxxviii. 25, 26), which was only ordered to be made in the following month, Num. i. 1). In Lev. xxiv. 5-9, the ordinance regarding the shew-bread is repeated, which had been given in Ex. xxv. 30, and in xl. 4 presupposed as already well known. 7. Cases of disjointed chronology; e.g., the ordinance for the keeping of the Passover, given on the first month of the second year (Num. ix. 1), ought to have come before the account of the census (i.-iv.). 8. The great chasm in the history of thirty-eight years is considered even by moderate critics to be a very serious objection to the Mosaic authorship. According to Num. xx. 1, the people arrived at Kadesh in the first month (which must be) of the third year (*cf.* Deut. ii. 14), and at v. 23 there is given the account of the death of Aaron at Mount Hor, as if that event had happened immediately after; whereas, according to xxxiii. 38, it did not happen till thirty-eight years afterwards. 10. Perhaps the strongest indication of composite authorship is found in certain peculiarities of language, specially observable in Genesis, which have given rise to the distinction of the Elohistic and Jehovistic narratives, a distinction originally founded on the exclusive use in different passages of Elohim or El (God) or Jehovah (Lord) as the name of the Almighty, but by no means resting on this alone. On the contrary, it is demonstrated that the series of passages forming what is considered to be the original narrative differ from all the rest of Genesis by the presence in them of a variety of verbal peculiarities as striking as is the difference, e.g., between the style of Addison and that of Johnson. 11. Although the art of writing was probably known to the Hebrews in the time of Moses (*cf.* Ewald, *Gesch.*, vol. i.), it seems more probable that any record of events written by a contemporary would have been a bare chronicle, such as is actually preserved in Num. xxxiii. 1-49, than a work of such extent as the P. Having regard to the above particulars, the conclusion has been arrived at even by conservative critics that, while there are considerable portions of the P. as old as the time of Moses, he did not compose the whole of it, but that it is, at any rate as we now have it, the product of a much later date. (See the articles on the separate books.) Irrespective of the critical objections enumerated above, there is no antecedent improbability that Moses wrote the last four books, which are a record of the events of his own time. As regards the Book of Genesis, or the history from the creation, the customary explanation of how he wrote it is that he was enabled to do it by inspiration, but the popular idea of inspiration may perhaps require to be modified by the recent discoveries of Chaldean literature, from which it appears that before the time of Moses, the stories contained in the first nine chapters of Genesis had a place in Chaldean mythology. See Smith's *Dict. of the Bible* (1863), Davidson's *Introduction* (1800), Ewald's *Geschichte d. Volkes Isr.*, vol. i. (Eng.

trans. 2d ed. 1869), Rawlinson and M'Caul, in *Aids to Faith* (1862), Bleek's *Einleitung in der A. T.* (Eng. trans. 1869), Smith's *Chaldean Account of Genesis* (Lond. 1876).

Pentecost (Gr. *pentēkostē*, scil. *hēmēra*, 'fiftieth day'), is the Greek translation of the later Jewish name of the Feast of Weeks (Exod. xxxiv. 22, cf. 2 Macc. xii. 32; Acts. ii. 1), which was so called because celebrated seven weeks after the Passover (Lev. xxiii. 15, 16), also called the Feast of Harvest (Exod. xxiii. 16), the Day of First-fruits (Num. xxviii. 26), &c. The time fixed for the celebration of P. was the fiftieth day from the morrow after the Sabbath of the Passover (Lev. xxiii. 11, 15-21), or from the 16th of Nisan. Originally observed purely as a harvest festival, the later Jews connected it with the giving of the law by Moses, which, as they deduced from Exod. xix., must have taken place on the 6th of Sivan. The festival is observed by the Jews to the present day on the 6th or 7th of Sivan. In the Christian Church, P. was early observed as the Festival of the Holy Spirit (cf. Acts ii.), but the name was applied to the whole period of seven weeks between Easter and P. It was the special season for administering baptism, and as all the Catechumens (q. v.) were baptized in a white dress, the last Sunday of P. got the name of Dominica in Albis, and in England that of Whitsunday. See Ginsburg in Kitto's *Cyclo. of Bib. Lit.* (3d ed. Edinb. 1876).

Pentland (a corruption of 'Pictland') **Firth**, a strait which separates the Orkney Islands from the mainland of Scotland, and connects the North Sea with the Atlantic, is 24 miles in length and from 12 to 15 miles in breadth, extending from Duncansby Head to Dunnet Head on the S., and from S. Ronaldshay to Hog Islands on the N. It has from 10 to 40 fathoms of water, and it is calculated that upwards of 4000 vessels pass through it annually. A strong current flowing from W. to E. at the rate of from 5 to 10 miles an hour renders navigation dangerous. At the eastern outlet lie the Pentland Skerries, two small islands, on one of which stands a lighthouse; and near the middle, opposite Scalpa Flow, are the islands of Stroma and Swoma. To the W. of Stroma are the breakers called 'The merry men of Moy,' which roll unceasingly even in the finest weather; and on the N. side of the same island there is a large eddy caused by the current, called 'Swalchic.' There is an anchorage in Gill's Bay, a few miles W. of Duncansby Head.

Pentland Hills, a range of hills in Scotland extending S. W. for about 12 miles through the county of Edinburgh to the borders of Lanark, in three ridges, with a mean height of 1000 feet. The highest summits are Scalt Law, or the Sisters (1898 feet), near which is Glencorse Reservoir, and Carnethy (1890 feet), on the E. slope of which is Rullion Green, where the Covenanters were defeated by General Dalziel, 28th November 1666. The rocks composing the P. H. are chiefly porphyry or other rocks of the Old Red Sandstone age, but towards the W. and S. Silurian deposits come to the surface. The slopes, 'Pentland's green acclivities,' afford excellent pasture for sheep.

Penumbra. See SHADOW.

Pen'za, a central government of European Russia, to the S. of Nijni-Novgorod, has an area of 14,826 sq. miles, and a pop. (1870) of 1,173,186. It is a wide fertile plain, varied with a few low hills, and watered by the Moksha and Sura, affluents of the Volga. About a half is cultivated, while over one-third is meadow, and there are extensive oak forests. The products are grain, flax, hemp, tobacco, beet-root, and vegetables. The chief towns, besides P., are Mokshansk, Nijni-Lomov, and Saransk. —P., the capital of the above government, lies on the Sura, 350 miles S.E. of Moscow by rail. Founded in 1666 as a defence against the Tartars, it has 19 churches, a great park and fruit-garden, a horticultural school, &c. There are industries in leather, soap, candles, and linen, and an important yearly market. Pop. (1870) 30,462.

Penzance (Cymr. 'the saint's headland'), a seaport of England in Cornwall, 9 miles E.N.E. of Land's End, and 26 S.W. of Truro by rail. Its chief edifices are the Public Buildings (1867), in the Italian Renaissance style, with a façade of 135 feet, and comprising a guildhall, council chamber, library, and museum; the market-house, public baths, custom-house, and a granite tower, erected (1873) as a memorial to Sir Humphrey Davy, who was a native of P. There are two

churches, two banks, and a weekly and a daily newspaper. Situated on Mount's Bay, and within easy reach of the finest coast scenery in England, P., from the mildness of its climate, has become a favourite winter watering-place. Its harbour is protected by a pier (1866), 800 feet long, with a lighthouse at the end. In 1876 there entered 845 vessels of 65,867 tons, and cleared 443 of 31,859. The exports (tin, copper, and fish) amounted to £41,135; the imports (iron, timber, hemp, &c.) to £50,214; and the customs to £4661. P. in 1875 had 97 vessels of 7187 tons, besides 572 boats employed in the important pilchard fishery. Mining and the raising of early vegetables employ a large number of the inhabitants. Pop. (1871) 10,425.

Peon. See CALOPHYLLUM.

Pe'on, a word of most uncertain derivation, adopted by all European nations in India for a kind of civil orderly or footman in the departments of police, justice, and customs. They usually wear an official badge, and formerly bore arms.

Peoria, a city of Illinois, U.S., on the W. bank of the Illinois river, which is here crossed by two bridges, 2500 feet long, is the junction point of nine railways, and is connected with St. Louis by lines of river steamers, and with Chicago and Lake Michigan by the Michigan Canal. It has 28 churches and 5 daily newspapers. The chief manufacture is iron. An expansion of the Illinois river at this point, called *P. Lake*, is 22 miles long and 3 broad, abounds in fish, and in winter yields a large amount of ice. Pop. (1870) 22,849.

Pe'pe, the name of three Italians who played a prominent part in Neapolitan history. Gabriele P. was born in 1781 at Bojano, in the province of Campobasso; his cousins, Floristano and Guglielmo, at Squillace, in Calabria, the former in 1780, the latter on February 15, 1783. They all co-operated in the erection of the short-lived Parthenopean Republic (1799), and on its downfall took service with France, and were enrolled in the Italian Legion. In 1806 they returned to Naples, and held appointments in the armies of Joseph Bonaparte and Murat, which were confirmed by Ferdinand at the Bourbon restoration (1815). Floristano alone of the three did not involve himself in the Revolution of 1820, for his share in which Gabriele endured two years' imprisonment at Olmütz, whilst Guglielmo lived for twenty-eight years a refugee in France and England. Gabriele died in August 1849, and Floristano in 1851. Guglielmo, recalled to Naples by the insurrectionary movement of 1848, received the command of the contingent dispatched to the aid of the revolted Lombards. Disregarding the order of recall, he threw himself with 2000 men into Venice, and after its capitulation retired to Paris, thence to Nice, and finally to Turin, where he died, August 9, 1855. He published, among other works, a *Histoire des Révolutions et des Guerres d'Italie en 1847-49* (4 vols. Par. 1850). A life of his brother Florestano was written by Carrana (Gen. 1851).

Pepin. See PIPPIN.

Pepper (Lat. *piper*, serving as the botanical name of the genus; Gr. *peperi*; Sansk. *pippali*) is the type genus of *Piperaceæ* (q. v.). The most important species is *P. nigrum*, which yields the condiment of daily household use. It is a climbing shrub, with alternate heart-shaped leathery leaves, dioecious or hermaphrodite flowers, followed by spikes of berries about the size of a currant, at first green, and when mature bright red. The plant is a native of the E. Indies, where also it has long been cultivated, and has at various times been introduced into the W. Indian Islands, Trinidad, Borneo, Java, Sumatra, and other tropical countries. In cultivation it is usual to plant cuttings at the base of rough-barked trees, to the trunk of which they attach themselves during growth, and rise to a height of about 12 feet. After three years they produce fruit,

Betel Pepper.

and yield profitable crops annually (about 1½ lb.) for eight or ten years. The 'corns' are gathered when red, and after being dried in the sun they shrivel and change colour, becoming the 'black P.' of the shops. To form what is called the 'white P.' the fruit is freed from its fleshy outer coat by maceration and subsequent rubbing. From ancient classical writers we learn that P. was held in high esteem in very early times, and for a long period it remained one of the most costly of spices. At the present day it forms a large and important item of commerce. To some extent P. is used medicinally as a hot aromatic stimulant and tonic, and is occasionally employed externally as a rubefacient. It owes its pungency to about 2 per cent. of an essential oil, and contains about 2½ per cent. of a tasteless crystalline substance called *piperine*. The compact fruit-spikes of *P. Roxburghii* (something like those of the common British plantain used for pet birds), when sun-dried, form the 'Long P.' It is extensively cultivated in many parts of India. *P. tricinum*, another Indian species closely allied to *P. nigrum*, furnishes a very pungent fruit, forming part of the P. of trade. Betel P. (q. v.) and Cubeb P. (q. v.) are also the products of species of *Piper*, or of genera recently separated therefrom.

The name P. as an affix is further applied to numerous vegetable products irrespective of their botanical right to it. Thus, in *Solanaceæ*, we have bird P., cherry P., spur P., and bell P.—forming cayenne P.—for different species of *Capsicum*. In *Magnoliaceæ* there is the P. plant of Tasmania (*Tasmannia aromatica*); in *Anonaceæ*, the Guinea P. (*Xylofia ethiopica*). In the English flora *Sedum acre* (*Crassulacæ*) and *Polygonum Hydropiper* (*Polygonacæ*) are respectively called the wall and water P. from their biting taste and places of growth.

Medicinal Properties of P.—The dried unripe berries of the *Piper nigrum* are used in medicine as a warm, carminative stimulant. P. acts on the mucous membrane of the rectum and urethra, and is useful in hemorrhoids and gonorrhœa, in doses of from 5 to 20 grains. P. is contained in *Confectio opii*, and *Pulvis opii compositus*. *Confectio piperis*, prepared from black P., caraway, and clarified honey, is given in doses of from 60 to 120 grains.

Peppermint. See MINT.

Pepperpot is a W. Indian appetising preparation consisting of cassareep, capsicum, ochio, sliced cucumbers, very fine chopped shallots, Madeira wine, and other ingredients, with flesh or dried fish, and is resorted to by those affected with loss of appetite or weak digestion.

Pepper-Root is a name applied to *Dentaria diphylla*, a N. American cruciferous plant with a curious toothed creeping rootstock, which has a pungent mustard-like taste, and is used as a condiment by the natives, hence it is also sometimes called Indian mustard.

Pepsine is a preparation of the mucous lining of the fresh and healthy stomach of the pig, sheep, or calf. The cleansed mucous membrane is scraped off with a blunt instrument, and the viscid pulp thus obtained is immediately spread over the surface of glass, or glazed earthenware, and quickly dried at a temperature not exceeding 100°. The dried residue is then reduced to powder, and preserved in a stoppered bottle. P. is given in cases of indigestion from deficient or imperfect secretion of gastric juice, and in convalescence from debilitating fevers. The dose of the powder is from 2 to 5 grains.

Pepusch', Johann Christoph, a German musician, born at Berlin about 1667, settled in England in 1700, and after an engagement at Drury Lane Theatre became a teacher of music. He received the degree of Mus. Doctor from Oxford in 1713. He wrote the overture and set the music to Gay's *Beggar's Opera*, and published a treatise on *Harmony* (1731). P. died in 1752, and was buried in the Charter-House, of which he had been organist for fifteen years.

Pepys, Samuel, son of a tailor, was born at Brampton, Huntingdoushire, February 23, 1632, passed his early life in London, and received his education at St. Paul's School and the University of Cambridge. As an undergraduate he is reputed to have been a 'fast' man, an entry in his college register still preserving the record of an admonition 'for having been scandalously over-served with drink ye night before.' In his twenty-third year he married a penniless beauty of

fifteen, and in 1658 he obtained a clerkship of the Exchequer. He was soon elevated, owing to the aptitude he showed for business, to the clerkship of the Acts. Having attracted the attention of the Duke of York, Lord High Admiral, P. retained this position until 1673, and the arrangement of the entire navy was in his hands during the exciting events of the Plague, the Fire of London, and the Dutch War. During the agitation in connection with the Popish Plot, P. was briefly confined to the Tower on suspicion. Recalled to the Admiralty, he retained his place until the Revolution, when he retired into private life. He died of stone, 26th May 1703. P.'s title to fame rests wholly upon the contents of his *Diary*, a series of private jottings extending from January 1659 to May 1669. It was discovered among a collection of books and prints bequeathed by him to Magdalene College, Cambridge, and published in 1825, under the editorship of Lord Braybrooke. A sixth edition, in 4 vols., appeared in 1858. The *Diary* was originally in shorthand, which was successfully deciphered (1819-22) by the Rev. John Smith, M.A., afterwards promoted to the rectory of Baldock, Herts. As P. entered all the experiences of each day, the book remains one of the most interesting sources of allusion to persons, events, and manners given to posterity by that century. The Rev. Mynors Bright learned the cypher in 1872, and subsequently transcribed the whole MSS. He published a new edition of the *Diary and Correspondence*, with the life and notes by Lord Braybrooke, numerous portraits from the collection in the Pepysian library, and additional notes (vols. i. and ii. 1876). This edition contains about one-third more matter than was ever before published—contains, indeed, 'the whole *Diary*,' to use Mr. Bright's words, 'with the exception of such parts as I thought would be tedious or that are unfit for publication.' 'When he wished to keep anything particularly concealed,' P. wrote his cypher generally in French, sometimes in Latin or Greek or Spanish. Afterwards he changed his plan, and put in *dummy* letters. It is disappointing to hear that all passages written in this manner are quite unfit for publication, and that their perusal has in no way contributed to P.'s good fame.

Pera ('beyond'), a suburb of Constantinople, on the N. side of the Golden Horn, opposite old Stambul, with which it is connected by a floating bridge. It crowns a bold promontory, and is the foreign diplomatic quarter, and the chief residence of the 'Franks.'

Perak', or Perah', a petty state in the Malay Peninsula, extending for about 70 miles along the W. coast, separated from Queddah on the N. by the Krian river, and bounded E. by a mountain range. In the S. are alluvial valleys producing rice and tobacco, and also valuable mines of tin. The interior is mountainous and overgrown with jungle. The chief means of communication is by the P. river. In 1874, owing to disturbances caused by the immigration of Chinese tin miners and by a disputed succession to the throne, it was resolved by General Sir W. Jervois, the governor of the Straits Settlements, to establish a British Resident at P., and to espouse the cause of Sultan Abdullah. Mr. Birch, a former colonial secretary at Singapore, was appointed the first Resident. On the occasion of his posting up a proclamation announcing that British officers would henceforth administer the state, he was murdered by the party of the dispossessed Sultan Ismail in November 1875. To avenge this outrage a military detachment from Singapore, reinforced by a Gurkha battalion from Calcutta, advanced up the P. river under the command of General Colborne, and a naval brigade gave valuable co-operation. After slight losses unavoidable in jungle fighting, the murderers of Mr. Birch were at last killed, and Sultan Ismail surrendered himself prisoner in March 1876. The state of P. has since been tranquil under British administration, and a loan has recently been issued in London to pay the cost of the petty war, and to open up the country. It is hoped by the merchants of Singapore that this event will lead to the extension of British protection over the entire peninsula of Malacca. See *P. and the Malays* by Major Macnair (London, 1878).

Perambulation of Parishes. See BEATING THE BOUNDS.

Perception is the mind's apprehension of an external world by means of the organs of sense. It is the linking of subject with object. Sensations are recognised as pertaining to self and yet not self. The self is under perfect control; sensations are

not. Individual sensations cannot be created or destroyed at will, but are passively received by the thinking subject. Our knowledge of external things may be resolved into sensations of different kinds which are grouped together in our minds, projected into space, and supposed to be united in objects existing independent of the perceiving mind. Thus what in the mind are sensations become, outwardly, qualities of a hypothetical substance. The child soon learns to associate together the sensations of heat and cold given by touch and the sensation of resistance to muscular effort, when these repeatedly and simultaneously occur. If, by and by, a certain sensation of colour be felt as an invariable concomitant of these other sensations, it is also associated with them; and coldness, hardness, and blueness—let us say—are transferred from the organs of sense and the mind to something external, of which we term them qualities. Sensation and quality are supposed to be correlatives, one in knowledge, the other in existence. In the one case, sensation appears to be a sign suggesting quality; in the other case, the quality is looked upon as that which causes the sensation.

P. proper is a higher act of intelligence than sensation—is, indeed, educated sensation; but sensation is its *sine qua non*. It is further evident that the simplest act of P. must involve, not merely recognition of an external object, but, as a prerequisite to this, an affirmation of self-existence:—consciousness declares, 'I am,' and then, 'Something not myself exists.' A vain attempt has been made in certain systems to refine upon this analysis by discriminating between the cognition, 'I know,' and the cognition, 'I know that I know,' as acts of separate faculties. The scholastic dictum well affirms the unity of this knowledge—*Non sentimus, nisi sentiamus nos sentire; non sentimus nos sentire, nisi sentiamus*. The following eight conditions, according to Hamilton, are partly common to P. and the other acts of consciousness, partly proper to P. as a special operation:—(1) A certain concentration of consciousness on an object of sense—*attention*; (2) a *plurality, alteration, difference* between the perceived object and the perceiving subject; (3) *quality*; (4) *time*—memory supposed; (5) *space*; (6) *degree*; (7) *relation*; (8) *assertory judgment*—that within the sphere of sense an object exists, and exists thus and thus conditioned.

It is difficult to discover formulated theories of P. in ancient philosophy. The writings of the Greek sages were equally psychological, cosmological, theological, ethical, political. But the thread running through the whole of ancient philosophy is dualism, the antagonism of matter to mind. Idealism proper is of comparatively recent development, Plato's 'ideas' notwithstanding. We have a couplet of Epicharmus that indicates a pretty clear knowledge of the principal fact of P.—

'Mind it seeth, mind it heareth;
All beside is deaf and dumb.'

Plutarch mentions a treatise of Strato Physicus, designed to prove 'that a sensitive apprehension is wholly impossible without an act of intellect.' But however accurately the ancients defined the problem, it was reserved for modern philosophy to attempt its systematic solution.

The philosophy of Descartes was the philosophy of doubt. Everything that could be doubted he resolved to reject; and so he abandoned the existence of the world, of God, of his own body, of all but self. Self remained. To doubt is to think; to think is to be a thinker; '*cogito ergo sum*.' Here was the foundation of P. From the imperfection of the thinking being, and its innate idea of P., he deduced the existence of God. But the thinking being has other ideas than that of perfection, of God; these he cannot summon or destroy at pleasure: yet they are distinct from God; therefore they must be caused in the thinking being by God. One of these ideas is that of extended substance; accordingly, unless God deceive us, extended substance must exist. To point out the fallacies of this system, or any other, is beyond the scope of this article.

Malebranche developed the doctrine of Descartes. Descartes could only bridge the gulf between matter and mind by means of what amounted to a divine revelation. Malebranche accepted his position. The soul is immaterial, the external world is material; they have nothing in common by which they may be known to each other. The soul derives its ideas neither from itself nor from things, but from God. 'We see all things in God.'

Spinoza started with the Cartesian definition of substance as that which, for its existence, stands in need of nothing else. Accordingly, Spinoza argued, there can be but one substance,

and one existence—no dualism. Everything that appears to differ from the ideal substance must be one of its 'attributes'—thought and extension, or one of its 'modes'—individual, finite, evanescent forms. This all-pervading substance is God.

But this explanation did not suffice. Why should thought and extension of necessity exclude one another, even as different attributes of the same substance? Locke, the founder of modern materialism, explained the ideal in the material. He banished all innate ideas, and derived knowledge from experience alone. Instead of drawing reality from the mind, he draws it from the external world, of which mind is the mirror. '*Nihil est in intellectu quod non fuerit in sensu*.'

Berkeley's position was the opposite of Locke's—he explained matter in mind. Leibniz had prepared the way for him. Sensations, he said, are altogether subjective. Distance and form are not even sensations, but are mere inferences from sensations. Things only exist in a percipient mind; their *esse* is *percepti*. 'There is not any other substance than spirit, or that which perceives.'

Hume's sceptical philosophy was the natural result of the systems of Locke and Berkeley. For Hume, knowledge was a bundle of sensations, which have no necessary connection one with another. Alarmed at such a result, Reid fell back upon common sense. According to him, the sensations of the physical organism necessarily suggest external qualities, and by our constitution we cannot but believe in their existence.

Kant dug deeper. All our knowledge begins with experience, but does it arise in experience? We have *à priori* elements in knowledge. By means of sensation we have an intuition of phenomenal objects. *Matter* is that in the phenomenon which corresponds to the sensation; *form* is that which brings the content of the phenomenon under certain relations. The matter of phenomena is given us *à posteriori*; the form is *à priori*. The two conditions of intuition are space and time.

Hume and Kant represent the two existing schools of thought. The one school explains P. upon a theory of association. 'Objects are clusters of sensations supposed to have a permanent existence independent of the individual mind, in consequence of their mutual coherence and regular concurrence.' They are, according to Mill, 'permanent possibilities of sensation.' The other school holds to *à priori* intuitions as the basis of our knowledge.

Perceval, Spencer, Right Hon., second son of the Earl of Egmont, born in London, 1st November 1762, studied with distinction at Harrow and Cambridge, and was called to the bar in 1786. He soon surmounted his natural timidity, and got into good practice. In 1796 a pamphlet upon the impeachment of Warren Hastings, in which he argued that the process was not annulled by the dissolution of Parliament, brought him under the notice of Pitt. He was shortly returned to Parliament for Northampton, which he represented after three separate dissolutions, and gave himself earnestly to a study of finance. In 1801 he became Solicitor-General in the Addington Ministry; in 1802 he was appointed Attorney-General. On the return of Pitt to power he vehemently defended the war with France. In 1807 he was made Chancellor of the Exchequer, with the emoluments also of the Duchy of Lancaster. Two years later, on the death of the Duke of Portland, he rose to be Prime Minister, and under the regency wielded immense power. On the 11th of May 1812 he was shot, when entering the House of Commons, by a Liverpool broker named Bellingham. P. was an industrious and successful but not a great statesman.

Perch (*Perca fluviatilis*), a well-known Teleostean freshwater fish, the type of the family *Percide*. The scales are *ctenoid* or comb-like, and the *operculum* or gill-cover is armed with spines. The teeth are large and numerous, and are situated on the palate and other portions of the mouth in addition to the jaws. The ventral fins are on the breast below the pectorals. The genus *Perca* has from 13 to 15 spiny rays in the dorsal fin; the head is scaleless above. The P. is found in freshwater ponds and rivers, and attains a weight of from 2 or 3 to 5 or even 8 lbs. It is of a greenish-brown hue on the back, but the sides are marked with bands of darker colour; the first dorsal fin is brown, the second of a paler colour. The tail and pectoral fins are bright red. The P. is very voracious, and its flesh is nutritious and palatable. It is caught by different sorts of bait, has considerable vitality, and will live out of water for considerable

periods if the gills are kept moist. The sea-P. is another name for the Basse (q. v.). The giant P. is the *Lucioperca sandra*, and is found in German lakes and rivers. It may attain a length of 2 or 3 feet; its colour is a greenish olive marked with brown stripes. The scarlet P. (*Holocentrum rubrum*) is found in tropical seas, and is of a red colour, variegated with white bands.

Perch. See ROD.

Percola'tion (from Lat. *per*, 'through,' and *colo*, 'I strain') is a process used in pharmacy for the extraction of certain soluble ingredients of various substances by filtering a liquid through them. Many of the tinctures of the British Pharmacopœia are directed to be prepared by P., an operation which requires to be performed with great care that the tincture may be of the standard strength. The process is thus described by Mr. Squire in his *Companion to the British Pharmacopœia*: 'After the materials have been macerated for forty-eight hours in three-fourths of the menstruum ordered, P. will be most efficiently performed by decanting the liquid, pressing the ingredients in the hand, and carefully packing them, in small portions at a time, in a conical percolator, so that the mass shall be uniformly tight throughout. The decanted liquid may then be poured upon the ingredients and suffered to percolate; the remainder of the menstruum being afterwards poured upon them in order to chase the strong tinctures out. As soon as the liquid ceases to drop, the ingredients are to be removed and pressed. Any deficiency in the product may be made up by adding more of the menstruum and repeating the pressure.' The author prefers Burton's process, combined with the abstraction of air from the ingredients: 'Thus, tie up the ingredients and suspend *submerged* in the upper part of the liquid, and fit an elastic cap connected with an exhausting syringe to the neck of the vessel. When the air has been thus abstracted from the structure of the materials, and the atmosphere readmitted, its pressure drives the liquid into every part the air had preoccupied, and complete digestion begins, the impregnated liquid constantly falling, by its gravity, allows the fresh liquid to penetrate and continue the exhausting process until finished.'

Percus'sion (Lat. *percussio*, a 'beating' or 'stoking') is the method of eliciting sounds by tapping the surface of the body, the main object being to determine the comparative density of subjacent parts. The nature of the sound may be elicited by striking over the part either *immediately*, as when the chest is gently tapped with the hand or a light hammer, or *mediately*, as when a flat body is placed upon the chest, which is then struck by the finger or the hammer. P. was first employed by Auenbrugger in the middle of last century, and afterwards by Corvisart, but Laennec, who made diseases of the chest his special study, brought it into general use, and this mode of diagnosis is chiefly employed in diseases of the lungs, heart, and abdominal organs.

Mediate P. is the mode almost universally employed, the apparatus being the pleximeter and the hammer. The *pleximeter* may consist of a flat piece of ivory or wood, a piece of indiarubber, or the index finger of the left hand laid flat on the chest. The *hammer* may consist of a piece of whalebone or light stick with a head-piece of indiarubber; of the flat edge of the stethoscope encircled by a piece of indiarubber; of a light thimble covered with indiarubber; or the points of the index and middle fingers of the right hand may be used. The pleximeter being placed flat upon the chest and held close to its walls, is struck perpendicularly, and with gentle or moderate force. The qualities of the sound to be noted are—(1) Amount in intensity of resonance, commonly called clearness; (2) duration of the sound; (3) pitch; (4) volume of sound. The physical conditions which lessen the quantity of air are—(1) Consolidation of lung-substance, as from exudation, tubercle, congestion, or œdema; (2) compression of the lung from fluid in the pleura, or by tumours. The *pulmonary P. note* is the sound elicited by striking on a part of the chest-wall below which lies a considerable depth of lung. This sound depends upon the vibration of the air contained in the tissue of the lungs, and upon the vibrations of the walls of the chest. When this *note* is exaggerated, or of a higher pitch, it is termed *tympanic*, the sound being similar to that obtained by striking the abdomen when the intestines contain air, and is generally caused by an increased quantity of air in the lung-

tissue or in the pleura, as in pulmonary emphysema, or when cavities exist in the lungs, as in pneumo-thorax. *Tubular* sounds are produced when the lung is consolidated, covering bronchial tubes. When the subjacent substance is solid or fluid, the sound is *dull* in proportion to the density and want of elasticity of the part percussed, and indicates effusion of fluid into the pleura (hydrothorax), or inflammatory solidification of the lung tissue (the hepatisation of pneumonia), or tubercular deposition (phthisis). Although the principles of P. are best illustrated in diseases of the lungs, this mode of diagnosis is indispensable in diseases of the heart, liver, abdomen, &c.

Percussion, Centre of. See CENTRE OF PERCUSSION.

Percussion Caps are small caps made of sheet copper into which a small quantity of a fulminating compound, consisting of fulminate of mercury, saltpetre, and sulphur, is introduced. P. C. are employed for exploding the charges of gunpowder in firearms, and for igniting other explosives, especially dynamite, which can only be exploded by percussion.

Per'cy, a Norman family, which came over at the Conquest, and obtained a grant of lands in the counties of York and Lincoln. The third baron, **William de P.**, died early in the 12th c., leaving two daughters, of whom the elder died without issue, whilst the younger married Jocelin of Hennegau, brother-in-law to Henry I. This Jocelin assumed his wife's surname, and was father of the **Richard de P.** who figures among the twenty-five barons appointed to uphold the privileges of the Great Charter. **Henry Lord P.** (created Earl of Northumberland, July 16, 1377) was an adherent of the house of Lancaster, and as such received from Henry IV. the dignity of Constable and a large accession of lands. But the king's refusal to let him ransom the prisoners of Homildon Hill aroused his discontent, and with the foremost of those prisoners, Lord Douglas, his brother Thomas, Earl of Worcester, and Owen Glendower of Wales, he mustered an insurgent army. Falling sick, he intrusted its command to his son, the 'gallant Hotspur,' who was defeated and slain at Shrewsbury, July 21, 1403. P. himself was pardoned, but two years later, engaging in a plot to seat Edward Mortimer on the throne, he had to fly to Scotland, and thence to Wales, and on a rail into England was mortally wounded (February 29, 1408). The second earl fell in the Lancastrian ranks at St. Albans (1455), the third at Towton (1461). **Henry**, the fifth earl (since 1464, when he obtained a reversal of his father's attainder), became an agent of Henry VII.'s extortions, and was killed in a Northumbrian riot (1489). **Thomas P.** forfeited head and lands by his participation in the Pilgrimage of Grace (1536), but under Mary the earldom was restored in 1557 to his son **Thomas**, who also died on the scaffold (August 22, 1572). **Henry**, the eighth earl, died in his bed, but in the Tower of London, and by his own or an assassin's hand, June 21, 1585, and his son **Henry** was long imprisoned for his share in the Gunpowder Plot. The tenth earl in the Great Rebellion sided with the Parliament, but opposed the execution of the king; with the eleventh, **Joscelin P.**, the male line became extinct (May 21, 1670). His daughter, however, had married Edward Seymour, Duke of Somerset, and their son **Algernon** received the title of Lord P. (1722), and of Earl of Northumberland (1749), which on his death (1750) passed to his son-in-law, Sir Hugh Smithson, a Yorkshire baronet. The latter assumed the name of P., was created Duke of Northumberland (October 22, 1766), and was great-grandfather to the sixth and present duke, **Algernon George P.**, who was born May 2, 1810, and succeeded his father, August 21, 1867. Northumberland House, Charing Cross, for many generations the London residence of the Percies, was sold to the Board of Public Works in 1873 for £500,000, to be removed for the construction of the splendid new approach to the Thames Embankment. The Duke spent part of the purchase-money in improving Trafalgar Square.

Percy, Thomas, D.D., born at Bridgnorth, Shropshire, April 13, 1728, entered Christ Church College, Oxford, and graduated M.A. (1753). Having taken orders, he was presented to the livings of Easton Maudit and Wilby, in Northamptonshire (1756), became domestic chaplain to the Duke of Northumberland (1766), and chaplain in ordinary to the king (1769), was promoted to the deanery of Carlisle (1778), and to the bishopric of Dromore, in Ireland (1782), where he died, September 30,

1811. Himself the author of *The Hermit of Workworth*, *The Friar of Orders Grey*, and other poems, P. is best remembered as the editor of *Reliques of Ancient English Poetry* (3 vols. 1765, latest ed. by H. B. Wheatley, Lond. 1876). The ballads in this collection P. drew from private sources, and from the Papyrus, Ashmolean, and national collections. Their text is often grievously 'restored,' and few of them are really ancient, the greater number belonging to the 16th or 17th centuries. But the good wrought by the work in sweeping away current conventionalism, and in opening men's eyes to the fact that English poetry did not begin with Cowley, may be seen by comparing the scant appreciation it met with from Johnson with Wordsworth's language half a century later: 'I do not think that there is an able writer in verse of the present day who would not be proud to acknowledge his obligations to the *Reliques*. I know that it is so with my friends; for myself, I am happy to make a public avowal of my own.' P. also published *Miscellaneous Pieces relating to the Chinese* (2 vols. 1762), *A Key to the New Testament* (1765), a translation of Mallet's *Northern Antiquities* (2 vols. 1770), &c.

Peregrine Falcon (*Falco peregrinus*), a species of *Falconidae* or Falcons (q. v.), inhabiting both hemispheres, and attaining a length of from 16 to 18 inches. The colour is an ashen brown above, the head and back of the neck being dark brown. The breast is white tinged with chestnut, and the under parts are greyish-white, the whole plumage being marked with bars of dark tint. The eggs are three or four in number, and are reddish brown. The bird was formerly much in request in the sport of Falconry (q. v.). The male is termed a *Tercel*, and the female the *Falcon*, *par excellence*. The term 'Lanner' (q. v.), which properly denotes a distinct species of falcon (*Falco Lannarius*), is also applied to the young P. F. The P. F. is extremely agile and quick in flight, its power of wing being immense, and its muscular strength proportionate. It descends on its prey with a lightning-like swoop, carrying off smaller birds, game, rabbits, and hares in great numbers.

Pereira, Jonathan, M.D., F.R.S., a celebrated pharmacologist and physician, was born in the parish of Shoreditch, London, May 22, 1804. He received a classical education at Finsbury, and then devoted himself to medical studies. In 1823 he was appointed resident medical officer at Aldersgate Street General Dispensary, where three years later he became Lecturer in Chemistry, and in 1832 Professor of Materia Medica. His *Elements of Materia Medica and Therapeutics* (1839-40) contains the result of his long-continued investigations on these subjects, and is still a standard authority. Its plan and execution at once established the scientific reputation of the author. In 1840 he took his doctor's degree at Erlangen, and in 1845 became a Fellow of the College of Physicians. From the establishment of the London University, he was Examiner in Materia Medica and Pharmacy till his death, January 20, 1853. Of P.'s other works, the chief are *A Treatise on Diet* (1843) and *Lectures on Polarized Light* (1843). The last edition of his *Elements* is by Bentley and Redwood (1872).

Perekop (Russ. 'the gate of the headland,' Tartar, *Or-Kapu*), a strongly-fortified Russian town and haven in the government of Taurida, on the isthmus connecting the Crimea with the mainland, 75 miles N. of Sebastopol. It is of some military importance, but its trade in salt and cattle has received a blow from the extension of the Kharkof and Melitopol Railway into the Crimea. Pop. (1870) 4331. The Isthmus of P., 18 miles long, and only 5 broad at its N. end, is an arid sand waste, containing many salt lakes.

Père-La-Chaise. See LA-CHAISE.

Perennial, in Botany. Plants that die after one flowering season are with very few exceptions *Annuals* (q. v.) or *Biennials* (q. v.). If, after flowering, the whole or part of the plant lives through the winter and produces fresh flowers another season, they are P. and may be either herbaceous perennials in which the greater part of the plant dies down after flowering, undershrubs or suffrutescent plants in which the annual dying portion is the flowering branches, shrubs when the perennial woody portion forms the greater part of the individual, but without what is called a trunk, and trees when the trunk is developed and the height considerable. P. herbs often commence flower-

ing the first year, and the same species may be annual or perennial according to climate, treatment, &c.

Perennibranchia'ta ('perpetually gilled'), a name applied to those members of the Amphibian order *Urodela*, which retain the external gills of early life, in addition to the lungs with which they are also provided. Of the P., the Proteus (q. v.), Siren (q. v.), and Axolotl (q. v.) are good examples.

Perslavle-Zalies'ky, a town of Central Russia, in the government of Vladimir, 79 miles N.E. of Moscow by rail. It has 35 churches, and 2 monasteries, one of which, Nikita, is much frequented as a place of pilgrimage. P. has considerable trade, and manufactures cottons, linens, cloth, and silk. Near P. is the Pleshteyevo Lake, where Peter the Great built his first ship. Pop. (1870) 7210.

Perez, Antonio, a Spanish politician, born at Monreal de Ariza, Aragon, in 1539, succeeded his father, Gonzalo P., as secretary of state to Philip II. of Spain in 1567, and long enjoyed the full confidence of the king, though his arrogance and imprudence procured him many enemies. An intrigue which he had with the Princess of Eboli, the king's mistress, being discovered by Escovedo, secretary to Don Juan of Austria, half-brother of the king, P. prevailed upon Philip, whose suspicions had already been aroused by Escovedo's premature return to Spain and the well-known ambitious designs of his master, to give orders for his assassination. It was accomplished in March 1578, and excited a great commotion in Madrid, but P. fancied himself safe from his guilt being shared by the king. However, he was arrested 28th July 1581, and, by an inquiry which terminated January 1585, sentenced to ten years' imprisonment and an enormous fine. The sentence was carried out with the utmost severity, and every means taken to extort from P. the papers which compromised the king. Most of them having been obtained, he was handed over to the authorities on the charge of the murder of Escovedo, but he contrived to escape to Aragon, and went before the court of *Justicia Mayor* of that kingdom. He published in his defence several letters of the king. P. was acquitted by the Court of Aragon; but an attempt being made to reclaim him by the Inquisition, the inhabitants of Saragossa rose in revolt, set P. free, and put to death the Marquis of Almenara, Philip's representative—a procedure which cost them their privileges (*fueros*) and the lives of the principal citizens. In November 1591 P. fled to Bearn, where he was received kindly by Catharine of Bourbon. Philip, after vainly trying to tempt him into Spain, made several attempts to assassinate him, but he fled to Henri IV., and visited England in 1593-95, where he was favourably received by the Earls of Essex and Southampton. In London he published his *Relaciones* (1594) under the pseudonym of Rafael Peregrino. The revelations which this work made still further exasperated Philip, and induced him to make further attempts at his assassination, but the vigilance of P. saved him, while two emissaries were seized and executed at London. He returned to France in 1595, and passed several years at the court of Henri IV., but after the peace concluded between France and Spain at Vervins, May 1598, his services were no longer required. His last years were spent in great distress at Paris, where he died, 3d November 1611. P.'s *Cartas Familiares* and other works are noted for their elegance of style. See Bermudez de Castro's *Antonio P., Secretario del Rey Felipe II.* (Madr. 1841), Mignet's *Ant. P. et Philippe II.* (Par. 1845), and Prescott's *History of Philip II.* (1855).

Perfumery. That the art of P. arose out of the habit of employing incense in connection with worship and religious rites is indicated by the term itself, which is compounded of *per*, 'by,' and *fumum*, 'smoke.' The modern art of P. is concerned chiefly with the application of Essential Oils (q. v.), the substances yielding these, and the compounding of substances possessed of a pleasant odour, for various purposes chiefly connected with the toilet and for incense in apartments or in the service of Roman Catholic and certain of the Anglican Churches. The materials of P. are chiefly obtained from the vegetable kingdom, but some of the most important elements of P. are derived from animal sources, and organic chemistry also supplies several substances extensively employed in inferior perfumes. Although in the vegetable kingdom almost all parts of plants in their turns—roots, stem, wood, bark, leaves, flowers, fruit,

and seed—are found to contain essential oils, and are consequently useful for P., it is principally from flowers that the perfumer draws his raw materials. The P. materials of animal origin are musk, a secretion of the Musk Deer (q. v.), civet, from the Civet Cat (q. v.), Ambergris (q. v.), a morbid secretion of the sperm whale which is occasionally found cast up on continental coasts, and Castoreum (q. v.) from the beaver, the last of which, however, is little used by perfumers. Of artificial essences, that chiefly employed in P. is the essence of mirbane or artificial oil of bitter almonds, which consists of nitrobenzol, a substance very largely made as an intermediate product in the manufacture of aniline from benzol obtained by the distillation of coal-tar. Much of the 'almond soap' sold for toilet use is scented with this perfume.

Several vegetable substances are used for perfuming by merely rasping or pounding, as in the case of highly-odorous woods, leaves, and flowers, and in some cases the materials require to undergo no preparation whatever. But the ordinary perfumes of commerce are 'bouquets' or mixed scents, prepared by compounding various essences or essential oils; and the art of the perfumer is therefore concerned with—1st, the extraction of essences or essential oils from their sources; 2d, the intimate compounding of these so as to produce 'the harmony of sweet smells;' and 3d, the application of these substances to various toilet and other preparations, such as soaps, pomades, dentifrices, &c.

In the extraction of their odoriferous principles from plants, there are four principal methods pursued—1st, Pressure; 2d, Absorption or *enfleurage*; 3d, Distillation; and, 4th, Maceration.

Expression is only available in the cases of a limited number of substances closely allied to each other. These substances are the peel or rind of oranges, citrons, lemons, and other fruits of the orange tribe. From these the essential oil is simply expressed by means of a screw-press; and the exudation, which consists of water and albuminous substances mixed with essential oil, is permitted to settle for some time. The water and albuminoids fall to the bottom, and the essential oil is syphoned off, and when filtered is ready for use. Lemon peel oil is very greatly used in the cheaper forms of P.; but the other citrine oils are more frequently employed as flavouring substances than as perfumes.

Absorption or *Enfleurage* is the method by which the most delicate perfumes of the vegetable kingdom are secured for use. The process depends upon the readiness with which odours are taken up and retained by fatty substances with which they may come in contact. The materials employed for absorbing the odours are purified inodorous animal fats, and fine olive and other oils. Fats impregnated with odours are known as Pomades (Fr. *Pommades*), and the absorption is effected by means of glazed sashes (*Chassis aux Vitres*), thin layers of fat being spread on each side of the glass. Over these the flowers are strewed, and a large number of such sashes are piled above each other, every pair thus making a closed box in which the layers of fat are exposed to the odour of the flowers. The flowers are periodically renewed till the fat is sufficiently impregnated with the odour. In preparing scented oils, similar sashes or frames, having iron network in place of glass, are used, and on these are spread thick cloths which have been steeped in oil. The oil is squeezed out of the cloth after it has been saturated with the odour. From either pomade or scented oil the essential oil may be separated by treatment with spirit of wine 60 over proof, and the resulting alcoholic solution is known as an essence. The substances chiefly treated by absorption are Jasmine (*Jasminum odoratissimum*), Acacia flowers (*Acacia farnesiana*), Tuberose (*Plianthes tuberosa*), Violet (*Viola odorata*), and Wallflower (*Cheiranthus cheiri*).

Distillation.—Although essential oils have a higher boiling-point than water, yet they are distilled over with steam. The distillatory apparatus usually employed contains a perforated false bottom, water being in the lower part, and the vegetable substance to be acted on resting on the perforated bottom; but sometimes water and the oil-yielding body are mixed in the still. The mixed steam and essential oil which distil over are condensed in a worm, and caught in a Florence flask in which the substances settle into two distinct layers, and the oil being almost always specifically lighter than water, floats on the top. The oil separated from the water is rectified by redistillation, and the water itself, which retains a considerable aromatic odour, is utilised in P. as distilled or perfumed water. The

greater part of the strong and less delicately flavoured aromatic oils are obtained by distillation.

Maceration or *Infusion* is a process by which pomades and scented oils are obtained by infusing flowers, &c., in liquefied animal fats, or in heated olive oil, whereby the odours are transferred much more quickly and perfectly to the fat or oil than is possible with the *enfleurage* process. The scented oils or fats may subsequently be treated as indicated for separation of the essences under the absorption process.

A modification of the ordinary processes for extracting essential oils proposed in 1856 by M. Millon has been developed in practice by M. Piver. It consists in treating flowers, &c., with powerful volatile solvents, such as ether, chloroform, or bisulphide of carbon; subsequently distilling off these very volatile bodies, and finally washing the essential oil with water containing a little alkali.

Several of the sweet-scented gum resins and Camphor (q. v.) play an important part in P. The gum resins of importance in incense and as yielding essences are balsams of Peru and of Tolu; Mecca balsam (*Balsamodendron Gileadense*), Storax, Benzoin, Myrrh, and Olibanum. These will be found under their own headings.

In the preparation of 'bouquets' or mixed perfumes the intimate mixture of ingredients is of essential consequence, and a special apparatus is employed to facilitate such blending by agitation. Bouquets are usually very complex in their character, and each manufacturer has recipes which he regards as peculiarly his own. Some preparations have attained great and enduring popularity, such as Cologne Water, Hungary Water, Lavender Water, Jockey Club Perfume, Essbouquet and Millefleurs. In addition to bouquets, perfumers prepare perfume sachets, or small bags of dry perfume, incense, tooth-powders, pomades, hair-oils and hair-washes, toilet soaps, and cosmetics.

The great centre of the industry in essential oils is the Department of the Alpes Maritimes, in the south of France, where flower-farming is a leading industry. At Mitcham, near London, there are also flower-farms for the cultivation of such plants as suit an English climate, and of these lavender is a notable example, English oil of lavender being much finer and more valuable than that produced in Continental countries. See *Piessé's Art of Perfumery* (1855).

Pergamum, or **Pergamus**, an ancient city of Mysia in Asia Minor, was situated near the point where the Selinus and Cætus emptied themselves into the river Caicus. It was 13 miles distant from the sea, with which it had communication by the navigable waters of the Caicus. It is first mentioned by Xenophon, as a fortress of great natural strength (Anab. vii. 8), but remained unimportant until the latter half of the 3d c. B. C., when it was selected as a treasure city by Lysimachus, who intrusted the care of it to the eunuch Philetaerus of Tium. The latter, however, made a successful revolt in 283 B. C., and remained in independent possession of P. for the next twenty years. On his death in 263 the territory descended to his nephew, Eumenes I., who extended its boundaries, and defended it with success against Antiochus. After his death in 241 B. C., he was succeeded by Attalus I. (241-197), Eumenes II. (197-159), Eumenes III. (159-138), and Attalus III. (138-133). The new state was favoured by the Romans as a useful ally against Macedonia and Syria; and at different times was augmented by the addition of Phrygia, Lydia, Pisidia, Lycæonia, and Pamphylia. Meanwhile its capital had become one of the most magnificent cities of Asia Minor. Attalus III., surnamed Philometer, bequeathed P. to the Romans. Under Roman rule the city continued to prosper, so that Pliny could still speak of 'longe clarissimum Asie Pergamum.' Not only did it become the centre of jurisdiction and commerce for the district, but it could also boast of a library second only to that of Alexandria, and its name has passed into the European languages as *Parchment* (q. v.). Under the Byzantine emperors P. sank into insignificance, but it still exists under the name *Bergama* (q. v.), and displays numerous ruins and extensive remains of its former magnificence. P. is one of the seven cities mentioned in the Book of Revelation.

Pergolese, Giovanni Battista, a famous Italian musician, was born at Jesi near Ancona, 3d January 1710. He studied composition at the Conservatorio de St. Onofrio at Naples, under Gaetano Grecco, and his first important work was an oratorio,

San Guglielmo, composed about 1730. His next efforts were operas, in which he adopted a freer and more melodious style than that of the old contrapuntists, the best of them being *La Serva Padrona* (1730) and *L'Olimpiade* (1735). The last-named opera, although subsequently a triumphant success, was a failure on its first production, after which he devoted himself principally to church music. His last great works were *Messa* and *vespers*, a *Stabat Mater* and *Salve Regina*. He died at Pozzuoli, 16th March 1736. In addition to his operatic and sacred compositions he wrote much chamber music, and a large number of instrumental trios. See the *Biografia degli Italiani illustri* (Ven. 1834), and Fétis, *Biographie des Musiciens* (new ed. Par. 1878).

Pergunnahs, The Twenty-Four, a district of Bengal, British India, lying N.E. of the Hooghly river, and enclosing the metropolitan city of Calcutta. Area, 2788 sq. miles, including a large portion of the Sunderbunds (q. v.). Pop. (1872) 2,210,047. The name is derived from the twenty-four fiscal divisions (*parganas*) ceded to the East India Company in 1757 by the Nawauli, Meer Jaffier, which formed the first territorial possession of the British in India. The imperial rights over the same tract were subsequently granted to Lord Clive for life as a *jagheer*. The country is very fertile, and supplies Calcutta with all sorts of agricultural produce and firewood. It is traversed by two railroads, and by many canals and natural watercourses. In 1876-77 the registered exports were valued at £1,644,000, chiefly rice, sugar, firewood, and vegetables; the imports at £594,000. The principal manufacture is sugar, which is annually exported to the value of £300,000. The administrative headquarters are at Alipore, a suburb of Calcutta; the military cantonments are at Barrackpore. Other towns are Diamond Harbour, Barasat, Dum-Dum, and Port Canning.

Peri. Jacopo, born in Florence about 1570, is celebrated as the earliest operatic composer. He introduced recitative, and his *Dafne* (1597) and *Euridice* (1600) were the first real operas known to have been performed. He died about 1638, but the exact date is unknown. See Fétis, *Biographie des Musiciens* (new ed. Par. 1878).

Perianth (Gr. 'around the flower') is a botanical term which may include the outer envelopes, consisting of a distinct calyx and corolla, but which is usually restricted to cases where these look so much alike (as in the tulip and hyacinth) that they cannot be readily distinguished, or where one whorl is really absent (as in the nettle).

Pericarditis, or Inflammation of the Fibro-Serous Membrane of the Heart, is a disease of frequent occurrence which generally appears during an attack of Rheumatic Fever (q. v.). P. also occurs as the result of cold, of renal disease, of specific fevers, of wounds by fractured ribs, and of the extension of inflammation from the lungs or pleura. In the early stage there is exudation of lymph or serum; at a later stage, false membranes are formed; and, at a still later stage, the two sides become glued together, forming adherent pericardium. Owing to the continual movement of the heart, the lymph is deposited in layers, just as the tide leaves the sand ribbed, and, in some instances, it is shaggy like the rough surface of tripe. The general symptoms of P. frequently attract little attention; but the most obvious are pain in the cardiac region, increased by cough, pressure, or lying on the left side. The action of the heart is irregular and intermittent, especially after fatigue or excitement, and there is usually headache, difficulty of breathing, disturbed and restless sleep, passing into delirium in fatal cases. The local symptoms are, at the earliest stage, on auscultating, a to-and-fro friction sound from the serous membranes not gliding smoothly upon each other, and there is usually a systolic bellows murmur which may mask the friction sound. When effusion has occurred, the dilated pericardial sac assumes a pyramidal form, and its region is marked by dulness. When the pericardium becomes adherent, the dulness is that of the normal heart. P. is a very grave malady, and when it results in endocarditis it may leave permanent valvular disease. When the effusion is copious and rapid, and when it supervenes in the course of a chronic disease, it is generally fatal. The prognosis in P. is determined rather by the complications than by the disease itself. In cases of a mild type the disease generally begins to yield within a week or ten days, and a cure may be effected

in about three weeks. Pericardial adhesions may, however, remain and occasion other structural changes of the heart. In all cases of rheumatic fever, the condition of the heart should be constantly and carefully observed, and the treatment should have direct reference to cardiac complications. In cases of such a grave nature, the treatment should be left exclusively in the hands of a skilful physician. General blood-letting, formerly so prevalent, has now been abandoned; but the local application of leeches may do good in the early stages of the disease, and should be followed by the application of hot poultices and fomentations. When effusion has occurred, blisters are serviceable. Mercury, combined with squills and digitalis, is useful as a diuretic and absorbent. Iodide of potassium is also largely used. The strength should be supported by strong soup and beef-tea. Perfect rest of body and mind is of primary importance. Cooling drinks may be taken freely throughout the course of the disease.

Pericardium ('round the heart'), the name given to the conical sac or bag which contains the heart and the beginnings of the great vessels entering or leaving that organ. It is situated behind the breast-bone and the cartilages of the ribs of the left side, from the third to the seventh inclusive. The apex of the sac is directed upwards, while its base is attached to the central tendon of the *midriff* or *Diaphragm* (q. v.). The remains of the *thymus gland* intervene between the P. and sternum in front, while behind the sac is in contact with the *æsofagus* or gullet, the bronchi, and the *descending aorta*. It is covered at the sides by the pleura or lining membrane of the chest. The P. belongs to the class of structures known as *fibro-serous membranes*. The *fibrous* or outer layer is of firm texture, the more delicate *serous* layer covering the heart, and then being reflected on to the inner surface of the P. The P. in this view is therefore a double sac, consisting of a portion (*visceral*) investing the heart, and of a *parietal* portion. The serous layer secretes a small quantity of *serous fluid*, which serves to render easier the movements of the heart within its sac.

Pericarp. See FRUIT.

Pericles (Gr. *Perikles*), the most distinguished of Athenian statesmen, was the son of Xanthippus, victor at Mycale, 470 B.C., and of Agariste, great-grand-daughter of Cleisthenes, tyrant of Sicyon. The date of his birth is unknown. His early life was spent in study, and his education was most thorough. Music, an essential element in Greek culture, he acquired under Pythocleides, politics under Damon, philosophy under Zeno of Elea and Anaxagoras. The instruction of the last named had on his plastic mind an enduring influence, and contributed much to the formation of his character. P. derived from his intercourse with this great thinker and teacher not only the mould of his mind, but that purity of style, grandeur of diction, loftiness of sentiment, and dignity of soul which characterised him throughout his long and brilliant career. His oratory was singularly forcible. In the sweetness of his voice and in the flow and distinctness of his utterance he resembled Peisistratos (q. v.). His easy dignity was only equalled by his unrivalled self-command. His figure was graceful, his bearing calm and resolute.

When P. entered off his public career, 469 B.C., Aristides was dead, Themistocles in exile, Cimon abroad. The leadership of the democracy was his vocation; and the sincerity of his political convictions is indisputable. Selfishness, love of place, and political success had no place in his disinterested life. He was a 'Liberal,' a 'Radical,' from principle alone. Whether in Assembly or Senate, to the duties of his office he devoted himself with great assiduity and discretion. His friends and partisans were selected with great care. Ephialtes was the ablest of them. In 461 B.C., through the agency of Ephialtes, he struck a severe blow at the Areopagite or aristocratic faction, depriving them in great part of their political sway. This was the first triumph of the democrats. A second victory was the ostracism of Cimon. In 457 B.C. was fought the unfortunate battle of Tanagra, in which P. performed prodigies of daring and valour. His general policy, however, was directed against foreign conquest or territorial increase, then so popular. In 454 B.C., after the failure of the Thessalian expedition, P. invaded Sicyon and routed its forces. Immediately after he proposed and carried Cimon's recall. With characteristic magnanimity P. now proposed a grand Hellenic confederation, the aim and object of which was to end for ever

the mutual destruction of kindred nations, to make the Hellenic race one mighty people, and Hellas one firmly cemented nation fit to defy the world. The idea was in all respects a noble one. Had it been carried out, Rome might never have been empress of the world. A noble people of a noble stock might still have controlled the Bosphorus, and the Muslim Caliphate might never have acquired ascendancy. But Sparta was self-willed and blind. Athens, the 'eye of Greece,' and Lacedæmon, her powerful rival in arms, were irreconcilable. The Peloponnesian War was inevitable. In 448 B.C. the Delphians were deprived by the Phocians of the oversight of the temple of Apollo. A Spartan force restored the temple to the Delphians in consideration of precedence in consulting the oracle being granted to Lacedæmon. Three years later a rebellion broke out in Northern Hellas. Athens was threatened. P. declined to fight with the insurgent states at once. Sparta accepted a bribe and retired. Cimon was now dead. Thucydides was the head of the aristocratic party. In 444 B.C. he tried to overthrow P. but without success. Thucydides was ostracised. The organised opposition of the aristocratic party was broken up. Still P. was by no means free from annoyance. Soon after the war between Samos and Miletus broke out. The Milesians were vanquished, and in their distress applied for relief to Athens. P. supported the Milesians, established a democratical constitution in Samos, and imposed on them a contribution of 80 talents. Immediately on P.'s return the Samians again revolted, were again defeated, and in 440 B.C. a peace was concluded. The position of Athens became from day to day more critical. From 490 B.C. she had been the head of the allied states, and guardian of the common treasury kept in Delos. P. removed the treasury to Athens. The charge made against him of appropriating the sums thus transferred to state purposes is true, but it is also trivial. The Athenian fleet and the army were meant to be—in accordance with the policy of P.—a national force. Undoubtedly P. spent the money of the allies freely on Athenian sculpture and architecture, but it is not mere rhetoric to affirm that all the nations of Europe, and all later ages, have in consequence become participants of the bounty of P. The Parthenon, the Odeum, and the Propylæa, with many other splendid edifices, are 'the work of his power.' Industry and commerce prospered greatly under his rule, and literature and the drama flourished by his kindly influence. He died in 429. Two years before his death the Peloponnesian War broke out (431 B.C.), fatal, indeed, to Athens, but in no way resulting from the prudent and popular government of P. For an account of the relation between P. and Aspasia, see ASPASIA. See also William Watkiss Lloyd's *Age of P.* (2 vols. Lond. 1875), and a monograph by Daniele Pollaveri (Rome, 1876).

Peridot. A name given by Ilauy to a variety of Chrysolite (q. v.), and derived from the Arabic *feridat*, 'a precious stone.'

Périer, Casimir, was born at Grenoble, 21st October 1777, received his education at Lyon, served in the Italian campaign of Bonaparte, and after his return to Paris entered a large banking concern founded by his father and his brother Scipio. Under the Empire the bank prospered greatly, and at the Restoration P. attracted a great deal of attention by the publication of three pamphlets upon the loans contracted for the liberation of the territory. In 1817 he was returned to the Assembly, where, though he combated the absolutism of the Bourbons, his support was always rendered to the constitutional monarchy. In 1824 the Chambers were packed by the 'quatrecent's' of an absolutist Ministry, but P. retained his attitude of moderate Orleanist. He was elected for the departments both of the Seine and the Aube in 1827, a mark of the high estimation in which his services were held outside the Assembly. In 1830 he was re-elected, and during the Revolution of July he exerted himself to the uttermost to preserve peace among the Parisians, and to make their triumphs bloodless. Called to the presidency of the Chambers, he had to decline it on the score of ill-health, but he entered the Cabinet of 10th August. On the 13th March 1831, though filled with presentiments of evil for his country, he assumed the presidency of the council, applying himself with great earnestness to measures by which he meant to tranquillise the domestic feuds whilst peacefully adjusting foreign relationships. In the new Assembly he endeavoured to found a majority, but its first vote was antagonistic. Had it not been that the question of Belgian independence immediately rose for settlement he would

have resigned at once. Under him the public credit was re-established, and government seemed even to be secured on a firm basis, when, exhausted by his labours, P. succumbed to an attack of cholera, 16th May 1832. Guizot, who was in various respects his political disciple, gives a vivid and impressive picture of P. in his *Mémoires*.—**Auguste Casimir Victor Laurent P.**, son of the preceding, was born in Paris, 20th August 1811, entered the diplomatic service at an early age, and was secretary of embassy at various European courts. In 1846 he was elected a deputy for the First Arrondissement of Paris, and after the Revolution of 1848 supported generally the policy of Louis Napoleon, without, however, becoming a Bonapartist. He protested against the *coup d'état* (2d December 1851), was imprisoned for some days, and on his release withdrew into private life. He reappeared after the fall of the Empire, was twice appointed Minister of the Interior by M. Thiers (in October 1871 and May 1873), and on June 15, 1874, carried a motion in the National Assembly in favour of a formal recognition of the Republic. An Orleanist of the Orleanists, he saw that the safety and happiness of France did not lie in the direction of the famous Fusion, and by example and teaching he was able to transmute his friends into Republicans. To him, next after Thiers and Gambetta, the Republic owes its existence. In December 1875 P. was elected to the Senate. He died at Paris, 6th July 1876.

Perigee. See APOGEE.

Périgueux, chief town of the department of Dordogne, France, on the right bank of the Isle, a tributary of the Dordogne, 66 miles W.N.W. of Bordeaux by rail. The streets are narrow and irregular, and a part of the city is surrounded by old walls. The chief building is a splendid cathedral of the 11th c., after the style of St. Mark's at Venice. Statues of Fénelon, Montaigne, and Marshal Bugeaud adorn the chief streets. P. is a bishop's see, has a lyceum, a museum rich in antiquities, and a library of 20,000 vols. The chief articles of commerce are truffles, truffle-pies (*Pâtés de P.*), turkeys, wine and corn, liqueurs, paper and wool stuffs. Pop. (1872) 21,316. P. occupies the site of the ancient *Isurana*, capital of the Petrocorii, from whom the modern town takes its name. In the *acit*, the oldest part of the town, are remains of a Roman amphitheatre, fountains, an aqueduct, and a round building 88 feet high and 216 feet in circumference, supposed to have been part of a temple of Venus.

Perihelion. See APHELION.

Perihepatitis, or Inflammation of the Capsule of the Liver and Glisson's Capsule, is generally caused by disease of the liver itself, or by inflammation of neighbouring structures, such as peritonitis and pleurisy. The prominent symptoms are tenderness on pressure, motion, or deep inspiration; but the disease is not serious unless the inflammation extends to the portal or hepatic veins, or causes obstruction of the larger bile-ducts.

Perim', a small island at the entrance of the Red Sea, 1½ miles from the Arabian and 9 from the African coast. It is about 3½ miles long, with an average width of 1½ miles. The surface is a broken tableland, and the fort and lighthouse stand on a cliff 200 feet above the sea. Water for drinking is supplied by condensation, and even that for bathing purposes requires to be brought from the mainland. There are no trees for fuel, and there is no agriculture; but large flocks of goats belonging to the Somali inhabitants browse upon grass and the leaves of shrubs. A curiosity found on the coast is the shell of *Indacna gigans*, which sometimes attains a diameter of 5 feet, and a weight of 500 lbs. The climate is healthy. P. was known to the Greek geographer Ptolemy by the name of Perantonosiam. In the 17th c. it was much infested by pirates. It was first occupied by a British force in 1799, at the time of the war with the French in Egypt, but again abandoned in the same year. In January 1857 it was permanently occupied by the British. An English officer and a detachment of sepoys from the garrison (50 men) at Aden are relieved every two months. A proposal is under consideration to erect a casemated fort with iron shields at a cost of £82,000. There is a good harbour on the S. coast, and the fort commands the Strait of Babel-Mandel on both sides. The passage generally taken by vessels going to and from the Red Sea is the narrow one on the E. side of P.

See a report by Lieutenant King in *Selections from the Records of the Bombay Government*, No. 49 (1827).—There is another P. in the Gulf of Cambay, forming part of the Bombay district of Ahmedabad. It is chiefly celebrated for its ancient Buddhist sculptures and the enormous quantities of fossil bones of mastodons, &c., which have been dug out of the conglomerate.

Perimeter. See CIRCUMFERENCE.

Period is the time during which a physical phenomenon goes through all its changes. Thus in astronomy the P. of rotation of any celestial body is its time of rotation round its axis, and the period of revolution of a satellite comet or planet is the time it takes to complete one revolution round its primary. A simple oscillating pendulum gives the clearest idea of what is meant by a true periodicity. Its P. is the time which elapses from its passing through any one position, to its passing through the same position in the same direction again. Pendulum motion is very approximately a simple Harmonic Motion (q. v.), which is theoretically the simplest periodic motion possible in nature. According to Fourier's theorem, the most complex periodic motion can always be expressed in terms of a series of simple harmonic motions, whose periods are $0, 1, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \frac{1}{5}, \frac{1}{6}, \frac{1}{7}, \frac{1}{8}, \frac{1}{9}, \frac{1}{10}, \frac{1}{11}, \frac{1}{12}, \frac{1}{13}, \frac{1}{14}, \frac{1}{15}, \frac{1}{16}, \frac{1}{17}, \frac{1}{18}, \frac{1}{19}, \frac{1}{20}, \frac{1}{21}, \frac{1}{22}, \frac{1}{23}, \frac{1}{24}, \frac{1}{25}, \frac{1}{26}, \frac{1}{27}, \frac{1}{28}, \frac{1}{29}, \frac{1}{30}, \frac{1}{31}, \frac{1}{32}, \frac{1}{33}, \frac{1}{34}, \frac{1}{35}, \frac{1}{36}, \frac{1}{37}, \frac{1}{38}, \frac{1}{39}, \frac{1}{40}, \frac{1}{41}, \frac{1}{42}, \frac{1}{43}, \frac{1}{44}, \frac{1}{45}, \frac{1}{46}, \frac{1}{47}, \frac{1}{48}, \frac{1}{49}, \frac{1}{50}, \frac{1}{51}, \frac{1}{52}, \frac{1}{53}, \frac{1}{54}, \frac{1}{55}, \frac{1}{56}, \frac{1}{57}, \frac{1}{58}, \frac{1}{59}, \frac{1}{60}, \frac{1}{61}, \frac{1}{62}, \frac{1}{63}, \frac{1}{64}, \frac{1}{65}, \frac{1}{66}, \frac{1}{67}, \frac{1}{68}, \frac{1}{69}, \frac{1}{70}, \frac{1}{71}, \frac{1}{72}, \frac{1}{73}, \frac{1}{74}, \frac{1}{75}, \frac{1}{76}, \frac{1}{77}, \frac{1}{78}, \frac{1}{79}, \frac{1}{80}, \frac{1}{81}, \frac{1}{82}, \frac{1}{83}, \frac{1}{84}, \frac{1}{85}, \frac{1}{86}, \frac{1}{87}, \frac{1}{88}, \frac{1}{89}, \frac{1}{90}, \frac{1}{91}, \frac{1}{92}, \frac{1}{93}, \frac{1}{94}, \frac{1}{95}, \frac{1}{96}, \frac{1}{97}, \frac{1}{98}, \frac{1}{99}, \frac{1}{100}$, times the period of the complex motion. In all departments of physics, periodic phenomena are constantly recurring, and to analyse these into their simple harmonic components is the great aim of physical and mathematical research. A musical note owes its peculiar character to its periodicity, notes of the same fundamental P. having the same pitch. The different quality of notes of the same pitch is due to the presence of different secondary harmonic functions, whose periods are in simple numerical relation to the common fundamental harmonic. In other words, the harmonic components expressed by Fourier's theorem differ for the two notes. (See SOUND.) In physical optics, the striking phenomena of diffraction, interference, and polarisation are all explained as caused by the superposition of simple harmonic motions. The simpler astronomical periods have already been noticed. No planet or satellite, however, returns accurately to the point from which it started, or describes the same orbit twice successively. The perturbations due to the other members of the system give rise to irregularities, which, however, are themselves subject to a periodic law. For example, because the orbits of the planets are situated in different planes, the apsidal line of each (see APOSE) is constantly rotating at a definite mean rate. In the case of the earth this is what is known as the precession of the Equinoxes, and its P. is 25,868. The regression of the moon is a precisely similar phenomenon. Its P. is 6940 days, or about nineteen years, and is the well-known Metonic Cycle (q. v.), during two successive ones of which lunar and solar eclipses occur in very nearly the same order. Like all astronomical cycles, it has not, however, a perfect periodicity. See CHRONOLOGY, CYCLE, EPOCH, &c.

Periodicals (in literature) are reviews, magazines, and similar publications distinct from newspapers, appearing at regular intervals. The review is devoted to literature, science, criticism, politics, theology, &c. The contents of the magazine are still more miscellaneous, and include novels, tales, sketches, verses, &c. Among the earliest reviews in this country were the *Weekly Memorials for the Ingenious* (1681-82), which contained, in addition to original matter, translations from the older French *Journal de Savants*, the *Memoirs of Literature* (1725), and the *Literary Journal* (Dublin, 1744-49). The *Monthly Review* established by Griffiths (1749-1844), and the *Critical Review* (1756-1817) founded by A. Hamilton with Smollett's co-operation, were the leading reviews of the latter half of the 18th c. The *Edinburgh Review* was started in 1802 and the *Quarterly Review* in 1809, with the support of the Whig and Tory giants of the day respectively. The *Westminster Review* appeared in 1824 to champion the advanced liberal and utilitarian views of Bentham and Bowring. The *Dublin Review* (Roman Catholic) dates from 1836 (new series 1863), and the *North British Review* from 1844. In these and many other quarterly reviews the system has been uniform. Each number consists of several lengthy papers purporting to be reviews of published works, but being usually original and elaborate essays on the subjects treated. Of late years the French method of appending the names of contributors, and of making the contents more varied in character and even antagonistic in opinion, has been adopted in such publications as the *Fortnightly Review* (1865), *The Contemporary*

Review (1865), and the *Nineteenth Century* (1877). The great reviews have commanded the services of famous statesmen, philosophers, historians, and theologians; and their columns, rich in brilliant writing and learned research, contain valuable additions to modern literature. For some notices of weekly reviews, such as the *Saturday Review*, the *Spectator*, the *Athenaeum*, *Academy*, &c., see NEWSPAPER.

The favourite form of magazine in the first half of the 17th c. in England was that represented by the famous *Tatler* (1709-10) and *Spectator* (1711-14). Among the many similar publications which succeeded were Johnson's *Rambler* and Mackenzie's *Mirror* and *Loinger*. The *Gentleman's Magazine*, which still lives, was started in 1731, and for a long time was the leading periodical. It contained sketches and essays, and for some time an account of parliamentary proceedings and of historical matter, including obituaries. The *London Magazine* (1732-84) and the *Scots Magazine* (the first magazine north of the Tweed, 1789-1817) were popular serials. *Blackwood's Magazine* (1817) (see BLACKWOOD) and *Fraser's Magazine* (1830) were of a higher order than any of their predecessors. The usual price of the leading magazines was 2s. 6d. till the appearance of *Macmillan's Magazine* (see MACMILLAN) in 1859 at 1s., after which the admirable *Cornhill*, originally edited by Thackeray, *Temple Bar*, the gossiping *London Society*, and *St. James's Magazine* (all in 1860), *Belgravia* (1866), and others entered into the field at the same price. Among the still cheaper publications of excellence are *Chambers's Journal* (1832), *All the Year Round* (long associated with Dickens, 1859), *The Leisure Hour* (1852), *The Argosy* (1856), and *Good Words* (1860). In 1877, according to May's *British and Irish Press Guide*, there were 779 P. other than newspapers circulating in the United Kingdom at prices varying from 4d. to 10s. 6d. per number (260 at 1d., 75 at 2d., 40 at 3d., 98 at 6d., 63 at 1s., 14 at 2s., 19 at 2s. 6d., 10 at 6s., and the remainder at various prices); 579 were published in the metropolis, 115 in the rest of England, 18 in Wales, 41 in Scotland, 25 in Ireland, and 1 in the British Isles. Undernoted is a classification of the numbers published at different intervals:—

	Half-yearly, irregular, and various.	Every two months.	Quarterly.	Monthly.	Fortnightly, and twice a month.	Weekly, and oftener.
Metropolis	32	3	78	401	1	64
England (Provincial)	7	—	4	82	3	16

Among the best of the 352 having a religious tendency are the *Sunday Magazine*, *Day of Rest*, and the *Sunday at Home*; 89 were P. for the young, chief among them being *Every Boy's Magazine*, *Aunt Judy's Magazine*, and the infantile *Peepshow* and *Chatterbox*; 95 were trade publications; 58 were identified with the temperance movement, and 14 with the interests of labour. The *Art Journal* (1849) and *Portfolio* (1870) are pre-eminent among magazines devoted to art. The number of illustrated publications increases every year, particularly those embellished by photographic, chomo-lithographic, and other new processes. There were 272 illustrated P. in 1877, 17 with coloured plates, and 9 by photography.

In France the *Journal des Savants* was started by Denis de Sallo in 1665. The year 1672 saw the birth of the *Mercurie Galant*, subsequently called the *Mercurie de France*, which gave reviews of poetry and the drama. The *Mémoires de Trévoux* (1701-67) was an able Jesuitical organ, its modern successor being the *Études de Théologie*, &c. The *Magasin Encyclopédique*, which ultimately altered its name to the *Revue Encyclopédique*, was founded in 1775. Guizot was for some time associated with the *Revue Française* (1828-30, 1837-38, 1855-60, and 1861-66). The *Revue de Paris* (1829-58) had a deserved reputation for fiction. By far the most celebrated of modern French reviews is the *Revue des Deux Mondes* (founded 1829), which combines the features of the English magazine and review, and has under the direction of M. Buloz secured the

services of many of the best modern writers of France, Sainte-Beuve, Thiers, De Musset, About, George Sand, Renan, and others. The *Revue de France* and *Revue Britannique* are perhaps next in importance. The number of reviews published in Paris is very great, but the vast majority are on special and circumscribed subjects. The *Gazette des Beaux Arts* (founded 1859) and *L'Art* are publications of world-wide fame. The *feuilleton* in French newspapers supplies to some extent the want of magazines similar to those published in England.

In Germany reviews have for many years been numerous. The *Acta Eruditorum* appeared in Latin at Leipsic in 1682, and lasted for half a century. The *Gelehrte Anzeiger*, founded in 1739, is still published. In the latter half of the 18th c. most of the leading towns, Frankfurt, Halle, Kiel, Gotha, &c., had their own *Gelehrte Zeitung*. Lessing contributed to the *Briefe die Neueste Literatur betreffend* (1759-65). Jena was famous for the *Allgemeine Literaturzeitung* (1785, transferred to Halle in 1804), and the *Jenaische Allgemeine Literaturzeitung* (1804-1848). Among modern and leading critical authorities are the *Deutsche Vierteljahrsschrift* (modelled on the English *Quarterlies*), *Historische Zeitschrift* (eight times a year), *Unsere Zeit*, and the *Heidelberger Jahrbücher*. The *Deutsche Rundschau*, a monthly magazine and review founded at Berlin in 1875, has been very successful. The *Gartenlaube*, both for the excellence of its literature and the beauty of its illustrations, takes a high place among German magazines. *Der Salon und Dalmien* may also be mentioned. The *Gegenwart* is one of the best critical weeklies. Some important reviews are published in Austria, such as the *Allgemeine Literaturzeitung* (Catholic), the *Internationale Revue*, and the *Oesterreichische Revue*.

One of the earliest critical journals of Italy was the *Giornale dei Letterati*, first issued at Rome by Nazzari about 1668. The *Nouvelle Litteraire*, founded in 1740, was an erudite publication. The scholarly *Rivista Contemporanea* (Turin) is the Italian *Revue des Deux Mondes*, and has engaged the pens of some of the best modern Italian essayists. The *Rivista Europea* and the *Nuova Antologia* of Florence are also of high importance. Since the formation of the kingdom of Italy a great impulse has been given to serial publications at Rome, where over 30 P. are at present published.

A number of bulky reviews of considerable merit appear in the Russian press, such as the *Vjstnik Evropa* (founded in 1802) and the *Ruski Vjstnik* (1808). The *Nordisk Universitets Tidsskrift* (1854) is a well-managed quarterly review published by four Scandinavian universities.

In the United States the *General Magazine*, started at Philadelphia by Franklin in 1711 on the plan of the *Gentleman's Magazine*, was a venture which perished in six months, and all attempts at similar serials were comparative failures until after the Revolution. The *North American Review* (Boston, 1815) has proved the most permanent of American critical publications. Among others are the *National Quarterly Review* and the *International Review* (published six times a year). The *Knickerbocker* and *Putnam's Monthly* were two of the best of the light American magazines of the past. The *Atlantic Monthly*, founded in 1857, was for some time edited by Lowell, and occupies a prominent place. Harper's *New Monthly Magazine* has a very wide circulation, and *Scribner's Magazine* (New York), the *Galaxy* of Philadelphia, the *Overland Monthly* of San Francisco, and the *Lakeside* of Chicago, enjoy high favour. An immense number of American serials are also in the interests of the various religious sects, a condition of things incompatible with the highest literary excellence.

Periœci (Gr. 'dwelling round about') in Laconia formed an intermediate class between the freemen and the slaves. Descended from the conquered Achæans, they were personally free, but had no political rights, being subject to laws which they had no voice in making, and obeying magistrates whom they had no voice in choosing. They formed a large proportion of the population, numbering 10,000 at the battle of Platœa (479 B.C.), and they had cities of their own, some of which, as Amyclæ, seemed to have enjoyed privileges beyond the rest. The trade and industries of the country rested almost exclusively in the hands of the P., and they also cultivated the arts, which the Spartans themselves despised. The term P. was also applied by geographers to people living in the same parallel but opposite meridians.

Periosteum (Gr. 'around the bone'), the fibrous membrane covering the surface of bones, and serving to support the blood-vessels concerned in their nutrition. The P. is firmly adherent to the surface of the bones at every point, except at their extremities, where they are invested with cartilage. This membrane is thickest and most vascular in its young condition, and grows thin in old age. It consists of two layers of membrane, closely applied. The P. is concerned largely with the growth of bone, and by the experiments of Syme (see **OSSIFICATION**) was found to be concerned in the repair of bones after injuries.

Periostitis, or **Inflammation of the Periosteum**, is almost always associated with more or less inflammation of the substance of the bone itself, and is, strictly speaking, one of the forms of Ostitis (q. v.). P. occurs in two distinct forms, viz., the common or chronic, and the acute or diffuse. Chronic P. is often a consequence of syphilis, and, when limited to a small extent of surface, is called a *nodule*, its most common seat being the superficial bones, as the cranium, tibia, clavicle, &c. (See **NODES**.) The ordinary cases of chronic P. are really cases of inflammation of the whole bone, with deposits on its surface, induration and thickening. *Diffuse or suppurative P.*, leading to acute periosteal abscess, may occur as a result of local injury or as a serious disease of the bone, producing a general pyæmic condition, or it may be itself a manifestation of general pyæmia. In such cases, the treatment must be energetic and decided. When the pain and tension is severe, a free incision should be made down to the bone, though the presence of fluid be not established. In less severe cases, local depletion and iodide of potassium will lead to a cure without suppuration.

Peripateticism (Gr. *peri*, 'about,' and *patô*, 'I walk'), the philosophical system of Aristotle (q. v.), so named because he lectured in a *peripatos*, or covered walk of the Lyceum at Athens.

Peripteral (Gr. *peri*, 'around,' and *pteron*, 'a wing'), a term used in Grecian architecture to denote a temple, the *cella* of which was surrounded by a single row of columns, as distinguished from the *dipteral*, in which two rows of columns were employed.

Peris (Pers., from Zend. *pairikā*, not akin to Eng. *fairy*), in Oriental folklore, are male and female spirits, the offspring of the fallen *Jinns*, but themselves beautiful, happy, and beneficent, ever at war with the wicked *Devils*. Their exclusion from Paradise forms the theme of Moore's *Paradise and the Peri* in *Lalla Rookh*.

Perissodaactyla ('uneven toed'), one of the chief divisions of the order of *Ungulate* or 'hoofed' quadrupeds. The toes are uneven in number, the tapirs exhibiting the only exception to the rule. The dorso-lumbar vertebrae number not less than twenty-two, and a third trochanter is developed on the thigh-bone. When horns are developed (as in rhinoceroses), they do not exist in pairs, and these organs are not supported by 'horn cores.' The stomach is of simple conformation, and the *cæcum* is large and capacious. The families of the *Equidae* (horses), *Rhinocerotidae*, and *Tapiridae* represent this group, along with the extinct family *Palæotheriidae*.

Peristaltic Action, the term given to the movements of the intestines, by means of which the food is propelled along the intestinal tube. The name of *vermicular motion* is also given to such movements. The source is the muscular coat which the intestine, in common with other parts of the alimentary canal, possesses. The contraction of the intestines may be seen to pass along the gut in an undulating or wave-like manner. The longitudinal fibres of the intestinal muscular coat are the first to contract, and by their action draw a portion of the intestines backwards, as it were, over the food to be propelled, this action serving in all probability to consolidate the food, and to thus render its propulsion more readily effected. The circular fibres next come into play, and as they contract from behind forwards they propel the food onwards to the next segment of the intestine. The movements of the intestines are not perceptible in health, but under abnormal stimulation, as after the administration of purgative medicines, the sharp contraction of the tube may be felt. The muscular fibres of the large intestine are stronger than those of the small intestine, owing to the greater

power required for the propulsion of the fecal matters with which the large intestine has to do.

Peristyle (Gr. *peri*, 'around,' and *stylos*, 'a column'), in architecture, a court, square, or cloister surrounded with columns, or having columns on three sides. The term is also applied to the colonnade itself.

Peritoneum (Gr. 'what is stretched round'), the lining membrane of the abdominal cavity, analogous to the *Pleura* (q. v.) of the chest. It is one of the *serous membranes* of the body. The P. is in reality a closed sac, one layer or side of which is applied to the abdominal walls, and the other reflected over the various organs contained within the abdominal cavity. Like the *Pericardium* (q. v.), it thus consists of a *visceral* and of a *parietal* layer. The layers enclose a central (*peritoneal*) cavity, which in the male is completely shut, but in the female communicates with the outer medium through the *Fallopian tubes* or *oviducts*. The surfaces of the P. which line its cavity are smooth and glistening, and secrete a little serous fluid, which, when increased to an abnormal extent, causes *dropsy*. The two layers of the P. are thus adapted to move easily upon each other, and to facilitate the movements of the viscera in digestion. The general arrangement of the P. may be studied if we commence with the upper wall or roof of the abdomen, where the membrane is reflected from the *midriff* or *diaphragm* on to the surface of the liver, where it aids in forming the ligaments (*suspensory*, *lateral*, and *coronary*) of that gland. From the diaphragm the P. is also reflected on to the *spleen*, and to the stomach, at the point where the gullet enters the organ, and where it forms the *gastro-suspensory ligament*. The liver is covered by the P., which passes thence to the stomach, where it forms a double fold (the *small omentum*). After leaving the stomach, the P. hangs down over the small intestine, and is then known as the *great omentum*, which on the left side joins the small omentum, and on the right invests the *colon*, or middle portion of the large intestine. The membrane also forms the *mesentery*, or layer which supports the intestine and attaches it to the walls of the body, and over which the *lacteal* or *absorbent vessels* pass on their way to the *thoracic duct*. The P. covers the upper part of the *rectum*, and in the male forms a fold between the *bladder* and the terminal part of the intestine named the *recto-vesical fold*. In the female it covers a small part of the posterior wall of the *vagina*, and is then reflected over the posterior surface of the *uterus*, whence it passes in the form of the *broad ligaments* to the hinder surface of the bladder, which in both sexes is therefore uncovered in front by P. The cavity of the P. already spoken of consists of two compartments which communicate with each other. The larger cavity extends from the midriff to the pelvis, whilst the smaller cavity lies behind the small omentum and stomach. The cavities communicate by an aperture, the *Foramen of Winslow*, placed behind the free border of the lesser omentum, and having the *inferior vena cava* behind, the *Spigelian lobe* of the liver above, and the duodenum below.

Peritonitis, or Inflammation of the Peritoneum.

The peritoneum, or serous membrane lining the abdominal and pelvic cavities, and investing the viscera, is liable to acute and chronic inflammation, similar to that which occurs in all serous membranes, characterised by capillary congestion, redness, interstitial growth or exudation, so that the membrane loses its transparency, and is thickened, and sometimes ribbed or villous according to position. The surface of the intestines is injected, and they may be slightly glued together with soft yellow-grey lymph, shifting from one fold of the peritoneum to another. The effused lymph, characteristic of chronic cases, gravitates to the pelvic and lumbar regions, where it may escape observation for a time, or it may increase and distend the abdominal walls. P. tends to spread until the whole membrane is involved, and when arrested there may follow absorption of the fluid, organisation of the false membrane, thickening of the peritoneal surface, and adhesion of adjacent organs. The fluid, if purulent, may form an external abscess, or escape into the intestines. P. may be occasioned by external injuries, perforations of the intestines, strangulated hernia, extension of disease from neighbouring parts, and exposure to wet or cold; or it may be the result of various blood diseases, as tubercle, Bright's disease, Puerperal Fever (q. v.), &c. In the *acute* form, whatever the cause may be, there are the usual febrile symptoms, with pain in the abdo-

men, increased on pressure or by the slightest movement. The pain is generally very severe, and the patient lies in bed with the legs drawn up, the features are pinched, the expression is anxious, the abdomen is tympanitic, tense, and hot, and vomiting, which is generally present, aggravates the pain; the pulse is rapid, hard, and wiry, the tongue parched, the respiration quick, and the urine is scanty and high coloured. The treatment of *acute P.* consists in absolute rest, maintaining the position instinctively assumed, and guarding the patient against the weight of the bed-clothes by means of a support. When P. is idiopathic, leeches should be applied to the abdomen, and the bleeding should be encouraged by hot fomentations. Opiates should be given, but if there be irritability of the stomach and vomiting, they may be given as enemata, or morphia may be injected subcutaneously to allay the pain. The strength should be supported by beef-tea, eggs, and milk; and in very acute cases an ice-bag over the abdomen, with two or three layers of flannel between, will afford much relief, and subdue the inflammatory symptoms. Small pieces of ice to suck is agreeable, and mitigates vomiting. Counter-irritation, in the acute stage is not admissible, the inflammation being too general for such treatment. *Chronic P.* is generally associated with the strumous diathesis, but it sometimes follows the acute affection. In the former case numerous miliary granules lie within or immediately beneath the membrane, especially in the folds of the peritoneum which compose the omentum. The symptoms of *chronic P.* are obscure and insidious. There is generally loss of appetite, nausea, vomiting, progressive emaciation, and diarrhoea. A pricking pain, which is increased on pressure, is felt in the abdomen, which gradually gets full and tense, and fluctuation may be detected. A friction sound, produced by respiration, or movement of the abdominal walls, may be detected by the ear or the stethoscope. The treatment of *chronic P.* consists in mild, nutritious diet, milk, beef-tea, &c. Syrup of the iodide of iron and cod-liver oil should be administered, and iodine ointment may be applied externally. In severe cases, opium fomentations or counter-irritants may be applied. Very little can be done in the way of curative treatment unless chronic P. be the result of an acute attack. When complicated with disease of the mesenteric glands, phthisis, &c., the treatment must be the same as for these diseases.

Perityphilitis is the term used in medicine to denote inflammation of the areolar connective tissue round the *caecum*, a lesion of frequent occurrence during typhoid fever. It may be caused by accumulations of feces or of foreign substances in the vermiform appendix. When perforation takes place where the bowel is free from peritoneal covering, an abscess generally appears in the iliac region occupied by the cecum; but when perforation takes place directly into the peritoneal cavity, the result will be fatal peritonitis. In the early stage, leeches, followed by hot fomentations and poultices, should be applied, and opium should be given internally. Drastic purgatives should be avoided, and only liquid food should be used.

Periwig (formerly spelled *perewyke*, a corruption of Fr. *peruque*, 'a lock of hair'; Sp. *peuca*, from Lat. *pilus*, 'a hair'), contracted into **Wig**, an artificial covering of hair for the head. The use of the P. may be traced back to the Egyptians, who wore wigs to protect their shaven heads from the sun's rays. False hair was worn by both sexes of the Greeks and Romans; at one time during the Empire the head-dresses of Roman ladies were heightened with false curls and plaits, and later wigs of a blonde colour were fashionable. The P. or peruke was introduced into England from France in the middle of the 16th c. At that time a single lock of false hair constituted a P. An actor is described in *Hamlet* as a 'P.-pated fellow.' With the Restoration a long and very thick wig came into vogue, the combing of which in public was a favourite pastime with beaux. Pepys mentions in his *Diary* that ladies also wore wigs in imitation of gentlemen. Several varieties of wigs were in use before the end of the 17th c., and the following century witnessed additions to the number. In Queen Anne's time 'black-riding wigs,' 'bag-wigs,' and 'night-cap wigs' are spoken of, and during the reigns of George I. and II. 'Ramilie-tails' (so called after the battle of Ramilies), 'bob-wigs,' 'tie-wigs,' and 'pig-tails,' were introduced. The bob-wig, which resembled the natural hair in form, was worn by the middle classes, while the upper classes affected a small wig with a large queue or tail. The three-cornered hat then in fashion was more frequently carried under the arm than on the

head, lest it should disarrange the wig. Wigs fell into disuse about 1760, but the pig-tail, formed of the natural hair, continued for some time longer. Formally curled perukes are now only worn professionally by barristers and churchmen, and sometimes by coachmen of the nobility; and wigs imitating the natural hair are occasionally worn to disguise baldness.

Periwinkle (*Littorina*), a genus of *Gastropodous* molluscs, belonging to the section *Holostomata*, in which the shell aperture is entire, and not indented for the passage of a *siphon*. The shell is of spiral form; its lip is sharp; the whorls are few in number. The *P. (L. littorea)* is the type of the family *Littorinidae*. It is found plentifully in the rocks and tangle between tide marks, and is used for food by the lower classes. Another species is the *L. rudis*. The *P.* is sometimes named the 'whelk' or 'wilk' (*Scotice*); but it is to be distinguished from the true whelks, which are larger, and belong to a separate family—that of the *Buccinidae*.

Periwinkle is the common name of the genus *Vinca* of the natural order *Apocynaceæ*. It consists of about ten species, confined to the eastern hemisphere. Of these, the best known are the Greater and the Lesser *P. (V. major* and *V. minor)*, both evergreen trailing undershrubs, with blue, purple, or white salver-shaped flowers. They are frequently planted in shrubberies and other garden adjuncts, on account of the rapidity with which they overspread and obliterate broken or unsightly ground, giving it a covering of deep shining green. Both are naturalised in various parts of Britain, and probably the latter is a native in England. *V. rosea*, from Madagascar, is cultivated as a greenhouse plant.

Perjury and Subornation. *P.* is a wilful false swearing in any judicial proceeding, in a matter material to the issue or point in question, on a lawful Oath (q. v.) administered by some one of competent authority. To constitute the crime the falsehood must not arise from inadvertence. *Subornation of P.* is the offence of procuring another to commit the crime in question. If any one swears that he *thinks* or *believes* something to be true, which he knows to be false, if the matter sworn to be material to the case, *P.* is committed. The punishment of these crimes was at one time death and forfeiture of goods, afterwards banishment or cutting out of the tongue; it is now fine, imprisonment, or penal servitude.

Perkin Warbeck, a native of Tournay, appears first in English history under the protection of Margaret of York (1490), who professed to find in him a strong resemblance to her royal brother. In 1494 he landed at Cork, and was acknowledged Richard Duke of York, the mayor and citizens declaring in his favour. From thence he went to the court of Charles VIII., who was then engaged in war with England; and subsequently, at the instigation of Margaret, Duchess of Burgundy, landed at Kent, and made an unsuccessful raid. He next went to Scotland, was received by James IV., and married a daughter of the Earl of Huntly. James supported him in two raids upon Northumberland, but the Scottish King having come to an understanding with Henry VII., *P. W.* was once more compelled to seek refuge in Ireland. In 1498 he joined the insurgents of Cornwall, taking the title Richard IV., advanced as far as Taunton, was captured, and hanged, 16th November 1499.

Perleberg, a Prussian town, province of Brandenburg, on the Stepnitz, 75 miles N.W. of Berlin by rail. It has manufactures of machinery, ovens, carriages, wadding, mustard, vinegar, &c., as well as large oil-refineries, tanning-mills, breweries, and printing-offices. Pop. (1875) 7605.

Perm, a government of E. Russia, lying on both sides of the Ural Mountains, and bounded N. by Vologda, W. by Viatka, S. by Ufa, and E. by Tobolsk. Area, 128,245 sq. miles. Pop. 2,198,666. The surface rises gradually to the Ural Mountains, the general elevation of which is from 3000 to 4000 feet. *P.* is drained on the European side by the Kama and its feeders, and on the Asiatic by the affluents of the Tobol. Nearly three-fourths is covered with wood, and only one-twelfth is under cultivation. It is the richest mineral district of European Russia, abounding in copper, gold, platinum, malachite, and salt, and having an inexhaustible wealth of iron ore, and a coal formation extending, with a width of 250 miles, from Tscherdin in the N. to Kirzhigansk and Grobowa, and 45 miles S. into Ufa. The

mines give employment to over 100,000 men, and yield annually to the value of £4000,000. *P.*, the capital of the government, on the right bank of the Kama, 715 miles W.N.W. of Moscow, and on the great road from that city to Siberia. It was founded as early as 1729, and known as the Egotinsky Copper Work, but was first built in 1780 under a ukase of Catherine II. The houses are mostly built of wood, but the streets are broad. There is an active transit trade on the river, but the importance of the town is due to the mining in its neighbourhood. Near *P.* is a great copper-smelting work, and at Motovilichinsk, 2 miles up the river, and on its left bank, a cannon foundry employing upwards of 2000 men, and at which were produced, between its commencement in August 1863 and the end of 1865, 270 cast-steel cannon. Pop. (1875) 22,282.

Permian Period, sometimes known as the *Dyas*, comprises the highest Palæozoic formations which overlie the coal measures. In England, three divisions are recognised. The lower strata consists of Red Sandstone and marl, which pass into the coal measures; the middle form the magnesian limestone; and the upper are composed of the New Red Sandstone. Fossils are scarce; and nearly 50 per cent. are identical with carboniferous forms. *Productus* and *Orthis* die out, as also the low forms of coral; and the gradual disappearance of heterocercal tails among the fish remains is well marked. Traces of the *Labyrinthodon* are observable. In the English representative rocks, a great break in time occurs after the magnesian limestone—a gap which is filled in by formations in other parts of Europe. In Germany there are two well-marked divisions—the Kupferschiefer, contemporaneous with the underlying marls of the British system; and the Zechstein, corresponding in part to the magnesian limestone. At the base is a large mass of red sandstones, conglomerates, and breccias, with porphyries and tuffs, which is the *Rothe-todtliegende* of the German miners; and surmounting the Zechstein, a collection of brecciated limestones and marls which pass conformably into the Banterschiefer of the Lower Trias. In Russia, the rocks are easily correlated to the German system. They occupy a wide track in the ancient kingdom of Perm, from which the name Permian, introduced by Murchison, is derived. Nowhere is there a great development of life, but there are evidences of important physical changes, due to volcanic action and glaciers.

Permit is a license granted to remove spirits liable to excise duties. Any person making paper in imitation of excise paper, or counterfeiting a *P.*, or uttering the same, is guilty of felony.

Permutations and Combinations. When the order or arrangement of a row of objects is changed, they are said to be permuted, and the different arrangements which can be formed are termed permutations. Thus, the three letters *a, b, c* can be arranged in six distinct ways, namely, *abc, acb, bac, bca, cab, cba*. Similarly the number of permutations of four things is 12. Assuming the number of permutations of *n* things to be the product $1 \cdot 2 \cdot 3 \cdot 4 \dots n$, briefly written $n!$ —a rule which evidently holds for 2, 3, and 4—it is required to know how many there are of $n+1$ things. Now, each n -permutation can form with the $(n+1)$ th object $(n+1)$ permutations, according to where the new object is inserted. But there are $n!$ of these n -permutations; hence there are $(n+1) \times n! = (n+1)$ permutations of $n+1$ things. If the rule holds for n things, it holds for $n+1$; but we know it to hold for 4, therefore it must hold for 5, 6, 7, and any number. The number of possible arrangements of n things taken one at a time is obviously n . Each one can form with others $(n-1)$ pairs, in which it stands first; hence it is easily seen that the number of permutations of n things taken two and two is $n(n-1)$. And generally it can be demonstrated that the number of permutations taken r together is $n(n-1)(n-2) \dots (n-r+1)$. If the grouping together of a number of objects is considered without reference to their arrangement, the question becomes one of combinations. Thus though there are $r!$ permutations of r things taken all together, there is only one combination. Hence for every combination of n things taken r together there are $r!$ permutations;—or (number of combinations) $\times r! =$ number of permutations, and therefore the number of combinations of n things taken r together $= \frac{n(n-1) \dots (n-r+1)}{1 \cdot 2 \cdot 3 \cdot 4 \dots r!}$.

The whole theory of combinations is of the greatest importance in higher mathematics, but for the various fundamental theorems reference must be made to some text-book on algebra.

Bern. See HONEY BUZZARD.

Pernambuco, a province of Brazil on the seaboard, between the provinces of Parahyba, Ceará, Piauí, Bahia, and Alagoas. It has an area of 46,257 sq. miles, with a pop. (in 1872) of 241,539, of whom 89,028 were slaves. The climate is moist and hot, and the soil fertile. The coast-line, which is 120 miles long, is low, and the sugar-cane is extensively cultivated in the neighbourhood. The interior is to a large extent mountainous and wooded, and its principal products are cotton, dye-woods, gums, drugs, &c. The S. boundary of the province is formed by the large river São Francisco, near whose banks cattle are reared in great numbers. Gold is believed to exist in the interior ranges.—**P.**, the third city of Brazil, at the mouth of the Biberibe and Capiberibe rivers. It consists of three portions, divided by channels of water, and connected by bridges and embankments, viz. —Recife, next the sea, on a narrow, sandy peninsula, and the most mercantile part of the city; São Antonio, on a small island, and Boa Vista, on the mainland. The ancient town of Olinda, 3 miles N., now also forms a suburb of **P.** The harbour of **P.** is safe, roomy, well-lighted, and fortified. It is formed by a low sandstone reef which is submerged at high tide, but is a perfect natural breakwater; yet the town has its name (**P.** = 'mouth of hell') from the violent surf that breaks on the reef. The town was formerly very unhealthy, its site being low and wet, and the rainfall very great, exceeding 100 inches annually. Extensive drainage and paving operations, however, have much improved its sanitary condition. **P.** has an arsenal, state observatory, and several important educational institutions. Its trade is very considerable, the imports and exports during the financial year ending 30th June 1875 having amounted in value to £2,181,633 and £1,636,344 respectively. In 1875 there entered the port 525 vessels of 356,922 tons, and cleared 506 of 315,779. The chief exports are sugar, cotton, hides, and rum. Pop. (1872) 116,671.

Pernambuco Wood. See BRAZIL WOOD.

Pernov' (Ger. *Pernau*), a strongly fortified seaport of Russia, in the government of Livonia, at the N.E. corner of the Gulf of Riga, and at the mouth of the river **P.**, 103 miles N. by E. of Riga. **P.** is regularly built, and has three churches. It has extensive trade, the exports in 1874 (chiefly flax, linseed, and corn) amounting to £1,320,150, and the imports (principally salt, coal, and herrings) to £59,140. In 1873 there entered and cleared at the port of **P.** 240 vessels of 38,154 tons. Pop. (1870) 9568.

Perouse, Jean François de Galaup, Comte de la, born at Guo, near Albi, department of Tarn, August 22, 1747, became a midshipman in the French navy in 1756. He was taken prisoner in the battle of Belle Isle (1759), in 1762 returned to France, and served in the East Indies from 1773 to 1777. In 1782 the French Government sent him to destroy the English settlements in Hudson's Bay. He took the forts of Prince of Wales and York; but the expedition ended in the peace of 1783. In August 1785 **P.** was sent to explore the Pacific. He doubled Cape Horn, followed the W. Coast of America to California, crossed the Pacific, and traced the Asiatic coast from Manila to Petropaulovsk. The 'Strait of La **P.**', between the island of Saghalien and the Japanese island of Yesso, still bears his name. From Petropaulovsk he sent his journals and charts to Paris. In September 1787 he started southwards, and a letter was received from him dated Botany Bay, 7th February 1788. After this the expedition disappeared. Searches were made by D'Entrecasteaux in 1791, and by Dumont D'Urville in 1828; and it is now supposed that it was wrecked at Vanikoro, in the New Hebrides, in 1788.

Perpendicular, in mathematics, is the term applied to two lines or planes at right angles to one another, and to a line which is at right angles to a plane. The word is very often used as synonymous with *vertical*.

In fortification, it is technically the line drawn inwards from the point of bisection of an exterior side.

Perpendicular is the name given to the last modification of the Gothic (q. v.) style of architecture which flourished in Britain. It was developed from the Decorated (q. v.) towards

the close of the 14th c., and lasted till about the middle of the 16th c. The term **P.**, first used by Rickman (1817), has reference chiefly to the numerous straight vertical lines which present themselves in the subordinate ornament. Since these, however, are almost everywhere crossed at right angles by straight horizontal lines, *rectilinear* would perhaps be a more exact designation than **P.** The mouldings are thinner, and the recesses of the pillars and buttresses shallower, than in the buildings of the preceding period; and it may be said generally that the **P.** style substitutes lightness and elegance for the massive grandeur so characteristic of the earlier Gothic. A distinctive feature of the style is the square arrangement of the mouldings over doorways, and the constant presence of square panelling, with which sometimes both the exterior and interior walls, and even the vaulting, are covered. In the window mullions the flowing curves of the preceding period are replaced by straight lines, which run upwards till they cut the enclosing arch, and which, in windows of any size, are invariably crossed by several transoms. The roofs are often of a high pitch, and have a magnificent effect, sometimes displaying a peculiarly rich species of vaulting known as Fan Tracery (q. v.). The open wooden roofs of this period are remarkable for their great size and elaborate ornament; the most notable example and the finest specimen of purely English work being that of Westminster Hall (1397-99). Stone porches are frequent, and they are generally enriched with panelling and niches for statuary. The **P.** style is also distinguished by the prevalence of handsome church towers. Fine examples are Gloucester and Winchester cathedrals; St. Mary's, Taunton; St. Stephen's, Bristol; Magdalen College, Oxford, &c.

Perpetual Motion, **The**, as understood in physics, is not the simple continuation of motion for ever. Such, indeed, according to Newton's First Law, would be possible and even necessary, if all resistance to the motion of a body could be eliminated. Physically, of course, even this theoretically possible **P. M.** is not realisable, as far as our experience, at all events, has shown. By 'The Perpetual Motion' is meant doing work out of nothing, or doing work without a previous expenditure of energy. The postulate, then, that the **P. M.** is impossible is simply a part statement of the great doctrine of modern science, the conservation of energy. When work is done work must be spent, which does not necessarily imply the other aspect of the conservation principle, that when work is spent work is also done. To construct a machine which should itself gather power as time passed on, has been the darling scheme of many paradoxers. The searchers after the philosopher's stone and the elixir of life deserve credit to which the circle squarers and perpetual motionists have no claim. These wasted their time in striving after the attainment of what all natural laws pointed out as unattainable; and notwithstanding the present development of science, there are still some monomaniacs who hope to realise their one idea of making an engine work without fuel. The various forms of apparatus devised by these show in many cases an undoubted mechanical ingenuity, which, had it been devoted to a better cause, might have added to the list of Watts and Stephenson's. The physical bearings of the subject are sufficiently considered under **ENERGY**.

Perpetuities, Law Regarding. It has been long ago decided by the law courts of England that succession to real estate cannot be regulated for more than twenty-one years beyond the lives of persons in existence. In Scotland the contrary rule of law prevails. The Act 39 and 40 Geo. III. c. 98, known as the Thellusson Act, prohibits accumulation of income in England for more than twenty-one years beyond the death of the testator. The Act was so called from its having been passed in consequence of the will of the late Mr. Thellusson, a London banker. This will directed the accumulation of an originally immense fortune for three generations, in favour of an unborn descendant. It gave rise to protracted litigation, which consumed the greater part of the intended accumulation.

Perpignan, a fortress of the first rank, and chief town of the department of Pyrénées-Orientales, France, on the Têt, commanding an important pass of the Pyrenees, 5 miles from the Mediterranean, and 40 S. of Narbonne by rail. It has a richly ornamented Cathedral of St. Jean, begun in 1324, a citadel of which the donjon was formerly a castle of the kings of Ara-

gon, a chapel with a fine Moorish gate, and a hôtel-de-ville, rebuilt in 1692. There is some industry in cloth, leather, chocolate, &c., and an important trade in oil, silk, and Roussillon wine. Pop. (1872) 20,211. P. was founded in the 11th c., and belonged to the Kings of Aragon till taken by Louis XIII. in 1642. It was the capital of Roussillon, a former French county.

Perrault, Charles, a French author, was born at Paris, 12th January 1628, studied at the College of Beauvais, left it suddenly because he was rebuked by a professor, devoted himself diligently to private reading, and passed as an advocate in 1651. From 1654 to 1664 he remained in the office of his brother, who was receiver-general of finance, and obtained the friendship of Colbert, upon whose recommendation he was received into the Academy (1671). P. threw himself with great ardour into the study of architecture, sculpture, and painting, and by his influence the new Academy, devoted to these subjects, was organised. During this period he composed light, poetical pieces, but it was not till 1687 that his *Le Siècle de Louis le Grand*, an indifferent poetical harangue, attracted attention. In it he supported the thesis that contemporary writers were superior to the greatest of the ancients. The hot discussion to which it gave rise encouraged him to continue the subject in *Parallèle des Anciens et des Modernes*, published between 1688 and 1698, in which, by dialogue, he maintained the superiority of the modern world, not only in literature, but in science, philosophy, medicine, and cookery. The dialogues are conducted with much vivacity and ease, and, notwithstanding the theme, are wholly free from pedantry; they did not, perhaps, prove their case, but they helped to destroy the superstitious belief in the superiority of classicism. In 1694 followed *Apologie des Femmes*, in verse, a response to an attack of Boileau. Following up his glorification of the modern age, P. wrote his *Hommes Illustres du Siècle de Louis XIV.*, a collection of brief biographies of contemporaries. *Contes des Fées*, which succeeded it, were written for children in a style of the most exquisite simplicity, and by them alone he retains his place among authors who are read. P. was engaged upon a volume of *Mémoires* when he died at Paris, 16th May 1703. See *Mémoires*; St. Beuve's *Causeries du Lundi*, vol. v. P. had three brothers, of whom **Claude** (1613-88) was the most notable. He was first a physician and afterwards an architect, translated Vitruvius, and wrote *Essais de Physique* and *Mécanique des Animaux*.

Perron, Jacques Davy du, born at Saint Lo, Normandy, November 15, 1556, was educated at Switzerland, passed from school at ten, and at twenty was a *savant* in Latin, Greek, Hebrew, mathematics, and philosophy. Presented by Count Mantignon to Henri III., and by Henri to the poet Desportes, he was persuaded to abjure Protestantism for Roman Catholicism, and he was soon preaching eloquently before the king. Henri IV. appointed him Bishop of Evreux. For his success in converting the king to Catholicism, and for other services to the Church, he was appointed successively Archbishop of Sens, Grand Almoner and Commander of the Order of the Holy Ghost, and Cardinal. In his threefold character of poet, controversialist, and pamphleteer, he was one of the leading men of the age. He died at Paris, September 5, 1618. His works, of which the principal is a *Treatise on the Eucharist*, were printed in 1620. See the Abbé Ferret's *Le Cardinal du P., Orateur, Controversiste, Ecrivain: Étude historique et critique* (Par. 1877).

Perry, a fermented drink prepared from pears in precisely the same manner as Cider (q. v.) is made from apples. P. is a wholesome, pleasant beverage, containing from 5 to 9 per cent. of alcohol.

Per'sea. See AVOCADO PEAR.

Persecutions of the Christian Church. According to the Roman idea that religion was inseparably connected with politics, or rather was subordinate to the state, which was regarded as the centre of all human interest, it was impossible that the Christian religion, which substituted for the state a universal kingdom of God, embracing and superior to all human politics, could be treated with toleration. Besides, the bringing in of new divinities was always associated, in the eyes of the government, with the adoption of foreign laws and with treasonable practices; and as the brotherly love which formed a bond of union among all Christians wherever they met was unintelligible to their Roman rulers, they were specially liable to the suspicion

of forming secret compacts. But the existing laws against new religions were not always enforced, and least of all by the worst of the Emperors, who were most indifferent to the welfare of their subjects. The fact seems very anomalous to Christians that the Church was most persecuted by the best of the Roman Emperors; but it was only consistent in men with a high sense of duty to seek to stamp out what they must have considered a fatal and impious delusion. The case of Nero is no exception, since his cruelty was not directed against Christians for what they were, but for an accidental cause. Besides persecution was often forced upon the government by popular clamour excited by individuals—priests, magicians, craftsmen, &c.—who would be losers by the gain of Christianity (cf. Acts xix. 23-41). There is ground for believing that both the number of so-called P., and the number of Christians who suffered death for their religion, have been magnified. Sulpicius Severus (died about 422), believing (from Rev. xvii. 12-14) that it was decreed the Church should pass through ten P., made the nine which are mentioned by Eusebius up to that number by adding the future reign of Antichrist. The nine generally enumerated are as follows:—Under Nero, 64, Domitian, 95, Trajan, 106, Marcus Aurelius, 166, Severus, 202, Maximin, 235, Decius, 249, Valerian, 258, Diocletian, 303. As to the number of persons, too much need not be made of the palpable exaggeration of the tradition regarding the 10,000 crucified by Trajan, but Origen (q. v.), himself a martyr, distinctly declares (*Cont. Cels.*, about 220), that 'those who have been put to death on account of Christian godliness are comparatively few, and very easily counted.' See Neander's *Gesch. der Christl. Rel. und Kirche* (Eng. trans. 1858), Mosheim's *Ecl. Hist.* (Reid's ed. Glasg. 1848).

Persepolis, anciently the capital of the Persian monarchy, was situated at the eastern end of the plain of Mardusht, at the foot of high hills trending N. and S., near the confluence of the Araxes (*Bendémir*) with the Medus (*Pulwar*). According to ancient writers, it was surrounded by a massive triple wall, and was, next to Susa, the richest city of the Persians, containing a palace of unrivalled magnificence. All that remains of it now is included within the limits of the solid stone platform, measuring about 1500 by 800 feet, on which stood the halls and tombs of the Achemenian kings. This platform is constructed of immense blocks fitted to one another without cement, and is in the form of three terraces, of which the central is 45 feet above the level of the plain. The most prominent object which meets the eye of the traveller as he approaches P. after crossing the Bendémir is the grand double staircase, forming the ascent on the northern side of the platform, where the height is about 35 feet. This staircase, said to be the finest in the world both as regards proportions and construction, is built of syenite blocks, some of which are so huge that three or four steps have been cut out of the same stone. The steps are 22 feet wide, each step rising only 3½ inches, with a tread of 15 inches, and the great weight and hardness of the stones used have preserved their position and outline almost unaltered. There only remains standing upon this northern terrace the two short walls, known as the Propylæa of Xerxes, which no doubt formed the principal entrance to the Great Hall. These propylæa, which stand directly in front of the top of the grand staircase, are about four yards apart, and are each finished towards the entrance with the figure of a winged bull, immediately suggesting that connection between Persian and Assyrian art which the history of P. shows to have existed. The stairs leading from this level to the central terrace are very much smaller in all dimensions than the great staircase, but are remarkable for the beauty and finish of the sculptures with which the sides and angles are adorned. The central platform is about 800 feet square, and exhibits traces of five different structures—the Great Hall of Xerxes, the Hall of the Hundred Columns, the Palace of Darius, the Palace of Xerxes, and what has been termed by Fergusson the 'Central Edifice.' Of these, the Hall of Xerxes, which bears the local designation *Chehil Minar* (Forty Columns), is the most important, and is computed to have covered an area of 2½ acres. The ruins, which are here thickly scattered about, exhibit characteristics of several different styles and afford an interesting proof of the continuity of architecture. Fifteen columns of grey marble still remain standing, measuring 60 feet in height and 15 in circumference. They are fluted in 15 divisions, and their pedestals, suggestive in their bulbous form of Assyrian and Egyptian archi-

teature, are ornamented with the Grecian honeysuckle and ivy leaf. In the remains of the north entrance, several of the capitals bear a distinct resemblance to the Ionic volute, while close by are to be seen genuine Oriental bas-reliefs. These bas-reliefs and the cuneiform inscriptions, of which translations have been published by Sir Henry Rawlinson, are remarkable for their delicate chiselling and fine preservation. See Niebuhr's *Reisebeschreibung von Arabien und anderen umliegenden Ländern* (1774); Ker Porter's *Travels in Georgia, Persia, &c.* (1821); Fergusson's *Palaces of Nineveh and Persepolis Restored* (1851); Vaux's *Nineveh and Persepolis* (1851); Rawlinson's *Five Great Ancient Monarchies* (1871); and Meyer's *Remains of Lost Empires* (1875).

Perseus, a mythic hero of ancient Greece, was the son of Zeus by Danaë, and the grandson of Acrisius, king of Argos. The Pythian oracle had foretold that if Danaë had a son, he would kill his own grandfather; and accordingly when Danaë, despite all precautions, had given birth to P. (see **DANAË**), Acrisius locked them both in a chest, which he cast into the sea. This was driven by the winds to the island of Seriphos, where Danaë and her child were received as slaves into the household of King Polydectes. The latter, however, having failed after the most persistent efforts to win the love of Danaë, had recourse to various acts of cruelty, and ordered P., who had now reached manhood, to bring him the head of the Gorgon Medusa, who dwelt on the seashore near Tartessus. P. proceeded first to the Graæ, the sisters of the Gorgons, and forced them to show him the way to the ocean nymphs, who supplied him with winged sandals, a bag, and the helmet of Hades, which rendered the wearer invisible. Hermes also gave him the sword of Apollo Chrysaor, while from the goddess Athena, with whom Medusa had dared to contend for the prize of beauty, he received a polished shield by the reflection from which he might see the Gorgon without looking at her, as every one who beheld her face was instantly turned into stone. Thus prepared, he succeeded in slaying Medusa while she lay asleep with her two sisters. He then placed her head in the bag, and began his journey homewards. On his way he met with several wonderful adventures, and as he passed through Ethiopia he rescued Andromeda (q. v.), whom he married, and with whom he returned to Seriphos. There, at a banquet, he suddenly uncovered the Gorgon's head before Polydectes, who, with his followers, was turned into stone. P. then sought out Dictys, the fisherman who had saved him and his mother from the sea, and made him king of the island. After giving his winged sandals to Hermes, and the Gorgon's head to Athena, who placed it on her shield, he set out for his native Argos. But when Acrisius heard of his approach, he remembered the warning of the Pythian oracle, and fled to the court of the king of Larissa. Thither P. followed him in affectionate haste, to persuade him to return without fear. By doing this he unintentionally fulfilled the prediction, for at some games which the king of Larissa held in honour of his guest, a quoit thrown by P. was diverted by the wind so that it struck his grandfather and killed him. It is said that P., in grief for what he had done, surrendered the throne of Argos to his kinsman Megapenthes, in exchange for that of Tiryns, where he died. In Grecian art the figure of P. greatly resembles that of Hermes.

Perseus, or **Perses**, the last king of Macedonia, and eldest son of Philip V., was born towards the end of the 3d c. B.C., and succeeded to the throne B.C. 179. The growth of the Macedonian power, during his father's lifetime, had long been regarded with jealousy by the Romans, and in 171 the Senate declared war against P. Had the latter possessed the boldness and energy of his father he might have effected a series of rapid and brilliant victories, since Philip, who had foreseen this contest, left the kingdom fully prepared for it. But instead of utilising his advantages by a sudden invasion of the Roman territory, P. allowed the first two years of the campaign to pass without taking any decisive action. In the meantime L. Æmilius Paullus (q. v.) took command of the imperial forces, and soon made the influence of his military genius perceptible. At the battle of Pydna, 22d June 168 B.C., the Macedonian army was totally routed. After having been led to Rome in triumph by his successful enemy, P. was permitted to spend the remainder of his life in an honourable captivity at Alba, where he died about three years later. His

character betrays great signs of weakness, and is defaced by an extreme jealousy and avarice, which hampered his policy on all sides, and lost him many allies.

Perseverance of the Saints is an article of the Calvinistic and Augustinian theory of salvation, which is thus stated in the Westminster Confession:—"They whom God hath accepted in his Beloved, effectually called and sanctified by his Spirit, can neither totally nor finally fall away from the state of grace, but shall certainly persevere therein to the end, and be eternally saved." The doctrine is a necessary inference from the other Calvinistic doctrines of Election (q. v.), of the Covenant of Grace, of the union of Christ with believers, in its federal, spiritual, and vital aspects, of the Atonement (q. v.), of Justification (q. v.), of the indwelling of the Holy Spirit, and of the prevalence of Christ's intercession. P. is a point on which both the Roman Catholic and the Arminian creeds differ from the Calvinistic. According to both the former, a man may be justified, and yet afterwards fall from grace, and be finally lost. See Hodge's *Outlines of Theology* (Edinb. 1870).

Per'shore, a market-town of England, in Worcestershire, on the Avon, 6 miles W. of Evesham by rail, has two churches, St. Andrew's and Holy Cross (restored 1864), two banks, one newspaper, and engineering and machine-works. Wool-stapling is the leading industry. Pop. (1871) 2826.

Per'sia, a country of Western Asia, is bounded N. by Turkestan, the Caspian Sea, and Russian Transcaucasia, W. by Armenia, Kurdistan, and the Tigris district of Asiatic Turkey, S. by the Persian Gulf, and E. by Beluchistan and Afghanistan, in lat. 25° 40'–39° 50', and in long. 44° 20'–61° 35'. Its extreme length, from Khoi in the N.E. to Gwadar in the S.W., is 1400 miles; and its breadth, from the river Atrak in the N. to the Makran coast in the S., 900 miles. The area is estimated at 636,900 sq. miles, and the pop. at six or seven millions, but no census having ever been taken, the accuracy of these figures cannot be guaranteed. The great divisions into provinces are as follows:—

- | | | |
|----------------|-----------------|--|
| 1. Azerbaijan. | 10. Khuzistan. | |
| 2. Gilan. | 11. Ispahan, | |
| 3. Mazanderan. | 12. Nain, | |
| 4. Astrabad. | 13. Tehran, | |
| 5. Khorasan. | 14. Khemseh, | |
| 6. Yazd. | 15. Mullayer, | |
| 7. Kirman. | 16. Ardalan, | |
| 8. Laristan. | 17. Kirmanshah, | |
| 9. Fars. | 18. Luristan. | |
- } Irak Ajami.

Physical Features.—P. occupies the western and larger half of the Iranian plateau between the valleys of the Indus and the Tigris. This plateau on the W. is united with the mountains of Asia Minor by the Armenian highlands, and on the E. connected with the Himalayas and the highlands of Tibet by the Paropamisus and the Hindu Kush. Its average height above the sea is 4000 feet, varying from 8000 in some of the outer valleys to 500 in the most depressed portions of the centre. Its greater elevation at the edges, and the fact that less than half its surface drains outwards to the Persian Gulf, the Caspian, and the Aral, indicate the basin-like nature of the plateau. The part draining inward consists of two sections, the eastern, draining into the Hamoon, or Lake of Seistan, embracing 40,000 sq. miles, and called from its chief river the Helmund basin, the western, draining into many depressions of the surface, and covering 320,000 sq. miles. P. has no great rivers. In the Caspian watershed are three considerable streams—the Kizil-Uzun, or Safid-Rud, draining 25,000 sq. miles E. and S. of the Urmia basin, the Atrak forming for its last 60 miles the boundary between P. and Turkestan, and the Gurgau. In the S.W. are the Dizal, and Karkah, flowing to the Tigris, further S. the Diz and Karun unite in the plain of Khuzistan and discharge into the Shat-el-Arab, in the district of Arabistan—the most fertile plain in P. The chief inland streams are the Aji Chai and Jaghatu, flowing into Lake Urmia, the Hamadan Rud or Karasu, and the Shurnab, flowing E. to the salt desert, the Zaindardut, fertilising the neighbourhood of Ispahan, and lost in the unexplored salt marsh of Gavkhanah, and the Kur, better known as the Bendameer, forming the salt lake of Niziz. The two chief mountain systems in P. are (1) the Elburz in the N., which runs parallel to the southern shores of the Caspian, and forms the connecting link between the Hindu Kush in the E. and the

Caucasus in the W.; (2) the Persian Gulf range, which is an offshoot or continuation, in a S.E. direction, of the Zagros mountains. Besides these there are numerous small spurs penetrating the central desert. The highest continuous range is the Kuh Dinar in Fars, with an average height of 17,000 to 18,000 feet above the sea. The volcanic peak of Demavend, in the Elburz, has been fixed by the Russian Caspian survey at 18,600 feet, and Mount Savalan in Azerbaijan at 14,000 feet. The higher summits of the Kuru range, between Ispahan and Kashan, exceed 11,000 feet, a height equalled by the peaks of the Khorasan Mountains. The plains between the ranges on the E. side of the western watershed rise from 1000 to 8000 feet high, and farther S. and E. to 4000, 5000, and 6000 feet. The largest desert in P. is that of Khorasan, extending from Kum and Kashan E. for 300 miles. The desert of Kirman stretches from Khubes to the Lake of Seistan, 150 miles, and runs S. to near the Persian Gulf. The salt-swamps of P. are the most remarkable feature of the country. The soil of the plateau is of such a nature as to form an efflorescence of salt upon the surface whenever exposed to sufficient moisture, by the overflow of rivers, or by want of sufficient slope to carry off the desert rainfall, the moisture, however, being retained underneath the surface to create in winter and spring an impassable bog. When the supply of water is constant, but insufficient to form salt lakes like Urmia and Niz, bogs of slimy mud are formed, covered with brine in winter, and in summer with a thick crust of salt. These are termed Kuvir in the N., and Kafeh in the S. The chief is the Dashti-Kuvir ('Great Salt Desert'). It is described by Dr. Buhse, the only European who has crossed it, as being 6 miles wide. Other Kuvirs are in the Sarjan, or Sarabad plain W. of Kirman, and in the valley of Kutru S. of Khaf.

Climate, Botany, Zoology, and Agriculture.—No country has greater diversity of climate than P. In the provinces of Laristan, Kirman, Fars, and Khuzistan, between the edge of the plateau and the Persian Gulf, the heat in summer is excessive. The climate improves as we proceed N., and Ispahan, the former capital of the country, has the most equable temperature of any town in P. The northern cities of Irak-Ajami, however, do not enjoy so favourable a climate, the cities of Kashan and Kum on the verge of deserts, and Tehran under the Elburz mountains having a summer heat as oppressive as the shores of the Persian Gulf. The rainfall on the Oceanic and Caspian watersheds is far in excess of that in the interior, that of Ghilan and Mazandaran being five times that of the districts S. of the Elburz range. In central and S.E. Persia, the annual rainfall does not exceed five inches. The prevailing winds are N.W. or S.E., the latter being the rain-bearing winds throughout the greater part of P. The nature of the soil varies as much as the climate; in the S. and E. it is light and sandy, in the W. and interior hard and gravelly, and in the district bordering on the Caspian, rich and loamy. Almost all the cultivation depends on artificial irrigation, either by canals or by the system of wells connected with underground channels, called *Kanat* or *Karez*, and peculiar to the Iranian plateau. Rice, wheat, and barley are raised, besides cotton, indigo, and tobacco, and in most districts, apples, pears, cherries, apricots, peaches, melons, quinces, grapes, and pomegranates. The chief trees are the mulberry, sycamore, walnut, cypress, conar, and poplar. Cucumbers, turnips, cabbages, carrots, potatoes (recently introduced, but thriving well), poppies from which opium is extracted, senna, rhubarb, saffron, and assafoetida are also grown. Agriculture is in a very depressed state, and the rudest implements are still in use. The fauna of the Persian plateau is of the desert type, with a large admixture of Palearctic forms; that of Beluchistan and the shores of the Persian Gulf is of the same type, with a small admixture of Indian species. They include the lion, jackal, wolf, fox, hare, wild ass, wild sheep, mountain goat, wild hog, jerboas, and antelope. The flesh of the wild ass is considered a great delicacy. The domestic animals are the horse, mule, camel, ass, ox, and sheep, and the various kinds of European poultry. Bustards, black partridges, and quails are hunted. Locusts, snakes, and scorpions infest the S., and in Miana and Todervar an insect is found called the shah-gaz (*Argus Persicus*) with a very poisonous bite. Fish of all kinds are abundant in the Caspian, and there is considerable fishery of sturgeon, salmon, and carp.

Geology and Mineralogy.—The most striking feature of the geology of P. is the great prevalence of gravel, sand, and

clay formations, which are the more conspicuous from the paucity of vegetation and the absence of cultivation. The Zagros chain (from Ararat to Shiraz), consists of Cretaceous (hippuritic) and Tertiary formations, the former in the N.E. half of the range has its slope towards the central plain of P., the latter on the S.W. watershed overlooking the Tigris valley. Old granite rocks extend from Lake Urmia to the W. of Ispahan. The N.W. and S.E. ridges have the same features as the Zagros. The S. borderland of the great plateau consists of low ranges, running E. and W., composed of unfossiliferous sandstones and shales, with a few beds of nummulitic limestone of the older Tertiary epoch. In the N.W. older Mesozoic and Paleozoic formations are found than in the W. or S. The Elburz consists of Carboniferous and Devonian beds, with Jurassic or Liassic rocks. Metamorphic rocks (granite, &c.) occur in several places, and igneous formations occupy a considerable area. The highest mountain in P., Demavend, in the Elburz chain, is a volcano of geologically recent origin, which still issues heated gas. Scarcely any attempt has been made to utilise the mineral wealth of P., which, though not great, includes iron, copper, and silver in Azerbaijan, Mazandaran, and Kirman, lead in Yazd and Azerbaijan, silver near Shiraz, abundant coal near Shiraz and Hir N.W. of Tehran, marble at Maraga and Khorasan, turquoises at Mishapur, besides sulphur and saltpetre in the mountains N. of Tehran, and the latter also in Azerbaijan.

Industries, Commerce, &c.—The whole external trade of P. may be estimated at the value of £4,000,000 sterling annually, of which the imports amount to £2,500,000, and the exports to £1,500,000. The chief articles of import are cotton goods, glass, paper, iron, copper, sugar, tea; of export, silk, tobacco, skins, wood, carpets, shawls, opium, copper and lead ores, and sulphur. Tabriz is the centre of commerce, being favourably situated as an emporium for the productions of N. India, Samarcand, Bokhara, and Cabul. It receives European goods through Constantinople by sea to Trelizond, and thence by caravan. In 1875 there entered P. through this town cotton goods of British manufacture to the value of £800,000, while £110,000 worth of silk were exported to France and Spain. The direct exports of P. to Britain in 1875 were chiefly opium to the value of £24,930, and imports chiefly cotton goods to the value of £37,895. The visit of the Shah to Europe in 1873, and his concession to Baron Reuter, gave rise to great expectations of advancement in civilisation. It granted him the sole right of making railways for seventy years, and the working of all Government mines subject to paying 15 per cent. of profits to the State, the management of the forests and canals, the collection of all customs for twenty-five years, and the first choice in the making any work for the improvement of the country or the setting up of any bank, with a grant of £6,000,000 from the Government; but he has not yet been permitted to commence his undertaking, from the jealousy of the Persians and the intrigues of the Russians. P. has a system of telegraphs worked by Europeans. At the end of July 1876 there were 2490 miles of telegraph lines with 46 telegraph offices. The number of despatches in 1875 was 675,000, and the revenue from them £14,000.

Government, Finance, Army.—The government in its main features is similar to that of Turkey. It is a pure despotism, but the absolute power of the Shah is limited by the precepts of the Koran, and their interpretation by the priests. The executive is carried out by the Vizier-i-Azem or Grand Vizier, and the Ameen-ed-Doulah or Lord Treasurer, under whom are the Beglerbegs or Governors of Provinces, which are subdivided into districts under a Hakim or Governor-Lieutenant, next the Thaubet, who governs a city or town, and the Kelounter, who is found in every village, town, and city, collects the revenues, and is the medium of communication between the people and the Shah. Towns elect a Ketkhodah, or magistrate, with his servant, or 'homme-d'affaires,' the Pak-Kar, and villages a Muhuleh for the administration of justice and regulation of local matters. The revenue amounted in 1876 to £1,643,200, of which £1,388,800 was paid in money and £254,400 in kind, and of which direct imposts yielded £1,240,000, and customs £200,000. The expenditure amounted to about 1½ millions, of which the army took £678,400, expenses of the royal court £307,200, the clergy £240,000, pensions to great families, the Afghans and others, £80,000, foreign affairs £28,000, other services £60,000, education £12,000. There is no public debt, and the excess of revenue is deposited in the royal treasury.

By a decree issued July 1875, the army for the future is to be raised by conscription, and service to be for twelve years instead of for the whole life of the soldier, as before. The regular infantry consists of ten divisions of ten regiments, each regiment containing 830 men, making a total of 83,000 men, armed with old percussion muskets. The *chasspors* bought in France, or made in the arsenal at Tehran, have not yet been given to the troops. The only regular cavalry is the guard of the Shah (500 men), but in time of war each province is required to furnish a certain number of irregular horse, of which the country can raise 25,000 to 40,000 men, all well mounted. The artillery is composed of ten regiments, with three or four batteries, each of 18 to 24 cannon: total, 5000 men and 200 cannon; the latter, however, are small and of different calibre. The militia, numbering 20,000 men, are only employed as police. Christians, Jews, and Guebres are exempt from all military service.

Religion, Education, &c.—The great majority of the inhabitants are Mohammedans, only 74,000 professing other faiths, of whom 26,035 are Armenians, 25,000 Nestorians, 16,000 Jews, 7190 Guebres. The Persian Mohammedans, called Shiites or Shiabs (q. v.), differ from the Turkish, who are called Sunnites (q. v.), in some respects, as regards doctrine and ritual. The chief order of priests is the Mushtehed; next in rank is the Sheikh-ul-Islam, or ruler of the faith, of whom there is one paid by the State in every large town. Under these are the Muturrelle, one in each mosque, the Muezzin, or sayer of prayers, and the Mollah, or conductor of rites. Education is more widely spread than in any Asiatic country, except China. There are many State-supported colleges, where instruction is given in Persian and Arabic literature, religion, and science.

Inhabitants.—The population of P. mainly consists of two great divisions—the *Tajiks* or settled inhabitants and the *Eylats* (q. v., 'clan') or nomads. The former are descendants of the ancient Persians, Medes, and Bactrians, and prosecute agriculture, commerce, and the arts; the latter are of four races—Turkomans, Kurds, Lûurs, and Arabs. Of these the Turkomans are the most powerful; the Lûurs are of purely native origin. They are all predatory in their habits, but are generous and hospitable. They carry on an uncertain commerce with the towns, and probably amount to one-third of the entire population. There are some 25,000 native Christians, 15,000 Jews, and 6000 Guebres (q. v.), the last residing chiefly in Yezd.

History.—In the legendary *Shah-Namâh* of the poet Firdusi the history of P. is given from the earliest times, the first king being Kaiomurs, great-grandson of Shem, surnamed Paishdad ('just judge'). He founded the Paishdadian dynasty, and was followed by Hushang, Jamshid, Feridun, Zab, and Kershasp, the last slain by Afrasiab, king of Turan, who, however, was driven beyond the Oxus by the heroic Rustam, who set upon the throne Kai Kobad, supposed to be the Deïoces of the Greek writers. Kai Kobad founded the Kaianian dynasty, and was succeeded by Kai Kaus, the Cyaxares of the Greeks, and the Arphaxad of the Book of Judith, and by Kai Khusrû, the Cyrus the Great of the Greek historians. Under him the Median element, predominant in P. since the reign of Cyaxares, became subject to the native Persian, and the Medes are not afterwards heard of as having a separate existence. He conquered Turan, Syria, Asia Minor, and Egypt, and was followed by his son Gushtasp, the Darius Hystaspes of the Greeks, whose attempts to conquer Greece were frustrated on the plain of Marathon (490 B.C.), as those of his son Xerxes at Salamis and Platæa. In the reign of Darius appeared Zoroaster (q. v.), the great reformer of the religion of Iran. In 465 B.C. succeeded Bahmân or Ardeshir Dirazdust ('long-handed'), the Artaxerxes Longimanus of the Greeks and the Ahasuerus of the Jewish Scriptures. He was followed by Darab I. and Darab II., the Darius Codomannus of the Greeks, with whom the Kaianian dynasty came to an end by the conquest of Alexander the Great. At the death of the latter in 324 B.C., Seleucus Nicator, the most able of his generals, seized Syria and P. He was followed by Antiochus Soter and Antiochus Theos, in whose time Arsaces, called by the Persians Arshk, slew the viceroy Agathocles, threw off the Grecian yoke, and founded the Parthian Empire, which consisted of a confederacy of free feudatories called the Muluk-ul-Sawaif ('Commonwealth of Nations'). Such were the Parthians, who stemmed the torrent of Roman conquest in the East, and often, as in the case of Crassus, inflicted on the Romans terrible defeats. They

are called by Strabo Carduchi ('Kurds'), and their yoke being a barbarous and degrading one, they are scarcely mentioned by Firdusi and the other Oriental writers. (See ARSACIDÆ.) In 228 A.D., Ardeshir, a descendant of the ancient Kaianian kings, killed Arduan, the last of the Parthian princes, and was hailed on the battle-field as Malkan Malka ('king of kings'). He founded the Sassanian dynasty. He was succeeded by Shapur (240 A.D.), who fought successfully with the Romans, and took their Emperor Valerian prisoner. Among the other notable Sassanids were Varahran I., who caused Manes, the founder of the Manichæan heresy, to be executed; Nersehi, who waged a long warfare with the Romans; Shapur II., under whom the empire reached a state of great prosperity, and Varahran V., who was one of the best monarchs that ever ruled P. He fought successfully with the Roman Emperor Theodosius, and inflicted terrible defeat on the predatory hordes of Turan. Nushirvan, as famous for his justice as his conquests, died in 578, leaving an empire extending from the Red Sea to the Caspian, from the Black Sea to the Jaxartes, and from the Mediterranean to the Indus. He was succeeded by Hormazd IV., who was dethroned by his son, Khusrû Parviz, who conquered Egypt, Syria, and Asia Minor, and threatened Constantinople for ten years by a camp on the Bosphorus. In the midst of his prosperity he received a letter from Mohammed, in which the latter claimed recognition as the prophet of God, to his impious rejection of which are ascribed all his subsequent disasters by the Arab historians. He was murdered by his son Shiruyah, soon after his disastrous defeat by the Roman Emperor Heraclius. In 632 Yezdegird III. ascended the throne, and was defeated in 636 at El-Kadinyah by the Saracens under Saad ibn Abu Wakkas, in a desperate battle which lasted three days and nights, and again in 641 in the decisive battle of Nevehend. The Arabs now conquered the whole country, and P. became a part of the empire of the Califs. After the murder of Ali, Moawiyah, son of Abu-Sofian, setting aside the claims of the sons of Ali, carried the seat of government to Damascus, and changed the rude austerity of the early Moslems for the gorgeous pomp of Eastern potentates, while he introduced the arts and sciences of the civilised world. He was followed by his son Yezid, in whose reign Husain, the son of Ali, was defeated and slain on the field of Kerbela, 680. But a numerous body of believers in P. declared Ali and his successors to be the true Imams, and that this belief constitutes the most important article of the faith. Accordingly they refused to accept the *Sunnah*, or body of traditions given forth by Abu-Bekr, Othman, and Omar, and expected the restoration of the race of Ali, who, however, was cursed regularly from the pulpits of the orthodox, a custom discontinued by Omar, grandson of the third Calif. The last of the Omniad dynasty was Merwan II., who was dethroned by the Abbasides (q. v.), who set up Es-Saffah. He was followed by Abu-Jaafar-el-Mansur, who made Bagdad his capital. The greatest of the Abbaside Califs was Hârun-al-Rashid (q. v.). Succeeding monarchs lost the warlike virtue of their ancestors, and saw Spain, Africa, Egypt, P., and Syria torn from their grasp, while they trembled at the menaces of their licentious Turkish guards. The distant lieutenants began to aspire to independence, and many of them founded dynasties, of which the chief in P. were the Saffary or Brazier dynasty, founded in 868 by Yakub-bin-Lais, son of a brazier in Sistan, who conquered Balkh, Cabul, and Fars; the Samany dynasty, which Ismail Samany, a Tartar lord, founded on the ruins of the former, ruling Khorasan and the N. of P., with capital at Bokhara; and the Dailamy dynasty, ruling Fars and the S. of P., founded by Abul-Buyah, son of a fisherman at Dailam, on the Caspian, who seized Ispahan in 933, and received from the degenerate Calif, who wished to appear to bestow a power which he could no longer withhold, the title of Amîr-ul-Umara ('Chief of the Nobles'). Succeeded in 907 by his son Ahmed, and by his grandson Nasr, who acquired Ray and Kom, and died at Bokhara in 943. The Ghiznevide dynasty rose as rapidly as the Dailamy, and in 997 Mahmud (q. v.) mounted the throne. After his death the dynasty declined in power, and a torrent of Turkish invasion from the eastern shores of the Caspian overspread the country. In 1038 Togrul and Daud, the two grandsons of Seljuk, crossed the Oxus and defeated an army sent against them from Ghizni at Zandikan. From this time the Ghiznevide dynasty lost its power, but does not disappear until 1160, Togrul then advanced into Khorasan, assumed the title of king at Nishapur, conquered

all P., and entered Bagdad as a conqueror. Subsequently he acquired Mosul, and defeated the Greeks in several battles. His nephew, Alp-Arslan, in 1070 defeated the Greek Emperor Romanus Diogenes and took him prisoner. The last Seljuk king was Toghrul III., who fell (1193) fighting against the invading Tokush, ruler of Khuwarizm. P. was now divided between the king of Khuwarizm, who held Khurasan, and a number of petty princes, called Ata-begs, of whom the chief were those of Azarbaijan and Fars. These minor governments were all absorbed by the conquests of the Mongols under Genghis-Khan (q. v.). Jalalud-Din, son of the king of Khuwarizm, offered a brave resistance, but was defeated in 1221. Hulaku-Khan, the grandson of the conqueror, was sent to govern P. and extended his conquests W. He took Bagdad, and put to death the last Abbaside Calif, subdued Mosul and Mesopotamia, and fixed his residence at Maraghah in Azarbaijan, where he died in 1264. In 1303 Mohammed-Khudah-Bundah removed the seat of government to Es-Sultaniyyah. Abu-Said, who died in 1335, was the last of the Mongol dynasty who had any real power in P., his successors until 1344 enjoying merely a nominal sovereignty among petty chiefs who engaged in warfare among themselves, thus paving the way for the conquests of Timur (q. v.). During this period Fars was governed by the Muzhaffars, the last of whom, Shah Mansur, was put to death with all his family by Timur in 1387. This conqueror subdued in 1381 Khorasan and Mazanderan, next Seistan, Kandahar, Azarbaijan, and Georgia, and in 1387 entered Ispahan. During the five years which followed 1391, Timur completely subjugated all parts of P., and carried his victorious arms beyond the Caucasus. His son, Shah Rokh, who succeeded in 1408, fixed his capital at Herat. The race of Timur ceased to reign in Iran in the beginning of the 16th c. The Kurdish dynasties of Kara Koyunlu ('black sheep') and Ak Koyunlu ('white sheep') next acquired the sovereignty, but Shah Ismail Safi, the founder of the Safawi dynasty, restored a native monarchy in P. after it had been overrun for 850 years by the hordes of Turan, and by Arab, Turkish, and Mongol conquerors. Ismail consolidated the various factions of the country by proclaiming the doctrine of the Shiah sect to be the national religion. He carried on many successful wars, but was in 1514 defeated by Selim I., Sultan of Turkey. His successor was Tahmasp I., in whose reign arrived (in 1561) an envoy from Queen Elizabeth. The reign of Abbas the Great (1585-1628) is a splendid era in Persian history (see **ABBAS THE GREAT**). He was followed for nearly a century by a line of degenerate monarchs ending with Shah Sultan Husain, who was defeated (1722) under the walls of Ispahan, and deprived of his crown by Mahmud, chief of the Afghans. The latter died in 1725, after practising the most fearful cruelties upon the Persians. His son Ashraf was defeated in 1730 by Nadir Kuly, who, after dethroning Tahmasp II. and his son Abbas II., was proclaimed Nadir Shah (q. v.) in 1736, and ruled until 1747. On his death anarchy swept over P. The Afghans and Belucches asserted their independence, and many chiefs seized parts of the land; but in 1755 Kerim Khan, chief of the Zand tribe, raised Ismail III. to the throne, with Reshad, chief of the Bakhtiyari tribe, as commander-in-chief, and himself as *wakil*. In 1757 the government fell into his hands alone. He chose Shiraz as his seat, and did much to benefit the country. His death in 1779 was followed by the usual anarchy, during which Agha Muhammad Khan Kajar fled to Mazanderan, put himself at the head of his powerful tribe at Astrabad, and made successive attempts against Ali Murad, Jaafar Khan, and his noble but ill-fated son Lutf Ali Khan, who, betrayed by Hajji Ibrahim Kalantar ('chief magistrate') of Shiraz, after a heroic defence was taken at Bam and put to death. The dynasty of the Kajars now (1795) began to reign. The conqueror immediately transferred the seat of government to Tehran, which was in the neighbourhood of his native provinces. He turned his arms against Georgia, which had transferred its allegiance from P. to Russia in 1783 during the distracting Zand and Kajar wars, took Tiflis before the Russians could advance to its relief, and soon conquered the whole province. He next turned his arms against Khorasan and projected the conquest of Bokhara, but he was murdered in 1797. His successor was his nephew Fateh Ali Shah, with whom the government of India, alarmed at the intrigues of Tipoo Sultan of Mysore with Zaman Shah of Afghanistan, made a commercial and political treaty. For the first seven years of his reign the Shah had been occupied in quelling rebellions in different

parts of his empire, but in 1804 he was able to turn his attention to the Russian advances on the W. frontier, where General Zizianoff had taken the provinces between Georgia and the Caspian. The Russian general was assassinated at Baku in 1805, and Russia until 1813 was too deeply engaged in the affairs of Europe to push her conquests further. Meanwhile the Shah, after vainly soliciting British aid, made overtures to France, and Napoleon had made an alliance and despatched French officers to discipline the Persian forces, but the Shah, to whom Napoleon had promised the restoration of Georgia in the event of a treaty being made between France and Russia, finding that stipulation omitted in the treaty of Tilsit of July 1805, again embraced the British alliance, and in 1811 a definitive treaty was concluded. Hostilities still went on on the Russian frontier, and in 1812 a Persian army under Abbas Mirza was cut to pieces on the banks of the Araxes. In 1813 the treaty of Gulistan was concluded, by which P. ceded to Russia all the territory she had conquered, including Georgia, Immeretia, Mingrelia, Derbend, Baku, and all Persian Daghestan, Shirvan, Sheki, Ganja, Karabagh, and parts of Moghan and Talish, while she engaged to maintain no navy on the Caspian. During the war with Russia, rebellions had broken out in various provinces of P., particularly in Khorasan, which Firoz-ud-din, prince-governor of Herat, had fomented. Accordingly in 1816 Hasan Ali Mirza, the new governor of Khorasan, led an army to Herat and terrified its governor into surrender and payment of an indemnity. Next year he led another expedition against Herat, but the government of Cabul intervened, and Fateh Khan, vizier of Shah Mahmud of Afghanistan, defeated him. In 1821 a war broke out between P. and Turkey, which was terminated in 1823. As the differences between P. and Russia arising out of the treaty of Gulistan had never been settled, in 1825 Russia took possession of Gokcheh as security. In December of that year the Czar Alexander died, and Nicholas succeeded to the throne. Meanwhile a religious movement against Russia had sprung up in P., and the government was obliged to give its consent to war, the management of which was given to Abbas Mirza, the heir-apparent. In spite of some temporary successes, the result was most disastrous to the Persians, who in 1828 agreed to the Treaty of Turkmanchai, by which the Khanates of Erivan and Nakhichevan were ceded to Russia in perpetuity, while P. paid an indemnity of nearly £4,000,000, and bound herself to maintain no armed vessels on the Caspian, which was thus converted into a Russian lake. In 1828, the infuriated mob of Tehran rose in revolt and murdered the Russian ambassador and his staff—an outrage the consequences of which were only averted by the most humiliating apologies. In 1829, cholera, followed by a famine, ravaged P. and carried off in Ghilan alone 200,000 souls. Abbas Mirza subdued the rebellious inhabitants of Khurasan, and was preparing to lead an expedition against Herat, when he died, October 21, 1833. Muhammad Mirza was immediately declared Wali Ahd ('heir-apparent'), and succeeded Fateh Ali Shah on his death, October 23, 1834. Russian influence was now predominant at Tehran, and in 1837 the Shah in person led an army against Herat. The siege commenced 22d November and continued until the withdrawal of the Persians, September 9, 1838. Its gallant defence was mainly due to the exertions of Pottinger, a young English officer, and the siege was raised when the inhabitants were at the utmost extremity, by the protest of England and the appearance in the Persian Gulf of an English force. While the Persians were prostrated with their exertions, the Russians seized Ashurada, an island 12 miles from the Astrabad coast of the Caspian Sea, ostensibly to repel the piratical incursions of the Turkomans, but really to secure the Caspian to themselves and establish a basis for further aggrandisement. Towards the end of the reign a commission from the English and Russian governments settled the boundaries between P. and the Turkish Empire. Muhammad Shah died 4th September 1848, and was succeeded by Nasru-d-Din, the present Shah, who at his accession found P. in a miserable state of exhaustion and discontent. By the help of Mirza Taky, Amiru-n-Nizam ('commander-in-chief'), he was enabled to suppress all revolts, the most dangerous of which was that of the Babis, a sect of religious fanatics with wild pantheistic and socialistic principles; but, like his two predecessors, he repaid this by the foul murder of the enlightened and faithful vizier. In 1856, after grossly insulting the British mission, the Persians led an expedition against Herat, which fell October 26.

War was declared by England November 1, and an expedition sailed from Bombay and occupied the island of Karak. Bushire was taken and a severe defeat inflicted at Koshab on the 7th January 1857, after which General Outram led his army to the mouth of the Kurun. A treaty of peace, however, was signed at Paris, March 4, by which P. renounced all claims on Herat and agreed to abstain from all interference with Afghanistan. The anxiety which P. has always shown to extend her borders led to serious difficulties with the Afghans in 1866, but the final award of Sir Frederic Goldsmid, who was sent by England as arbitrator, was given August 19, 1872, and ultimately accepted by both governments. The boundary, however, N. of Khorasan, between Merv and the Caspian, is still unsurveyed, and its settlement in view of the recent extension of the Russian frontier to Khiva and the Oxus must be regarded as one of the most pressing Asiatic political questions. P. has made considerable progress during the last twenty years, notwithstanding the terrible famine of 1870-72 and the gross maladministration of its rulers. The expectations formed from the visit of the Shah to Europe in 1873 have as yet proved illusory, but something may be expected from the increasing intelligence and prosperity of the country and its closer contact with Western civilisation. See Blanford's *Eastern P.*, an *Account of the Persian Boundary Commission of 1870-72* (2 vols. Lond. 1876); Clement Markham's *General Sketch of the History of P.* (Lond. 1874).

Persian Gulf, an arm of the Indian Ocean, extending N.W. for 620 miles between Persia and Arabia, with a breadth of from 27 to 207 miles, and communicating with the ocean by the Straits of Ormuz, 27 to 50 miles wide. Its entrance is formed on one side by the long promontory of Ras Musandim with two isolated rocks called the Quoins, and on the other by the Island of Ormuz (q. v.). It receives at its upper extremity the waters of the Shat-el-Arab, and contains the islands of Kishim, and on the Arabian side, Bahrein, near which are extensive banks of pearl oysters. The order of its current is the reverse of that of the Red Sea (q. v.), being upward from May to October, and downward from October to May. The chief towns on the Gulf are Bandar Abbas, Kamir, and Bushire. The trade of the Gulf was originally in the hands of the Portuguese, but afterwards fell to the Dutch and English. On the fall of the Portuguese, a powerful maritime Arab power arose on its shores, Oman or Muscat (q. v.) being the greatest native naval power in Asia. The Gulf was made known to the ancient world by Nearchus, the admiral of Alexander the Great, who sailed through it from the Indus B.C. 325, and it was afterwards the channel of communication for the most important commerce of the ancient world. It will again be of great importance when the Euphrates Valley Railway shall have been completed and the shortest route to India finally adopted, the route by the P. G. being 1104 miles shorter than that by Suez. The distances are as follows:—London to Suez 4372 miles, Suez to Karachi 1705, total, 6077; London to Bassora 4271 miles, Bassora to Karachi 702, total 4973.

Persia'ni, Madame Fanny, operatic singer, was the daughter of Signor Tacchinardi, a celebrated tenor, and was born at Rome, October 14, 1818. She was a leading soprano in the Italian Opera-Houses of London and Paris from 1838 to 1850. Among her greatest successes were in the operas of *Matrimonio Segreto*, *Lucia di Lammermoor*, *L'Elisir d'Amore*, and *Linda di Chamouni*. She excelled in light and sprightly characters.

Persian Language and Literature.—Modern Persian, the lineal descendant of the ancient Zend (q. v.), and consequently a member of the Aryan family of speech, is, after Arabic, the most important language of the Mohammedan world. The Arab califs destroyed all traces of Pehlvi poetry, as savouring of heathendom; and Arabic was the court language of Iran down to the conquest of the Seljuk princes (1038). Hence we are not surprised to find that Persian has incorporated in its vocabulary an infinite number of Arabic words, even forms its plurals by means of the Arabic feminine plural in *at* or *jat*, and has adopted the Semitic order of words, so repugnant to the Aryan structure generally, saying *dil-i-man*, 'heart of me' for 'my heart.' At the same time Persian has lost nearly all the ancient Zend inflections, and strikingly resembles English in the simplicity and analytical character of its grammar. It has no article,

does not distinguish gender in substantives or adjectives, and, though extremely rich in tenses, has only one proper mood, the indicative, forming its subjunctive and optative by means of particles. One of the most melodious of languages, it is peculiarly fitted for poetry, and has been aptly styled the 'Italian of the East.' Persian handwriting (*talik*) is a modification of the Arabic (*neskhi*), and of its thirty-one consonants nine are of Semitic origin. There are Persian Grammars by Sir William Jones (Oxf. 1771), Lumsden (Calcutta, 1810), Mirza Ibrahim (Eng. trans. Lond. 1841), Chodzko (Par. 1854), Spiegel (2 vols. Leips. 1856), and Vullers (2d ed. 1870); and Dictionaries by Richardson (Oxf. 1777), Handjeri (3 vols. Moscow, 1840-42), Vullers (3 vols. Bonn, 1855-67), and Palmer (Lond. 1875).

Persian literature dates from the Samanian dynasty (902-997), under whom the blind Rudaki composed his noble lyrics, translated by Malcolm in his *History of Persia*. Rudaki (about 961) commenced to versify the *Bustan Nameh* ('Garden Book'), but was murdered before he had written a thousand lines, and Firdusi (q. v.) completed the unfinished work under the title *Shah Nameh* ('Book of Kings'). This, the great national epic of Persia, is purely Aryan both in its language and subject-matter, but five Arabic words occurring on an average in every hundred verses, whilst its 'Feridun' and 'Zohak' are identical with the 'Thraetona' and 'Aji Dahaka' of the *Zend-Avesta*. Persian prose was first written by Tabari (838-922), author of a history of Persia down to the califate, but prose has never been so familiar to the genius of Persian literature as verse. The next great poet after Firdusi was Omar Kheiam (died 1123), whose *Rubaiat* or quatrains, with their strange blending of atheism and tender fancy, of manhood and cynicism, have been given to the West in the metrical translation of E. Fitzgerald (Lond. 1859). The *Kasidals* or odes of Anwari (q. v.), the astrologer (died about 1200), are still highly treasured by the poet's countrymen for their quaint conceits; as is the *Khamseh*, a collection of Sufistic poems, of Nizami (died about 1200) for its stateliness and teeming thought. But both were soon eclipsed by the *Bustan* and *Gulistan* of Saadi (q. v.), 'combining,' says M. de Meynard, 'the delicacy of Horace, Ovid's elegant facility, the caustic *verve* of Rabelais, and La Fontaine's *bonhomie*;' and by the *Masnavi* of Saadi's contemporary, Maulavi Rumi (died 1272), a work which by its wealth of legend, doctrine, and apologue has won the title of the 'Persian Koran.' Amidst the turmoil of the Mongol invasion the Sufi Hafiz (q. v.), Persia's mystic Anacreon, poured forth his burning odes, and Jami followed Firdusi in celebrating the loves of Yusuf and Zuleikha (Joseph and Potiphar's wife). Hafiz, Jami's nephew and pupil, author of the *Laila wa Mejunun*, was the precursor of an innumerable crowd of minor versifiers, all singing in altered keys the well-worn themes of an esoteric love and a wine that symbolised the raptures of piety. The improvisations of Karroglou, a robber poet of the 17th c., are alone remarkable for a certain rustic vigour; whilst the verses of Hakim Kaani, poet-laureate to the reigning Shah, exhibit some tincture of Western civilisation, though adhering to all the ancient traditions of the past. Not much Persian prose has yet been printed. In the field of history, Tabari's greatest successors have been Dshuwaini (died 1275), who wrote a history of Genghis Khan; Rashideddin (died 1320), who wrote a history of the Mongols; Cazwini (died 1351), author of the *Lubb-et-tawarikh* ('Pith of History'); and Mirkhond (died 1493), whose *Rausat us Safa* ('Meadow of Purity'), a history of Persia till 1471 A.D., was abridged by his son Khondamir, himself the author of the *Habib us Siyar* ('Biographer's Friend'). In fiction, ethics, and miscellaneous literature the standard works are Jelalud-din's *Akhlak i Jelali*, a treatise on moral philosophy; Kashifi's *Anwar i Suhule*, the Persian version of Bidpai's fables; the collection of *The Thousand Fanciful Tales*, known to have existed from the 10th c., and which formed the nucleus or basis of the Arabic *Alf Laila* or *Book of the Thousand and One Nights*; Jami's *Beharistan* ('Spring Garden'), consisting of anecdotes, aphorisms, and biographies; the *Dabistan i Masahid* of Mohsin Fani, giving a sketch of Oriental sects, &c. Persian, it may be noticed, is the medium through which much of the rich Indian literature of tale and fable has passed westwards. See S. Rousseau, *Flowers of Persian Literature* (Lond. 1802); Hammer-Purgstall, *Geschichte der schönen Redekünste Persiens* (Tub. 1818); Chodzko, *Specimens of the Popular Poetry of Persia* (Lond. 1842); Sir G. Ouseley, *Notices of Persian Poets* (Lond. 1846); Zenker, *Bibliotheca Orientalis* (2 vols. Leips. 1846-59); Morley's

Catalogue of Persian MSS. (Lond. 1854); and G. B. de Meynard, *La Poesie en Perse* (Par. 1877).

Persian Powder. Various species of *Compositæ* have for a long period been recommended as insecticides, and in recent times some of the genus *Pyralium* have obtained considerable reputation. In 1846, Zacherl, a Tiflis merchant, introduced into Vienna under the name of Persian insect powder the pulverised flowers of *P. carneum* and *P. roseum*, two species growing wild, and also cultivated in the Caucasus and Persia. The preparation has proved efficacious in the destruction of insect pests, as also the flowers of *P. cinerariaefolium*, a Dalmatian plant.

Persigny, Jean Gilbert Victor, Duc de, son of a commercial speculator, was born at St. Germain-Lespinasse (Loire), 11th January 1808, joined the cavalry school at Saumur in 1826, and was appointed quartermaster of the 4th hussars in 1828. He became a revolutionist in July 1830, which lost him his military post, but joining the *Temps*, he wrote under his proper name of 'Fialin.' In 1834 he was converted to Bonapartism, and supported it in *L'Occident Française*. This led to an introduction to Louis Napoleon, with whom his career was subsequently bound up. It was P. who organised the Strasbourg plot and who encouraged the landing at Boulogne. The former effort he defended in a pamphlet, *Relation de l'Entreprise du Prince Napoléon Louis* (Lond. 1837); for the latter he was sentenced to twenty years' imprisonment. On the fall of Louis Philippe he hurried to Paris, gave energetic support to the Bonapartists, was appointed major-general of the Parisian National Guard and aide-de-camp of the President, became a member of the Assembly and ambassador to Berlin in 1849, assisted at the *coup d'état* of December 1851, and was raised to the Ministry of the Interior in 1852. In May of the same year he received the title of Comte, with 500,000 francs, on his marriage with a grand-daughter of Marshal Ney. He was sent as ambassador to England in 1855, was recalled to the Home Office in 1860, resigned in 1863, and received a dukedom. He died at Nice, January 12, 1872. P. was a consummate tactician, and a Liberal within the limits of the imperial theory.

Persimon. See DATE PLUM.

Persius Flaccus, Aulus. the successor in Roman satire of Lucilius and Horace, and the antecessor of Juvenal, was born at Volaterræ, in Etruria, 4th December 787 A.U.C., and died 24th November 815 A.U.C., at the early age of twenty-seven. P. was a Roman knight of high connections. His father, Flaccus, died when he was six years old, and his mother, Fulvia Sisenia, married a second husband by name Fusius, of senatorian rank, and within a few years became a widow. P., after receiving such education as his native town was able to afford, removed at the age of twelve to Rome, where he enjoyed the instructions in grammar of the then famous Remmius Palaemon, and in rhetoric of Virginius Flavius. He afterwards became the pupil of Cornutus, the Stoic, who made a strong impression on his tender and plastic mind. P. lived on familiar terms with the poets Lucan and Cassius Bassus, and with many others of literary celebrity; with Seneca the philosopher, also, but of the latter's talents he entertained but a lukewarm opinion. The virtuous Paetus Thrasea he revered, and by him was revered in turn. P. died of a disease of the stomach at his estate near the eighth milestone on the Appian Way. His extant works—six satires in all—were written slowly and at intervals. Altogether they number but 650 hexameter lines. His friend Cornutus corrected them, and Cassius Bassus edited them, at the author's express desire. The popularity of the satires of P. has been immense. Not only in Rome in his own day, but in mediæval times, his fame was of the highest. Scholiasts and grammarians cited him at every turn. Augustine, Lactantius, and Jerome were enamoured of him. In short, he was for long the pet heathen satirist. Latterly his reputation has waned. His youthfulness, and the unripeness of his genius, combined with his obscurity of style and language, have been against him. His nobleness and purity of soul, however, are still universally recognised. Few more virtuous men have written, certainly none with more verve and dramatic force, in the Latin tongue. The *Ediio Princeps* was published at Rome 1469, folio, along with the works of Juvenal. Many editions followed, among which may be noted those of Casaubon (Par. 1605), Passow (Leips. 1809), Weber (Leips. 1821-31), Jahn (Leips. 1843).

English, French, and German translations are numerous. The English versions by Dryden and Gifford are well known, but the translation *par excellence* is that by Conington, with commentary (Macmillan, Clari. P., 2d ed. 1877).

Person (Lat. *persona*, orig. a 'mask,' then a 'character' or 'person'), is an important word in the nomenclature of theology and metaphysics. Originally denoting the mask worn by a Roman actor, not so much to conceal his own features as to set forth the supposed likeness of the character he was representing or 'personating,' it naturally acquired even in Latin the sense it now bears in English. Its theological use has arisen in connection with the doctrine of the Trinity (q. v.), and as this use seems to violate the philosophical definition of a P., viz., a distinct, self-conscious individuality, many Christians have felt, in regard to the doctrine, a perplexity which has not quite vanished under the assurance that it is an 'incomprehensible mystery.' It may be proper to notice that P. is not a New Testament word, and that nothing whatever is said in Scripture about a Godhead consisting of 'Three Persons.'

Personal, in English law. See REAL.

Personification (Gr. *prosopopeia*) is a figure of speech which consists in attributing life and mind to inanimate objects, or even to mere abstract conceptions. Its use marks a high degree of passion or enthusiasm; it is therefore a favourite form of expression with orators and poets. Milton's vision of 'a noble and puissant nation' in the *Areopagitica* is an eloquent instance of P. One still more imaginative occurs in the passage (*Paradise Lost*, Bk. ix., ll. 782-84) where Eve plucks the forbidden fruit:—

'Earth felt the wound; and Nature from her seat,
Sighing through all her works, gave signs of woe,
That all was lost.'

Personnel. By the P. of an army is meant the officers, non-commissioned officers, rank and file, and all other persons composing it. The term *materiel* is applied to the ordnance, ammunition, stores of all kinds, and everything necessary for its equipment and maintenance, &c.

Perspective is the representation upon a surface of objects exactly as they appear to the eye. It is really a branch of practical geometry, and depends upon the mathematical principles of projections. (See PROJECTION.) Only with what is called linear P., i.e., the accurate delineation of the principal lines of the picture, have we here to deal. The shading and colouring, so as to produce the desired illusion as to distance, magnitude, &c., though included in Art under the general name of P., are not considered, since they really lie beyond the limits of application of strict mathematics. It is not intended to define more than a few of the more important technical terms which are in use; for such, reference must be made to the numerous treatises and text-books upon the subject. The first principles, upon which the whole depends, and the fundamental conceptions which underlie these, shall alone be briefly indicated. If lines be drawn from every visible point of the surface of a body to the point of vision, a solid cone of rays, taking *cone* in its widest sense, will be formed, having its vertex at the point of vision. The section of this cone, by any given surface, is the P. representation of the object upon that surface. Ordinarily the surface chosen for representation is a vertical plane, which is technically named the *picture plane*. Imagine this picture plane to be transparent, and interposed between the object viewed and the eye of the observer, or point of vision. The cone of rays, drawn from the point of vision, and touching the object, intersects the picture plane in the boundary of a closed region, which is the true P. outline of the object. A little consideration shows that, keeping the point of vision and the picture plane fixed, the size of the P. representation of any object diminishes as the distance of the object is increased, and *vice versa*. Hence parallel lines, which do not lie in a plane parallel to the picture plane, appear convergent in P. Further, all mutually parallel lines which are perpendicular to the picture plane, converge in P. to the *centre of vision*, which is the point on the picture plane directly opposite the spectator's eye, since it is through this point that the perpendicular from the point of vision to the picture plane is drawn. In constructive P. this centre of vision is all important, and the horizontal line drawn through it upon the picture represents the horizon of the spectator. Any plane passing through the

spectator's eye, or any part of this plane, appears on the picture plane simply as a line. The *P.* outline of a sphere will in general be an ellipse, an oblique section, namely, of a right cone by a plane. When, however, the centre of the sphere lies on the line drawn from the eye through the centre of vision, the projection of the sphere upon the picture plane is a circle—the right cone is cut by a plane perpendicular to its axis. Similarly a circle drawn upon any given plane appears in general an oval resembling an ellipse; and the inscribed square becomes a quadrilateral whose sides appear to converge. The point towards which parallel lines appear in *P.* to converge is called the vanishing point; and when this point is known, together with the distance between the lines and the plane in which they lie, the lines can be drawn. The vanishing point of lines which are parallel to the horizontal plane lies upon the horizontal line; and all lines which have the same vanishing point make the same angle with the picture plane. The application of these principles to the drawing in *P.* of an object, whose distance, dimensions, and position are given, forms what may be termed the *art* of *P.* A knowledge of its methods is necessary to the architect and draughtsman, who should also be fully acquainted with the theory. In landscape painting the *P.* is not so evident; and the artistic effect depends for the most part upon the shading and colouring, which, combined with the varying magnitudes of the objects composing the subject, give the required illusion to the eye. See DRAWING and PAINTING.

Perspiration. See SWEAT.

Pertápghur (*Pratapgarh*, 'fort of Pratap'), (1) The capital of the native state of the same name in the N.E. of Rajputana, India, 33 miles S. of Neemuch, and 206 N. of Baroda. The state of *P.* has an area of 1460 sq. miles; pop. 150,000, the majority of whom belong to aboriginal tribes; the gross revenue is £60,000, of which £20,000 is enjoyed by feudatories, and £7200 paid as tribute through the British Government to Holkar, the Mahratta Rajah of Indore. The crops are maize and millet. The title of the chief is Maharawal.—(2) *Pratapgarh*, the chief town of the district of the same name in Oulh, British India, 2 miles from the right bank of the Sae river, 32 miles from Allahabad, and 90 S.E. of Lucknow; pop. (1869) 6240. It is an old town with a ruinous rampart and fort of mud. The district of *P.*, which lies in the S. corner of the province, has an area of 1458 sq. miles; pop. (1869) 784,156. The crops are rice, wheat, Indian-corn, barley, sugar-cane, &c.; saltpetre is also produced.

Perth, a royal burgh of Scotland, and capital of the county of the same name, on the right bank of the Tay, 45 miles N.N.W. of Edinburgh by the Fife railway, 69 by the Stirling line, and 22 W.S.W. of Dundee. The 'Fair City,' no less remarkable for its wealth of traditions than for its beauty of situation, is in great part handsomely built of freestone, and lies in the wide fertile stretch of Stathmore, with the Ochil Hills in the S., the Sidlaw Hills in the N.E., and the splendid northerly background of the Grampians. From the Moncrieff and Kinnoull Hills in the vicinity may be obtained a view which Pennant calls 'the glory of Scotland,' embracing the rich Carse of Gowrie, the noble Firth of Tay, with Dundee on its margin, and the beautiful valley of Strathearn, girt by the hills of Menteith. The Tay, here widening to its estuary, is spanned by a stone bridge of ten arches 880 feet long, and by a handsome stone and iron railway viaduct with a public footpath. The suburb of Bridgend lies on the W. bank of the river. On either side of *P.*, and extending along the river, are the beautiful meadows called the N. and S. Inches, about a mile and a half each in circumference. They are occasionally flooded by the rising of the Tay, and so low is the level of the city itself that a rise of about 12 feet above ordinary high-water mark is sufficient to flood the principal streets. The old Kirk of St. John, now comprising the churches of E., Middle, and W. parishes, is a massive edifice in Pointed style, with a square tower and spire 155 feet high. Here Knox preached the celebrated sermon that was followed by the demolition of the monasteries. Other notable structures are the County Buildings, erected in 1819 on the site of old Gowrie House; the Penitentiary, the largest in Scotland, with accommodation for 535 convicts, besides criminal lunatics and 52 juveniles; the spacious barracks, erected in 1793; the Marshall Institution (1823), containing a public library and

the collection (probably the finest provincial one in Scotland) of the Literary and Antiquarian Society, founded 1784; James VI.'s hospital, rebuilt in 1750; an infirmary, dispensary, and other charitable institutions; the schools; the auction marts for the sale of cattle (by far the largest and most elegant in Scotland); and the handsome central railway station. Before the Reformation *P.* contained a number of religious houses, of which no remains are now traceable. In 1878 there were twenty-six places of worship. *P.* has manufactures of cotton fabrics, winseys, gingham, and shawls, and there are flax-mills, bleachfields, tanneries, breweries, distilleries, iron foundries, &c. The exports are chiefly manufactured goods, salmon, and agricultural produce. In 1876 there entered the port 121 vessels of 9403, and cleared 126 of 9813 tons. In 1876 the imports amounted to £19,340, and the customs to £21,414. In 1877 there belonged to the port 32 vessels of 2637 tons. The salmon fisheries are of importance. Races take place in October on the N. Inch, and seven fairs are held annually. *P.* returns one member to Parliament, and publishes three newspapers, one once a week, a second twice a week, and a third thrice a week. In 1877-78 the annual value of real property (inclusive of railways) was £112,639, and the corporation revenue was £6700. Pop. (1871) 25,585; (1876) 26,535. A city of great antiquity, tradition even ascribing its foundation to the Romans, *P.* first becomes important in the 12th c., and was a residence of the Scottish kings till the ruthless murder of James I. by the wild clansmen of Sir Robert Graham (1437) showed it 'on startling evidence to be too near the Highlands for safety' (Burton). The kings had no palace here, but the court found ample reception in the Cistercian Convent. Among the places of interest in the vicinity are Scone Palace, a modern castellated building, the remains of Scone Abbey, and Dupplin Castle, with its famous classical library. *P.* was the seat of a General Assembly of the Church of Scotland in 1618, which met at the command of King James, and drew up, under a certain degree of compulsion, the notable 'Five Articles' enjoining kneeling at the Lord's Supper, the observance of Christmas, Good Friday, Easter, Pentecost, and Confirmation, and sanctioning the private administration of baptism and the Lord's Supper. These articles were condemned and repudiated by the famous Glasgow Assembly of 1638.

Perth, the capital of W. Australia, is picturesquely situated on the Swan River, 12 miles from its mouth, in 31° 20' S. lat., 115° 46' E. long. It consists principally of one main street nearly two miles long and lined with trees, and contains some good public buildings. The chief of these are the City Hall (built entirely by convict labour), the basement of which is used as a market, and the Protestant and Roman Catholic cathedrals. Pop. (1870) 5007, including the military and 400 convicts.

Perthes, Friedrich Christoph, a patriotic German publisher, was born at Rudolstadt, April 21, 1772, and apprenticed to a bookseller at Leipsic in 1787. After six years of business training and literary study, he passed to Hoffmann's establishment at Hamburg, where eventually (1796) he entered into the trade on his own account, and formed the friendship of many of the most famous men in Germany. In 1810 he started the *National Museum*, which achieved a wonderful popularity through the contributions of such men as Jean Paul Richter, Schlegel, and Arndt. *P.* took an active part in freeing Hamburg and N. Germany from the French in 1813-14, and in 1822 removed to Gotha, where he established a publishing business, which soon became famous for the issue of historical and theological works. He died 18th May 1843.—**Clemens Theodor P.**, son of the preceding, born at Hamburg, 2d March 1809, became Professor of Law at Bonn, was the friend and teacher of many Germans of the highest rank and fame, and wrote *Das Deutsche Staatsleben vor der Revolution* (1845), and the interesting *Friedrich P.'s Leben* (6th and centenary ed. 1872). He died 25th November 1867.—**Johann Georg Justus P.**, uncle of Friedrich, probably born at Rudolstadt, founded at Gotha in 1785 the publishing firm still celebrated beyond Germany by the name of 'Justus P.', and died 2d May 1816.—**Bernhard Wilhelm P.**, grandson of the latter (born 1821, died 1857), was the founder of the *Geographisches Institut* (1854), which has become world-renowned through the publication, in its *Mittheilungen* (edited by Dr. Petermann), of maps by Stieler, Berghaus, Spruner, Sydow, &c., and of contributions by travellers

in every part of the earth. The *Almanach de Gotha* (q. v.), also by the firm of Justus P., is by far the best work of the kind published in any country.

Perthshire, the central county of Scotland, is bounded N. by Inverness and Aberdeen, S. by Stirling and Clackmannan, W. by Argyle and Dumbarton, and E. by Forfar, Fife, and Kinross. Area, 2601 sq. miles, or 1,664,690 acres; pop. (1871) 127,768. It is 70 miles long from E. to W., and 66 broad from N. to S., and lies on the border of the Highlands, comprising every variety of Scottish soil, climate, and scenery. Its natural boundary along the N. is the main range of the Grampians (q. v.), and along the W. the Southern Grampians, and the principal heights within the county are Ben Lawers (3935 feet), Ben More (3818), Ben Voirlich (3160), Schehallian (3564), Ben Scarsoch (3390), Ben Ledi (2863), and Ben Venus (2388). The Ochils (q. v.) traverse the S.E. of the county, separating the basins of the Forth and Tay, while the Sidlaw Hills, which attain a height of 1500 in Birnam Hill, separate the Carse of Gowrie from the broad plain of Strathmore. The detached hill of Dunsinane, an offset of this latter range, is famed in Scottish tradition as the site of Macbeth's castle. The chief river of P. is the Tay (q. v.), a noble stream, which, with the exception of part of its firth, is wholly within the county, and flows with a great northerly bend from W. to E., expanding in Loch Tay (16 miles), and receiving the Lyon, Tummel, Garry, Bruar, Isla, Almond, Earn, &c. The 'P. Highlands' comprise almost the whole N.-western half of the county, and this region is intersected by a network of valleys and glens, of which the most celebrated are Strath Tay or Strathmore, Strathearn, Glens Almain (the 'Sma Glen'), Shee, Ericht, Fernal, Bruar and Tilt. The principal passes are Aberfoyle, Leny, Comrie, and Killiecrankie. Besides Loch Tay, there are numerous sheets of water, as Lochs Earn, Katrine, Achray, Venacher, Lubnaig, Voil, Ranuoch, Lydoch, Tummel, and Ericht. The river Forth forms part of the southern boundary, and receives from P. the Allan and Teith. In the W. of P. is the extensive moor of Rannoch, and in the S.W. are the beautiful Braes of Balquidder. Old Red Sandstone prevails in the Lowlands, and in the Highlands mica schist, with occasional beds of quartz, sandstone, greywacke, and patches of granite. The chief minerals worked are roofing slates, coal, ironstone, blue marble, and limestone. In 1876 there were 106,006 acres under corn crops, 50,393 under green crops, 99,100 in clover, sanfoin, and grasses in rotation, and 79,343 in permanent pasture, exclusive of mountain and heath. In the same year P. had 13,764 horses, 80,024 cattle, 659,210 sheep, and 9597 pigs. The chief crops are oats, barley, wheat, turnips and potatoes. In 1877-78 the valued rental was £871,801, exclusive of £151,474 for railways and waterworks. The principal towns are Perth, Couper-Angus, Auchterarder, Crieff, Dunkeld, Blairgowrie, and Callander. P. returns one member to Parliament. Many of the finest mansions in Scotland belong to this county, but of these Scone Palace alone is famed for its historical memorials. P. lay beyond the Roman wall; and Mons Grampius or Graupius (see GRAMPIANS), between Dunblane and Crieff, was the scene of the final triumph of Agricola over the Caledonians, A.D. 84. Besides Roman roads and camps, P. has numerous interesting antiquities, including the cathedrals of Dunblane and Dunkeld, and the Abbey of Culross. P. is traversed by the 'Highland Railway,' which crosses the Grampians, and forms the direct route to Inverness and the Northern Highlands.

Perturbations, in astronomy, are the inequalities which exist in lunar and planetary motions. These inequalities are so inconsiderable that they require for their detection more delicate and longer continued observations than suffice for establishing Kepler's laws. From these laws, Newton was led to the universal law of gravitation, that every particle in the universe attracts every other particle with a force which acts in the straight line joining them, and is directly proportional to the product of their masses, and inversely proportional to the square of the distance separating them. When such a system, then, as is formed by the sun, earth, and moon is considered, it is evident that other forces exist than that which acts between the sun and earth. Consequently we cannot reasonably expect that the earth should move in a perfect ellipse round the sun, or the moon similarly round the earth. Both theory and observation, indeed, indicate the existence of irregularities or inequalities, and these

are technically called P. If only two bodies existed in the universe, and both of uniform spherical form, their motions round their common centre of mass would be easily determinable by mathematical analysis. Introduce a third body, and the difficulties are greatly increased, and the problem is incapable of general solution. For particular cases, however, the solution may be obtained to any degree of approximation by the use of infinite and rapidly converging series. Though the moon is commonly said to describe an ellipse, of which the earth occupies the focus, this is only true to a first and very rough approximation. The moon's mass is quite comparable to that of the earth, and accordingly the centre of the earth is far from coincident with the system's centre of mass. Still, however, the moon's orbit would be elliptical were it not for the P. caused by the attraction of other bodies, and especially of the sun. In discussing the lunar theory, the sun is supposed to revolve round the centre of mass of the earth and moon in an elliptic orbit during one year—though in reality it is the earth and moon which revolve round the sun. The plane of this (apparent) orbit is of course the ecliptic, to which the plane of the moon's orbit is always inclined. The whole perturbing force due to the sun is found by compounding the attraction of the sun upon the moon at any instant with the simultaneous attraction of the sun upon the earth taken in the opposite direction. In dealing analytically with this resultant, it is advisable to break it up into three rectangular components, and study the P. due to each separately. This we can do because of the smallness of the perturbing force compared to the force which really determines the moon's orbit. The most convenient directions in which to resolve the sun's perturbing force are (1) along the projection upon the ecliptic of the moon's radius vector; (2) perpendicular to this direction in the plane of the ecliptic; and (3) perpendicular to the plane of the ecliptic. The more important inequalities to which those forces give rise are noticed under Lunar Theory (q. v.). The investigation of the planetary theory, though depending upon the same principles as that of the lunar theory, is conducted very differently. The difference in the conditions of the problems necessitates a great diversity in treatment. Here we have to consider the inequalities of one given planet due to the attractions of all the rest. The great mass of the sun as compared with the mass of any planet, or indeed with the total mass of them all, greatly simplifies the problem, inasmuch as the disturbing forces must be insignificant compared to the central force which determines the orbit. In the case of the moon, the sun's great mass makes up for its great distance, so that the changes in the elements of the moon's orbit are rapid compared to the changes in the elements of a planet's orbit, which can only be detected by their cumulative effect through the lapse of time. Hence in discussing the planetary theory, the orbit is assumed to be elliptical, but the ellipse is taken as slowly changing. This is known as the method of the *variation of parameters*. Its principle is simply that the elements which determine the ellipse are subject to secular variation; and hence the orbit for a given instant is determined by simply substituting in the equations the particular values which the elements have at the instant in question. The whole bearings of the subject of perturbing forces were clearly seen by Newton, who left the lunar theory almost as complete as it now is. The elaborate researches of Lagrange, Laplace, Clairaut, Euler, and other mathematical astronomers, have been ably supplemented by the inquiries of savants of our own time, such as Airy, Hansen, Leverrier, Adams, Newcomb, and Thomson. See Airy's *Mathematical Tracts*, and for a more popular account, Herschel's *Outlines of Astronomy*.

Pertussis. See HOOPING-COUGH.

Peru, a republic in the N.W. of S. America, bounded on the W. by the Pacific, on the N. by Ecuador, on the E. by Brazil, and on the E. and S. by Bolivia. Its inland frontier-line has recently been rectified by arrangement with Brazil, and the limits of the country as rectified are in lat. 3°—32° S., and in long. 68° 12'—81° 32' W. Its area, according to the *Almanach de Gotha*, 1878, is 617,593 sq. miles; and its pop., according to the census of 1876, is 3,703,070. The greatest width of P. is in the extreme N., between Cape Blanco on the W. and San Antonio on the E., where the country measures over 850 miles across; its narrowest measurement is in the S., where, at Arica, it contracts to about 50 miles. The coast line, extending over 21° of lat. (1323 miles), slopes

S.S.W.), and is almost unbroken by great indentations. Still there are a number of open bays upon which harbours, usually of the rudest and simplest description, have been planted. The chief of these are Paita, Trujillo, El Callao (q. v.), the port of the capital Lima, and Iquique. The islands, inconsiderable in number and in size, are of great value for their guano deposits. Of these, Lobos de Tierra (lat. 6° 27' S., long. 81° 41' W.), the largest guano island in the world—7 miles long—Lobos de Afuera (lat. 6° 57' S., long. 81° 41' W.), and the Chincha Islands (q. v.), are among the chief. P. is divided into 21 departments and 3 littoral provinces.

Physical Aspect.—The scenery of P. is probably unique for imposing grandeur and variety, a distinction due to the singular contour of its surface. Within its limits are to be found a number of the loftiest mountain peaks, the most stupendous precipices and ravines, the most arid and desolate plateaux, and the most fruitful tropical valleys to be met with in the world. Its mountains clad with snow-mantles, only the fringes of which are melted in the summer heats, send down westward-flowing torrents through the tremendous gorges of the Cordillera to the Pacific, and eastward-flowing rivers through the softer valleys of the twin ranges of the Andes—rivers swift but gentle of current, which, forming the head waters of the Amazon, reach the sea on the opposite or Atlantic side of the continent. Lake Titicaca lies at a level almost as lofty as Mont Blanc, and the Oroya Railway attains the unparalleled elevation of 15,545 feet. The Andes (q. v.) here bifurcate into the E. and W. Cordilleras, the western range being the higher, and that in which alone occur volcanoes. The W. Cordillera is of granite and metamorphic rocks, the eastern or inland one of limestone in a state of disintegration, forming fantastic peaks. Between the E. Cordillera and the Pacific there intervenes a low-lying strip of desert land—a waste of sand and rock, about 40 miles in width, the domain of silence and of death. The sand of this wind-swept desert is hard, smooth, monotonously level, and strewn with heaps of bones. This maritime strip, the *Costa*, is intersected at intervals by exceedingly fertile and beautiful valleys, which mark the courses of the streams descending from the snow-clad Cordillera to the Pacific. Before the Spanish *conquistadores* arrived in the country, the waters of these streams were carefully preserved by aqueducts, and distributed by wonderful contrivances for the purposes of agriculture, but even in that age the watered valleys, though liberally peopled, were isolated by many leagues of deadly desert. This circumstance helps to explain the remarkable fact that in penetrating into the country Pizarro and his cavaliers met with no organised or effective resistance. From the coast rises abruptly the giant bulk of the Cordillera, with its immense volcanoes, its snowy peaks, and its minor hills, which would be vast mountains in any other country save perhaps in Northern India. Between its summits there are few gorges, but instead of the appalling chasms and ravines of the more eastern range, its shoulders extend afar in broad undulating plains called *punas*, which vary from 14,000 to 18,000 feet above the sea, and are frigid, sterile, dead, save for the condor that is loitering above and the vicuña, the one sole denizen below. These *punas* taken together form the region which is known as the *Despoblado* ('The Unpeopled'). 'Here,' writes Squier, 'no trace of human habitation is discovered. The traveller is happy to obtain the protection of a cave or the shelter of a rock at night, and by day hurries as fast as his starving mule, suffering from the rarefaction of the atmosphere, will enable him, across the dreary waste.' The *Despoblado* is on an average 150 miles broad, and though it varies in elevation, it is throughout a desolate and repulsive region. Eastward from it and extending between the Cordilleras is a vast valley about 11,000 feet above the level of the sea. Compared with the mighty ranges on either side, this *Platón*, as it is called, seems flat, yet even it has its mountains and valleys, rivers and lakes, and seems to be a section cut from the ordinary surface of the earth, heaved up to the elevation of Alpine summits, and supported there on each side by the massive shoulders of the Andes. In some quarters the two great mountain-ranges are separated by from 100 to 200 miles of *Despoblado* and *Platón*; in others, nearing each other, they finally coalesce and form a 'knot,' in which the geographer fails to determine to which range the individual mountains belong. There are two famous 'knots' in P. The first at the Pass of La Raya (lat. 14° 30' S., long. 70° 50' W.), where the Rio

Vilcanota, said to be the true source of the Amazon, has its origin in a dark mountain lake and flows northward, and where also springs the Rio Pacura, which, flowing southward, falls into Lake Titicaca. The Raya Pass, therefore, is on the watershed between the northward and the southward flowing streams of the country. The other famous 'knot' is in lat. 10° 15' S., long. 76° 10' W., near the famous mines of Cerro de Pasco. The name *Sierra* is applied to the whole of the central mountain-system of the country, from its northern to its southern boundary, although between the mountain ranges there are subordinate regions, as the *Despoblado* and the *Platón*, which have distinctive appellations. Of the latter sub-region the extensive and peculiar basin of Lake Titicaca (q. v.) in the S. forms a part. The lake, a magnificent body of fresh water, receives several considerable streams, and discharges its surplus waters by the Desaguadero River into the Bolivian Lake Aulagas, of which little is yet known save that it has no ascertained outlet to the sea. The soil of the islands and the shores of Lake Titicaca is poor, and the climate cold. Here barley seldom ripens, and the *buscachá*, llama, and vicuña are the only indigenous animals fit for food. Another noticeable feature of this singular country are its mountain-ringed valleys named *bolsones* (Span. *bolsón*, 'a pocket'). These *bolsones* vary in altitude, and, necessarily, in climate and productions. Surrounded by mountain-ranges or by the high *punas*, these 'pockets' are naturally isolated—the routes of communication between them being by the dizziest, narrowest mountain tracks, or across river ravines by means of narrow, flail, wind-swung bridges, formed of cables of plaited withes. The principal, or at least the most noteworthy, *bolsón* is that of Cuzco, and the most remarkable with the bridge is that on the route from Cuzco across the Apurimac (*Apu-rimac*, 'the great speaker'), that speaks with the voice of thunder. The eastward border-land of the Peruvian territory is called the *Montaña*, and comprises more than two-thirds of the whole area of the country. It consists in great part of wide plains, traversed by the headwaters of the Amazon, and covered with gigantic forests which extend for about 5500 feet up the mountain-sides.

Climate, Soil, and Productions.—P., lying in the region of perpetual S.E. trade-winds, is swept by these winds after they have all but exhausted their moisture on the wooded plains of Brazil. The last particles are intercepted in the form of snow by the lofty Cordilleras, and the wind whistles over the *Costa* cold and dry. In some parts of this region no rain has fallen within human memory, but the absence of rain is partly compensated for by the *arua* or fog. The central *Platón* is noted for the mildness and comparative humidity of its climate. In the higher uplands the climate is often inclement, and the plains of Titicaca and Pasco are especially notorious for terrific tempests and thunderstorms. P. is pre-eminent over all S. American countries for the frequency and violence of its earthquakes. Of the soil of P. little need be said, as there is not much of it. Prescott, following, perhaps too faithfully, the gossip of Garcilasso de la Vega, has described the system of agriculture of ancient P. as perfect, and its results as bounteous. For long the industry of P. has been turned from agriculture to mining and the trade in guano. But there are now considerable valleys and tracts producing maize, rice, tobacco, coffee, sugar, cotton, &c. Much of P. is admirably suited for the cultivation of cotton, and the cotton already produced is of excellent quality. P. imports grain and potatoes from Ecuador and Chili. The productions of P., recognised as mercantile, are guano, nitrate of soda, cinchona bark, silver, sugar, cotton, and rice. The population is almost confined to the towns that fringe the coast, and are scattered over the *Platón* and *Sierra*. Perhaps the most populous part of P. is the valley of the Apurimac.

Internal Communication.—The streams flowing westward from the Cordillera are, for commercial purposes, of little value. The rivers flowing eastward from the *Sierra*, the chief of which is the Amazon (here called the Marañón), with its affluents the Ucayali, Apurimac, Vilcanama, Huallaga, &c., are of greater volume, and offer facilities for navigation into the very heart of the country. At present the chief place on the P. Amazon is Yquitos, with an arsenal and a port for Government steamers plying on the river. Up the Ucayali, and its tributary the Pachitea, steamers have advanced to the very base of the Andes, and to a point said to be only 220 miles from Callao. The roads of P., which are said to have been so perfect under

the older civilisation, have virtually ceased to exist, or are represented, at least in the uplands, by broken, dangerous rail-paths. The railways of P. are among the wonders of the New World. The country owns, for its area, a greater mileage of railway than any other of the American states. This fact, however, is, in the present condition of affairs, no matter to boast of, as at present P. has little goods and less passenger traffic. Mr A. J. Duffield states that 'The Government railways cost enormous sums and bring in nothing; and it may safely be said that they will never figure, honestly, in the national accounts, except as items of expenditure.' The Government has contracted loans for these railways to the amount of \$150,000,000. On the subject of Government railways the latest ascertained facts are, according to Mr. Graham, British Consul at Islay (1875), that the works on the railroad which were to have connected Cuzco with Arequipa and the coast have been stopped, owing to the inability of the Government to pay the contractors, and the plant which had been accumulated has been removed, and shipped away to other places. Writing in 1876, Acting-Consul Robilliard states that the railway works to Cuzco have not been touched since 1875, but if a proposal now before Congress be accepted, it is probable that the line to Cuzco will be continued, at any rate half way. Upon other great national undertakings, and chiefly upon waterworks, the Government of P. have expended about £20,000,000. At the close of 1876 there were in operation 1281 miles of railway belonging to the state, 496 miles belonging to private persons, and 253 miles belonging partly to the state and partly to private owners. The entire railway system in working order or in course of construction in 1876 comprised twenty-two lines of 2030 miles in length, and representing a cost of £35,994,920. The amount of receipts from these is unknown, but only the lines belonging to private companies have yet proved remunerative.

Industries and Commerce.—The chief commercial resources of P. are its great deposits of guano and nitrate of soda (see GUANO and NITRE). Mr. Duffield, perhaps the best informed inquirer on the subject, states, that the known unexploited beds of guano amount in all to about 7,500,000 tons, selling at about £16 per ton. Further, he states that he found 'certain unmistakable indications of even larger deposits which may lie buried a hundred feet below the sand on the slopes of the southern shore,' and he draws attention to the circumstance that a month after his departure from Lima a meeting was held at the Treasurer's office—many heads of departments being present—for the purpose of receiving a communication from two Englishmen, setting forth the discovery of fresh guano deposits on the coast, in the (southern) province of Tarpaca. From all that could be gathered, the new deposits may be fairly estimated as containing 3,000,000 tons of guano. In 1876, 156,864 tons of guano, of the value of £1,966,068, were exported, to Great Britain. The immense deposits of nitrate of soda occur in a wild, desolate pampa in the province of Tarpaca, 150 sq. miles in area, and which on the safest calculation will yield 70,000,000 tons of nitrate. In 1877 a company was formed for the purpose of working these deposits. The uses to which this substance is applied are multiplying yearly. At present it is highly valued as a fertiliser, and its commercial value is £12 to £12.10s per ton. The amount of nitrate exported in 1876 to Great Britain was 3,064,707 tons, valued at £1,761,450. The gold and silver mines of P. are not now productive, and mining can scarcely be regarded among the profitable occupations of the inhabitants. Potosí, once as celebrated for its silver as Golconda for its diamonds, is now poor, and, like Golconda, shorn of its ancient renown. The chief silver mines are now those of Cerro de Pasco (13,800 feet above sea level, and difficult to work for this and other reasons) and those on the shores of Lake Titicaca. The chief copper mines are those on the Chimboite Huariz line of railway. Both copper and tin of great purity are worked between the great mountain chains in the south, but gold mining is now almost too inconsiderable to require notice. A bed of coal of great but undefined extent was discovered in 1877, near Oluzco, in the department of Libertad, and it is anticipated that this important discovery will immediately lead to a vast extension of the mining industry of the country. In 1876 the total exports to Great Britain amounted to £5,630,670. Among the exports were £503,224 worth of alpaca wool and £912,799 of unrefined sugar, while the imports comprised £324,350 worth of cotton goods, £130,016 of woollens, and £59,757 of coal.

The other imports are preserved provisions, silk goods, wines, liquors, and drugs. Among the reasons given for the backward state of P. are (1) the accessibility of the guano and nitrate deposits, which has withdrawn labour from other pursuits, (2) the liberation of the negro-slaves and the abolition of the poll-tax formerly paid by the Indians, and (3) the employment of Chinese coolies, of whom there are 60,000 in the country.

Religion and Morality.—The religion is Roman Catholic, and no liberty is allowed for the public exercise of any other form of worship. Peruvian morality is not high. The habits of the upper classes are luxurious, frivolous, and idle; the national temperament is passionate; and Lima, the metropolis, is one of the gayest and grossest capitals in the world. Bull-baiting is universally popular, and not only are the animal's horns often loaded with fireworks, but as an occasional novelty a condor is fastened on his back to lacerate the flesh with its terrible beak. During the year 1875, 1642 children were baptised at Callao, of which 654 were legitimate and 988 were illegitimate. The native Indians, about 350,000 in number, are wholly uncared for by the Government in every sense—religious, educational, and political. The 'priests' of the various provincial districts are habitually drunken, extortionate, and ignorant.

Government, Army and Navy, &c.—P. became independent of Spain on the 28th July 1821. The constitution, as at present (1876) existing, was adopted August 31, 1867, and is modelled on that of the United States. The legislative power is vested in a Senate of 44 members and a House of Representatives nominated by the electoral colleges of provinces and parishes, one member for every 20,000 inhabitants. The President of the Republic is assisted in the administration by a cabinet of five ministers. Receipts for the year 1875-76, £10,220,000; expenditure, £12,500,000. There is an ever increasing foreign debt, which in January 1876 amounted to £49,010,000, besides a floating debt of unknown amount. At the beginning of 1877, such was the depreciation of Peruvian credit, that Lima bank-notes were at a discount of 50 per cent, and the sole, the nominal value of which is about 4s, has fallen in exchange in England to 2s and 2s 6d. The army in 1877 consisted of 13,200 troops, and the navy of 6 ironclads with 38 guns, and 6 other steamers with 56 guns. The mercantile marine, in 1876, consisted of 147 vessels of 49,860 tons, and of which 8 were steamers. No official statistics of the general commerce of the country are issued.

Antiquities and Culture.—If the antiquity of a nation be no higher than that of its earliest written records, the history of P. will be found to reach back only to the beginning of the 16th c., when the Spaniards under Pizarro invaded and conquered the country, cruelly sifting its treasures, and carelessly despoiling, for the first time, its appearance, resources, &c., and made imperfect attempts to reduce its contradictory traditions to form. But though the earliest descriptions of P. are little more than three and a half centuries old, the Peruvian nation is of the highest antiquity. On landing on the shores of P., the Spaniards found not a savage or primitive race, but an empire complete in its organisation, possessing the accumulated wealth of centuries, practising a social and industrial system which the shrewdest of our philosophical economists could scarcely have improved, and boasting, besides their own remarkable palaces and temples, a series of wonderful architectural remains, the antiquity of which went beyond the traditions even of the Incas themselves. From the earth houses of the ancient Bitons to St. Paul's, the distance in time and in progressive effort is perhaps not greater than from the stone huts of the early dwellers in the Sierra to the fortress and temple of Tiahuanaco, on the S. of Lake Titicaca, whose gigantic and mysterious ruins were prehistoric even to the Incas, and were regarded by them with superstitious dread. And not more remarkable than the great antiquity of these ruins is the wonderful technical skill with which the hard stones composing them have been cut, and their geometrical ornaments and carved figures been designed and executed. Mr. Squier, who has examined the architectural works of Europe as well as of N. and S. America, makes the following remark respecting these immense carved blocks—'I may say, once for all, carefully weighing my words, that in no part of the world have I seen stones cut with such mathematical precision and admirable skill as in P., and in no part of P. are there any to surpass those which are scattered over the plain of Tiahuanaco.' How many centuries must have elapsed before Indian tribes could have arrived at such a degree of mechanical and artistic accom-

ishment it is impossible to tell and vain to guess; and this all the more from the circumstance that the ancient buildings have been more or less destroyed while being ransacked by treasure-seekers, from the time of Pizarro to the present day. The palaces of the Chimu, near Trujillo, are by far the most important archaeological remains on the P. coast, and represent an older civilisation entirely distinct from that of the Incas. The remains of Tiahuanaco are believed to be as elaborate and admirable as those of Assyria, of Egypt, Greece, or Rome; and the theory has been advanced that these buildings of nameless age must have been erected by an emigrant tribe, who brought with them a civilisation from afar. It is unfavourable for this theory, and, at the same time, a most interesting and suggestive fact in itself, that P. contains many specimens of stone circles, the exact counterparts of Stonehenge and Avebury in England, Carnac in Brittany, and the sun-circles of Scandinavia and Tartary; and that from these original and unique architectural efforts, common alike in Europe, Asia, and America, the constructive genius of the early Peruvian tribes may have developed the colossal structures of Tiahuanaco, which in their turn served the Incas as the models on which their own palaces—as that of Cuzco (q. v.)—were built. The Inca architecture is of the style known as Cyclopean—that is, the walls, &c., are built of huge, irregular blocks of stone, so carefully cut however, so admirably jointed, that even to this day the point of a knife cannot be inserted between them. The ruins on the sacred islands of Titicaca and Coati belong to the most powerful time of the Incas, and include the favourite palaces and most sacred temple. Here not only do the buildings evince the greatest care, but every effort seems to have been made to render the places delightful by the construction of terraces, gardens, and baths. The *pila* (fountain) of the Incas, supplied with water through subterranean passages from sources now unknown, never diminishes in volume, and its stream is skilfully conducted from terrace to terrace till it reaches the lake. In Titicaca and Coati there is the same beautiful, complicated series of terraces, falling off in harmonious gradations from the court or esplanade of the ruined edifice to the lake. The Peruvian aqueducts were on the grandest scale, and of the most perfect construction. They conveyed water from the mountains to the towns and to the arid sea-coast, which in the great days of the empire blossomed like the rose, and was inhabited by a numerous and thriving population. Many of these aqueducts are still in use, and in not a few of the older but still inhabited buildings the aqueduct provides a constant supply of water, the source of which is wholly unknown to those who make use of it. Agriculture was pursued with a care and success unknown in any other country except China. The scanty soil on the hillsides was laid out in terraces buttressed with facing walls of stone; and such was the anxiety of the Peruvians to utilise every yard of available ground, that they refrained from burying their dead in the usual fashion, but built them up in *chulpas* or burial towers, or hid them away in caves and niches cut in the rock, so that the dwellings of the dead might not trench on the cornfields of the living. The coast tribes worshipped Viracocha, the god of the sea, from which they drew great part of their subsistence, while the tribes that inhabited the *bolsones* and the chilly *punas* bowed down before *Inti* the sun, the giver of light and heat, the bringer of food and comfort. A pure Theism, however, is believed to have been the fundamental principle of the religion of several, if not many, of the indigenous tribes. Finally, from what we know of them, the Peruvians at the period of the Spanish invasion were pious, loyal, industrious, prosperous, and happy.

The Peruvians had no alphabet, and the annals of successive reigns were transmitted orally by the *amautes* or 'wise men' in the schools of Quito. The only substantive memoranda of national transactions were the knotted cords, called *quippos*, in which the character of the events was indicated by the colour of the cords, the number and distance of the knots, &c. *Quippu*-reading, however, has long been a lost art; and we must therefore have recourse to the pages of the Spanish chroniclers. From this source we learn that, before the arrival of the Spaniards, the civilisation of P. had found expression in a literature of singular maturity and elegance. A genuine specimen of this literature is the *Alonso*, a graceful drama, translated into English by Clements R. Markham, and done afresh into German by Herr Flammberg, a Quichua scholar (Vien, 1877).

History.—The chroniclers are contradictory and confusing with

regard to the number of sovereigns of the Inca dynasty prior to the Spanish invasion. Garcilasso states that the Inca dynasty arose in the 11th c., and that there were fourteen successive sovereigns of the imperial race. He refers to the Inca race proper. Montesinos states that there were more than one hundred and one Peruvian monarchs, and that the royal race sprang into existence five hundred years after the deluge. This writer is evidently going back upon the earliest traditions referring to the first princes that ruled in this region long before the Inca race was heard of. Manco Capac (q. v.) and his wife-sister Ocllo were the children of the sun (Inti), and were sent to earth to instruct the tribes of the Sierra in the 11th c. Their avatar took place on Titicaca Island, whence marching northwards with their adherents, they reached the fertile *bolson* of Cuzco, and there founded the city of that name. Manco died in 1062, after a beneficent reign of forty years, during which he organised the Peruvian nation. The Peruvians, increasing and prospering, soon overflowed the *bolson* of Cuzco into the neighbouring valleys, which they annexed. Tupac Yupanqui pushed his conquests south to the river Maule in Chili, and his son and successor, Huayna Capac (q. v.), carried the victorious Peruvian arms northward to Quito, which he incorporated. Under this warrior, and precisely at the time of the discovery of America by Columbus, the Inca empire attained its greatest extension and the height of its power. The empire extended from 4° N. to 34° S., and from the Pacific on the W. to the forests of the Amazonian valleys on the E. On his death in 1426, Huayna Capac directed that his son and heir, Huascar, should inherit the southern dependencies of the empire, while the northern kingdom of Quito should be the inheritance of another but illegitimate son named Atahualpa (q. v.). The partition of the Inca empire was an innovation in the history of the dynasty, and a civil war was the consequence, in which Atahualpa was victorious. Meantime Pizarro had landed on the coast, and by force and fraud had won astonishing successes. The brave but unscrupulous adventurer crossed the Andes, captured Atahualpa at Caxamalca, and put him to death. For some notice of the romantic adventures and the violence of the Spanish leader, see the articles ALMAGRO and PIZARRO. After the extinction of the Pizarro family the country became a viceroyalty of Spain. The empire, already stripped of its treasures, the gold and silver plate of its temples, palaces, &c., through the rapacity of the Spaniards, was now to suffer territorial diminution through the incapacity of the viceroys. Quito on the N., and a number of provinces on the S., were detached from P. in 1718 and 1788 respectively. Anarchy prevailed in the viceroyalty until, following the example of the other Spanish dependencies in S. America, P. raised the standard of independence in 1820, and was proclaimed a republic, under the presidency of General San Martín, July 28, 1821. Slavery was abolished in 1854. A misunderstanding with Spain which arose in 1863, and was the cause of the occupation of the Chincha Islands in April 1864, was brought to a peaceful conclusion in 1866. On the 22d July 1872, a revolution, led by Don Gutierrez, Minister of War, and his two brothers, broke out. President Balta was taken prisoner and murdered in bed, and Gutierrez appointed himself Dictator; but on the 26th he was assassinated by the populace, his brothers having been previously shot down. On the 2d August 1872, Don Manuel Pardo was elected President. The 'Citizen President,' as he was called, inaugurated a number of movements, the tendency of which was to suppress military despotism and develop the resources and the commerce of the country. General Prado was elected President, August 2, 1876. See Prescott's *Conquest of P.* (1847); *Antigüedades Peruanas*, by Tschudi and Rivero (Vien. 1851); *Guía Política Ecclesiástica y Militar del Perú*, by P. M. Cabello (Lima, 1869); *Travels in P. and India*, by Clements R. Markham (Lond. 1862); *Two Years in P.*, by T. J. Hutchinson (2 vols. Lond. 1874); *Le Pérou, Productions, Finances, &c.*, by A. Chérot (Par. 1876); *P. in the Guano Age*, by A. Duffield (Lond. 1874); and *P., Incidents of Travel and Exploration in the Land of the Incas*, by E. G. Squire (Lond. 1877). Professor Raimondi, after nineteen years' residence in P., is publishing at the cost of the state a great scientific work, *El Perú*, of which the first volume appeared at Lima in 1874, to be followed by six others.

Perugia, the chief town of the province of P. or Umbria, in Central Italy, lies partly on the top and partly on the slope of a group of hills 1300 feet above the valley of the Tiber, and is 74

miles S.E. of Florence by rail. It is a fine old walled town, and contains many buildings of the 14th and 15th centuries. The broad Corso connects the two finest squares—the Piazza Vittorio Emanuele, in which stands the modern Prefecture, and the Piazza del Duomo, in which are the Fonte Maggiore (1277), one of the finest fountains in Italy, and the cathedral of San Lorenzo (the 15th c.), rich in works of art. Along the Corso are the Collegio del Cambio, containing frescoes by Perugino, in which he is said to have been assisted by Raphael, then his pupil, and the Palazzo Pubblico (1281-1333). W. and N. of the cathedral is the Piazza del Papa, with a bronze statue of Pope Julius II. of 1556, and adjoining is the Palazzo Conestabile, which contained the Madonna of Raphael, sold to the Czar in 1871 for 350,000 francs. Among the churches are San Angelo (the 6th c.), San Severo, in the chapel of which Raphael painted his first fresco about 1505, San Francesco dei Conventuali (1230), San Domenico (1304), containing the famous monument of Benedict XI.; San Pietro de Casimensi, a Basilica consisting of a nave, aisles, and transept, with a fine ceiling supported on eighteen columns of granite and marble (1000), and the Oratorio di San Bernardo, with a magnificent polychrome facade (1459-61). The university (1320) has a botanic garden, natural and art history collections, a museum of Etruscan and Roman antiquities, and a valuable picture gallery, consisting of works collected since 1863 from suppressed monasteries and churches, and containing many fine examples of the Umbrian school. P. is the seat of a bishop, and has a lyceum and gymnasium. It has silk, velvet, and woollen manufactures, and carries on a trade in corn, cattle, wool, oil, and wine. Pop. (1874) 16,708, with suburbs, 49,503.

P., the ancient *Perusia*, was one of the twelve Etruscan confederate cities. It fell under the power of Rome B.C. 310. Destroyed during the war between Octavianus and Antony (41), it was afterwards rebuilt under the name of *Augusta Perusia*. It suffered severely during the wars of the Guelphs and Ghibellines, but ultimately obtained the supremacy of Umbria. Obligated to surrender to the Pope in 1370, it was, during the latter part of the 14th c., frequently a papal residence. In 1860 it passed, with the rest of the papal territory except Rome, to the kingdom of Italy. See *La Storia di P.* by Luigi Bonazzi (vol. i. 1875).

Perugia, Lake of (the ancient *Lacus Trasimenus*, Ital. *Lago Trasimeno*), lies within the province of Umbria or Perugia in Central Italy. It is 30 miles in circumference and 8 miles at its greatest breadth, has a depth of 20 feet, and an area of 42 sq. miles. It has three small islands, Maggiore, Minore, and Polvese, and was in the 15th c. emptied into the Tiber by a drain (*emissarius*). Ever since the time of Napoleon I., the project of draining it has been discussed. On its banks the Roman consul Flaminius was disastrously defeated, with a loss of 15,000 men, by Hannibal (B.C. 217). The Sanguinetto, a small stream flowing into the lake, preserves the memory of the fatal battle.

Perugino, so named from having been born (in 1446) near Perugia, but whose natal name was **Pietro Vanucci**, was a distinguished painter of the Roman school, and is further memorable as having been some time the instructor of Raphael. His works, and chiefly his 'Entombment' in the Pitti Palace, are characterised by graceful delicacy of attitude and motion, correct drawing and simple, pleasing expression—qualities which he is believed to have acquired during a temporary residence at Florence, by the study of the great works of Fra Giovanni. In design he is feeble, but in colour often brilliant and harmonious. He died at Castello di Fontignano near Perugia in 1524. P. was the master of the greatest school of Italian art. Raphael was among his pupils.

Peruke. See PERIWIG.

Peruvian Bark is a name given to the different species of *Cinchona* that furnish quinine. In 1859 Mr. Markham was deputed by the Secretary of State for India to visit Peru, and in spite of great difficulties was successful in collecting large quantities of the seeds and plants of some of the most valuable species, at the same time also organising a regular supply. In 1861 he selected the principal localities for plantations on the Nilghiris and other hills of the west side of the Indian peninsula. Through Mr. Spruce, Mr. Cross, and Mr. Pritchett, other species have been introduced, the cultivation has been much extended, and complete success has attended the important experiment. In the Darjeeling district alone, in 1869, over three millions of plants

were in the Government plantations. In British India during 1875-76 the cultivation has yielded a tangible result in a crop of 211,921 pounds of dry bark, and the estimated crop for 1876-77 is 250,000 pounds. The percentage of quinine stems very satisfactory, and the 'peruvian bark' prepared by the official quinquina has been shown to answer as an efficient remedy in most cases of malarious fever.

Peruvian Gooseberry. See *Peruvia*.

Peruwels, a town of Belgium, province of Namur, on the Verne, an upper stream of the Sambre, near the French frontier, and 15 miles W. of Mons by rail. It has important linen industries. Pop. (1873) 7864.

Pesaro (the ancient *Pisaurum*) capital of the central Italian province of Urbino, lies on the Foglia River, a tributary of the Adriatic. It is pleasantly situated, with vineyards, and surrounded by old walls. Among the buildings of the town the most remarkable is the ancient palace of the Dukes of Urbino. Several of the churches contain celebrated pictures, and in the market-place there is a marble statue of Pope Urban VIII. Rossini was born here, and a monument was erected to him in 1864. The principal products are fruit, silk, and wool. The fogs of P. are reckoned the finest in Italy. Pop. (1871) 11,934.

Peschiera, a fortress and small town in the N. Italian province of Mantua, lies at the S.E. end of Lake Garda, on the right bank of the Mincio, where that river leaves the lake, and is a station on the Milan-Vienna railway. It is of great importance as a military position, not only on account of its strength, but from the fact that it forms the N.W. point of the great Italian 'Quadrilateral,' the other three fortresses being Verona, Legnano, and Mantua. P. belonged formerly to the republic of Venice, by which it was ceded to the Austrians in 1796. Shortly afterwards it fell into the hands of Napoleon, who strongly fortified it. The Austrian garrison capitulated here to the Piedmontese on the 31st May 1840. In 1866 P. was annexed, along with Mantua and the Venetian provinces, to the kingdom of Italy. Pop. 2000.

Peshawur (either 'the town of Porus,' or 'full of turbulence'), the chief town of the district and division of the same name in the Punjab, British India, the N.W. frontier station of the army, 14 miles E. of the Khyber Pass, 276 miles N.W. of Lahore and 1468 from Calcutta; pop. (1876) 58,436, of whom the great majority are Mohammedans. The cantonments, 1 mile W., contain an additional 24,676. In 1872 the military force consisted of 1500 Europeans, 3600 natives, 19 guns, and 1080 horses. From the earliest times P. has always been regarded as the key of Hindustan. It has been successively occupied by the Hindus, the Greeks, the Buddhists, the Mohammedans, and the Sikhs; but the population is mainly Afghan. In 1849 it was acquired by the British, with the rest of the Punjab. During the Mutiny of 1857, it was contemplated by Lord Lawrence to abandon P. to the Amer of Afghanistan; but it was firmly held by Herbert Edwards and General Cotton. They disarmed the sepoys; and subsequently, when a regiment rose, 660 men out of a total of 863 were killed within a space of thirty-six hours. Thus was the Punjab frontier saved; and in addition, 3000 irregular Pathans were raised for service in Hindustan. Since that date, three European officers have been killed in the district by Mohammedan fanatics. The chief buildings in P. are the fort, a quadrilateral structure of brick, which contains an important arsenal; and the Ghore Khetri, formerly a Hindu place of pilgrimage, but now a market-place. Most of the houses have underground rooms, used in the heat of summer. The transit trade is very considerable; the imports from Afghanistan being valued at £180,000 in 1872. The imports are silks, furs, nuts, dyestuffs, shawl wool, and wood; the exports, piece goods, indigo, and tea. The manufactures are *lungis* or cotton scarves, a variety of leather articles, and cutlery. P. has a bad reputation for opium-smuggling, fever and cholera being common; but the sanitation of the town has lately been much improved.—The *diviso* of P., which occupies the plain between the Khyber mountains and the river Indus, and is also watered by the Cabul and Swat rivers, has an area of 2497 sq. miles; pop. (1868) 523,151. The total military force in the district is nearly 10,000 men. The climate is continuous; the annual rainfall is only 11 inches, but the soil is fertile where irrigated. The crops are wheat, barley, flax, cotton, and cotton.

Peshito is the name given to the old Syrian version of the Scriptures, which was the first version of the Old Testament made from the original Hebrew for the use of Christians. That it was made from the Hebrew appears from the fact that the original version did not include the apocryphal books, although these were added at a later date. That it was made by Christians appears from the containing of Messianic passages, and from its universal use in the Syrian Church. It received its name from a sample of the text, which was given to the Christians by the Emperor Constantine in the year 313. The version was made in order to distinguish it from the other versions made from the Greek, Hebrew, and Latin. The exact age of the P. is unknown. The Syriac (q. v.), speaks of it in the 4th c. as a common version, and it is then generally received, and even in the 16th c. it was necessary to explain some terms and phrases, as if it were already antiquated. On the other hand, the New Testament part is believed to have been done at the same time as the Old Testament, so that the version must have been made after the formation of the New Testament canon, although it wants the second and third Epistles of John, the second of Peter, Jude, and the Apocalypse. It is thus believed to be not older than the end of the second or the beginning of the third c. The Old Testament P. was first printed in the Paris Polyglott (1645), edited by a Maronite (q. v.), Sionita. The best edition is that of the British and Foreign Bible Society (Ed. Lee, 1823). The New Testament was first printed at Vienna (1555), under the patronage of the Chancellor Widmanstadt. The best edition is Leander and Schaaf's (Lugd. Bat. 2d ed. 1717).

Pest, or Pesth, properly **Buda-P.**, the capital of the kingdom of Hungary, is situated in a sandy plain on the left bank of the Danube, 17½ miles E.S.E. of Vienna by rail, and opposite Ofen or Buda (q. v.), with which it is connected by a suspension bridge (1849) 1246 feet long, and by two magnificent iron bridges for railway and passenger traffic, constructed at a cost of £500,000 and £200,000 respectively. P. comprises five different quarters, the inner or old town; N. of this the Lipotváros (Leopoldstadt) or new town, the finest part; E. the Terézváros (Theresienstadt) and Jozsefváros (Josephstadt); and S. the Ferencváros (Franzstadt). It is well built, with 21 squares, and numerous palaces; and with the many fine erections of recent years, it may compete with Vienna in point of beauty. A row of handsome structures runs along the Danube for 2 miles. The chief buildings of P. are the Nemzeti ('national') Museum (1840), with a library of 180,000 vols., and collection of Hungarian antiquities; the new Opera-house (1873-78), the Nemzeti Színház—'national theatre'—(1840), with accommodation for 2100 spectators; the beautiful Nép Színház (Volks-theater), erected in 1876; and the new Hungarian Academy of Sciences (1860), 90 feet high, and covering an area of 34,308 sq. feet, with three façades in pure Renaissance style, 203, 104, and 109 feet long respectively. The Academy contains the celebrated Esterházy Gallery (transferred from Vienna in 1865), which consists of 800 pictures, 50,000 engravings, and 12,000 drawings. Noteworthy are also the Múvész-Csanok (Kunstlerhaus) (1876), in pure Renaissance style; the Redoute Buildings, in Romanesque-Moorish style; the Custom-House; the Barrack; the Országház (Landhaus, 1866), the meeting-place of the Diet; the Ludovica (1837); the Invalid Hospital; the Város Templom (Stadtpfarrkirche, 1726), the Lipotváros Templom, a Catholic church, the Greek church, and the Synagogue (1857), in Moorish style, the best in Hungary. The finest promenades are the Corso, along the Danube; the extensive wood Város Liget (Stadtwaldchen), one of the most beautiful spots in Europe; the Margitsziget (Margarethen Insel), an islet in the Danube, 4 miles long, where is the famous Sulphur Bath, and where are held celebrated garden concerts. The Margitsziget is also the summer residence of hundreds of people. The Király-haloni (Königshafen), a mound of earth brought from different parts of the country and erected for the coronation of Franz Joseph as King of Hungary, has recently been levelled because it obstructed the traffic, but is to be erected elsewhere. P. has ten Catholic and five other churches, five monasteries, and a University (transferred from Tyrnau in 1780), which in the semester of 1877-78 had 127 teachers and 1175 students; four gymnasia (two Catholic), a commercial school with 15 teachers, a veterinary school, two real schools, and a military academy (established 1872) in the Ludovica. Through the Academy and the

Királyi Society P. is the centre of Hungarian literature and science. It is since 1848 the seat of the Hungarian Government and Diet (to which it sends five representatives), and of the supreme court (Court Royal), and is the commercial capital of Hungary. The most important industries are the preparation of brandy and flour (280 mills), ironworking (especially carriage-wheels), printing, lithography, and the manufacture of silks, cloth, leather, hats, oil, tobacco, and gold and silver articles. There is large trade in corn, wine, 'Sibowizza' brandy made from plums, cattle, wool, plums, hogs' lard, wax, wood, soda, potash, and Hunyady waters. P. has a chamber of commerce, two banks, four important weekly markets, and its four great fairs, annually visited by 30,000 persons, supply with necessary goods the half of Hungary. The Society of the 'Pester Lloyd' contributes greatly to promote trade and industry, and publishes (since 1854) a well-known journal of the same name. East of P. is the Rákóczi, now a race-course, where the Imperial Diets met from the 10th to the 14th c. The pop. of P. is of the most heterogeneous character. Pop. (1870) 200,476 (136,892 Roman Catholics, 39,284 Jews, 11,876 of the Evangelical, and 10,470 of the Reformed Church). 100 years ago it was only 12,000. See J. Hunfalvy's *P. und Ofen* (Darmst. 1858); Köröfi's *P. ar 1870 éven* (Pest, 1871); *Bericht über die Hauptmomente in der Verwaltung der königlichen Freistadt P. im Jahre 1871* (Pest, 1872).

Pestalozzi, Johann Heinrich, the celebrated Swiss teacher and philanthropist, was born at Zürich, 12th January 1746. From his sixth year he was brought up poorly by his widowed mother, and was looked on as a child in whom feeling and fancy were more developed than practical sense. An early visit to his grandfather, a village pastor, filled him with pity for the condition of the poor; at fifteen he became a member of a society to resist official tyranny, and at sixteen, strongly moved by Rousseau's *Emile* and his Gospel of Nature, he resolved to study theology and enter the Church. Erelong he forsook theology for law, but was forced by sickness to give up study, after which he married (1769) a Zürich merchant's daughter, and bought an estate near Habsburg, which he called Neuhof. Here he established an agricultural school for gratuitous instruction of neglected children, which soon included fifty scholars; but P. had no faculty for organisation, and in 1780 he became bankrupt. His *Abendstunden eines Einsiedlers*, which appeared the same year in Iselin's *Ephemeren*, the first public statement of his system of education, was followed by the popular novel *Leinhardt und Gertrud* (4 vols. Basel, 1781), written under great distress in a few weeks. This book was highly successful, but *Christoph and Elise* (1782) was less favourably received. After the removal of the French from Unterwalden (1798) he obtained from his friend Legrand, one of the five directors of the Swiss Republic, a commission to collect in a monastery at Stanz the orphan children of the devastated canton. Here he had soon eighty children, but the return of the French in 1799 broke up the institution. P. then removed to Burgdorf in the canton of Bern, where, with Krüsi of Appenzell, he opened a superior school, whose method he described in *Wie Gertrud ihre Kinder lehrt* (1801). After a short co-operation at Munchen-Buchsee with Fellenberg, he removed to Yverdon in the canton of Vaud, where he founded a large institution, which was soon attended by upwards of 200 pupils and teachers from all parts of Europe. Wholly wanting in administrative ability, P. was in practical affairs entirely dependent on his assistants, and gradually became involved in debt, which the sale by subscription of his *Sämmtliche Werke* (15 vols. Stuttg. and Tüb. 1819-20) barely sufficed to cover. In 1825 he retired to Neuhof, where he wrote his *Schwanengesang* (1826), and *Meine Lebensschicksale als Vorsteher meiner Erziehungsanstalten in Burgdorf und Yverdon* (1826). He died at Brugg, Aargau, 17th February 1827. P.'s power lay in his personality, in the inspired love with which he roused his age to earnestness about popular education. This, he taught, should be based on actual life and its relations, theory and practice going hand and hand. The harmonious development of human nature was to him the end of all education. To P.'s conception of primary teaching the common schools of Europe owe some of their most humane and rational improvements. See Biber, *Beitrag zur Biographie Heinr. P.'s* (St. Gall. 1827); Blockmann, *Heinr. P., Züge aus dem Bilde seines Lebens und Wirkens* (Leips. 1846); Schmidt, *Geschichte der Pädagogik* (vol. iv., Köthen, 1862); Morf, *Zur Biographie P.'s* (2 vols. 1868-69).

Pestilence (Lat. *pestis*, 'plague') signifies, generally, any contagious or infectious disease that is epidemic and fatal, such as the Oriental plague, the sweating sickness, cholera, smallpox, gangrenous pneumonia, &c. In the Hebrew Scriptures several words are translated *P.* or *plague*; but the most erudite biblical critics are of opinion that no special disease is referred to, and that the designation merely refers to their epidemic and fatal character. Several of these pestilences are distinctly referred to special judgments inflicted by God; but, in some cases, the symptoms of the diseases, in so far as they are described, coincide with those observable in severe epidemics of *plague* and of *cholera*. The Latin term *pestis*, which corresponds with the Greek *loimos*, is also used to indicate certain endemic diseases which were attended with a periodic and widespread fatality.

Petal. See COROLLA.

Petard (Fr. from *péter*, 'to explode'), an engine of war for breaking open gates, destroying drawbridges, barricades, and other obstructions, invented late in the 16th c. It consisted of a metal hat-shaped case filled with gunpowder and fixed to a heavy plank which was placed close to the obstruction to be removed. The explosion of the charge was effected by means of a slow match. Gun-cotton enclosed in a bag or box and exploded by means of a detonating fuze has proved an efficient substitute for the old form of P.

Petaurist, a name given to various species of Marsupial mammals, and, among others, to the opossum mouse (*Acrobates pygmaeus*), a creature attaining to the size of a common mouse, and which, like the other members of the family *Phalangistidae* or *Phalangers* (q. v.), is marked by an expansion of the skin of the sides of the body, serving as a kind of parachute, and enabling the animal to take flying leaps from tree to tree. The P. is brown above and white beneath. The Taguan (*Petaurista Taguanoides*), another animal belonging to this family, and also known distinctively by the name of P., inhabits New Holland. This animal is blackish-brown on the upper parts and white below.

Petaurus, a genus of *Marsupial* mammalia belonging to the family *Phalangistidae* or that of the *Phalangers* (q. v.), and including a species known as 'flying phalangers.' The great flying phalanger or Hepoona Roo (*P. Australis*) of New Holland is a familiar species. It is about 3 feet in length. Its colour is a greyish-brown above and white below. Its tail is as long as the body. The squirrel P. (*P. sciurus*) of Norfolk Island is another species. Its length is about 16 inches, and its fur is of a brown colour tinted with grey. The tail is long and bushy, and the wing-membrane is well developed. The aerial P. (*P. Arcti*) is the size of a small rat, and exceedingly graceful in its leaping.

Petchora, or **Petchiura**, a river of N. Russia, rises in the Ural Mountains, at a height of 3201 feet, flows first N. with a winding course through the governments of Perm, Vologda, and Archangel, then, after a wide sweep to the S.W., again N. to the Arctic Ocean, which it enters by a great estuary. The P. is about 1380 miles long, and is navigable for two-thirds of its course. Its chief tributaries from the right are the Ilytch and Ussa, and from the left the Ishma and the Zylma (with the tributary Pishma). Its basin is wild and uncultivated, and in part covered by dense larch forests.

Petechiae, in medicine, are spots of a dusky crimson or purple colour, resembling flea bites, which appear on the skin in certain diseases. They appear to be dependent on a lowered vitality of the system which in some way affects the blood, breaking up the red corpuscles and allowing their contents to transude into the tissues. P. are symptoms of several very serious diseases, as purpura, scurvy, typhus, plague, &c., and occasionally appear in very severe cases of small-pox, measles, and scarlet fever. They are sometimes called *stigmata*, *vibices*, and *ecchymoses*.

Peter, one of the twelve apostles, and the son of Jona, a fisherman of Capernaum, was brought by his brother Andrew to Jesus (John i. 40-42), who gave him the name of Cephas (Aram. *ceph*, Heb. *ceph*, 'a rock'), which surname, in its Greek equivalent (Gr. *petros*, 'rock'), superseded his original name of Simon. His after life is divided into two periods by the crucifixion of Christ. In the former period he exhibited much rashness in forming opinions and forwardness in avowing them, great boldness on the impulse of the moment, which,

however, dwindled into cowardice when the danger was better realised, and a great deal of fickleness combined with an ardent attachment to his Master and undoubted zeal (cf. Mat. xiv. 28-31, xvi. 22-23, and 28-29, Mark viii. 29, John xiii. 36-38). After the crucifixion and his own fall P. appears a changed man. His former impulsiveness, rashness, and forwardness are replaced by dignity, firmness, sagacity, and prudence; and his attachment to his Master and his cause is exhibited less in word than in deed. Like James and John, P. enjoyed a peculiar intimacy with Jesus (cf. Mark x. 37, x. 2, xix. 33). There can be no doubt also that he held the first place among the apostles during the lifetime of their Master, as well as afterwards. Roman writers have always magnified this pre-eminence of one who, they assert, was the first bishop of Rome, in seeking to establish the supremacy of the see of Rome over the rest of the Church; and Protestant writers, in their opposition to Papacy, have as unfairly denied to him the pre-eminence which he did possess till he disappears from sacred history after the council of Acts xv. Of his after life nothing is known for certain. Inferences from the Petrine Epistles have been repeated by uncritical writers as history. Thus he is said to have laboured in Asia Minor, to have visited Babylon and Corinth, and to have suffered martyrdom (crucifixion head downwards) at Rome. Eusebius repeats the assertion of the Clementine Homilies that he came to Rome in the year 42, and that he was superintendent of the church there for twenty (otherwise twenty-five) years; and Jerome makes him bishop for the same time. The whole story is mere tradition, and the legend of P.'s crucifixion is obviously coloured by a desire to illustrate 'the ruling passion strong in death;' but there is considerable difficulty in believing that P., the foremost Christian of his time in position and authority, could have disappeared from the world without leaving any trace or memorial of himself.

Peter, Epistles General of, are two in number. They stand on a very different footing. The authenticity of the *First Epistle* is attested by external evidence both ancient and weighty, and it is among the books which were admitted into the canon from the first. The internal evidence that P. was the author has been much controverted. Some have endeavoured to show that the writer was acquainted with and made a certain use of Pauline ideas, phraseology, and doctrine, as well as those of the Epistles of James and John. Accordingly, while the Petrine authorship is maintained by many critics, the theory held by others is that the writer was an *eklectic*, 'who wished to present the practical side of Paulinism, and whose free elaboration of existing ideas and writings resulted in a peculiar letter.' As to the time when the Epistle was written critics are greatly divided; it has been fixed at almost any time between 46 A.D. and the beginning of the 2d c. The Epistle itself professes to have been written from Babylon; but this is probably to be understood mystically as Rome. The *Second Epistle* is in a different position from the first, both as regards external and internal evidence for the Petrine authorship. It was not received into the canon till the Council of Hippo (393), and the controversy regarding its authenticity has been revived in modern times. It is asserted that the writer made use of the Epistle of Jude (cf. ii. iii. with Jude), partly copying and partly imitating; that there is a manifest anxiety on the part of the writer to make himself known as the Apostle Peter (cf. i. 1, 13-18, iii. 1, 15), although once, in using the words of Jude (17) he unconsciously lays aside his assumed character (iii. 2); that there are several indications of a post-apostolic origin (e.g., the title 'Scriptures,' iii. 16, the doubts about the second coming of Christ, iii. 4, 10-12, the use of *heresy* already applied to doctrine, ii. 1); and that the difference in diction and style between the two Epistles is so great as to imply different authors. On these grounds many critics abandon the Petrine authorship, although there are not wanting able scholars who maintain it. There are no clear indications in itself when it was written. If written by P., it must have been before 64 A.D.; but some critics place it as late as 170 A.D.

Peter I, Alexie'vitch, Emperor of all the Russias and founder of the greatness of Russia, commonly called **Peter the Great**, son of the Czar Alexei Mikhailovich by his second marriage, with Natalia Naryshkova, was born at Kolomanskoe-Selo, a village near Moscow, 20th May 1672. By right he should have succeeded his elder half-brother, Feodor III., in 1682, but he was forced to yield to the ambitious

intrigues of his half-sister Sophia, who, aided by a revolt of the Strelitzes which she had excited, divided the government, under her own guardianship, between P. and his weak-minded half-brother Ivan. Sophia ruled with her favourite Wasilii Golitsin as first minister, while P. was kept in isolation from a Cossack named Lefort, who inspired him with a love of the art of war and of Western civilisation, and quietly contributed to develop a manly, reforming spirit, though suffering him to run into gross sensual excesses. In 1688 P. married a noble Russian lady, Eudoxia Feodorovna Lopuchin. Sophia, perceiving his great facilities, and fearing she would soon become superfluous, resolved, with the aid of the Strelitzes, to rid herself of P.; but her plot failed, and she was forced to enter a cloister. P. now (1689) became sole ruler, at first contented himself with the imperial title. All his energies were now bent to introduce Russia, hitherto little differing from an Asiatic state, among the Great Powers of Europe, and bring its half-barbarous people under the influence of European civilisation. With the aid of Lefort and a Scotchman named Gordon, he formed an army on the European system, invited skilled workmen from abroad, and laid the foundation of a fleet. After a war with Turkey (1696) in which he subdued Azov (formally yielded to him at the Peace of Carlowitz in 1699), and the suppression of a new conspiracy against his life by the Strelitzes and certain Russian nobles in 1697, P. undertook in April of the latter year a journey to Germany, Holland (where, as a common workman at Zaardam, he learned ship-building), and England, but was suddenly recalled from the latter country to suppress another insurrection of the Strelitzes. On his return he found they had been already quelled by Gordon; but he used the opportunity to extirpate this turbulent corps, putting them to death *en masse*. His wife, whom he perhaps unjustly believed to be privy to the conspiracy, was divorced and driven to a cloister. From 1700 to 1721 P. was an active member of the combination against Karl XII. (q. v.) of Sweden, and prosecuted with great patience his favourite plan of forming a great Russian harbour on the Baltic, as through the Turkish war he had gained access to the Black Sea. At Narva, in 1700, he felt the superiority of the Swedes in the art of war, but he prudently availed himself of Karl's absence with his army in Poland to overrun the Swedish provinces on the Baltic, and founded (1703) the new capital, St. Petersburg. His victory over Karl at Pultava (q. v.) in 1709 was his crowning success. During the Swedish war P. became acquainted with Catharine (see CATHARINE I.), whom he married privately (1707), and afterwards publicly (1712), she, in a second war with Turkey, having delivered him from great distress—surrounded at the river Pruth in an incursion into Moldavia—by bribing the Grand Vizier, so that P. escaped from the utmost danger with the loss of Azov (1711). At the peace of Nystad in 1721 P. obtained from Sweden the provinces of Ingermanland, Esthonia, Livonia, and Viborg in Finland. In the same year he took the title of 'Emperor of all the Russias,' offered him by the Senate, a body which P. had created to check the power of the Bojars. He had already (1720), in order to curb the clergy, who kept the common people in ignorance, abolished the patriarchal dignity, and established the 'Holy Administrative Synod,' of which he himself was the head. In 1722 he decreed that the appointment of his successor should henceforth rest with the emperor himself, a step occasioned by his unfriendly relations with Alexei, his son by his first marriage, to whom many that were dissatisfied with P.'s thoroughgoing reforms attached themselves. After a bloody war (1722-23) P. tore from Persia the provinces of Ghilan, Mazanderan, and Astrabad, with the towns Derbent and Baku. His reforms extended to all departments of the state; he liberally supported manufactures and mining, promoted trade by making harbours and canals, and founded several higher schools, the Academy of Sciences at St. Petersburg, &c. But general diffusion of intelligence was hindered by serfdom, for P. did nothing directly for the peasant class, and even the culture of the higher ranks of the people was of a merely external kind. The French fashions and ceremonies of the court were constantly broken through by the natural rudeness consequent on P.'s education and surroundings. He had a powerful helper in the government in Menchikoff (q. v.). A painful straggle, chiefly due to his immoderate use of brandy, with a severe chill caught by leaping into the water in the midst of winter to help a stranded ship, caused his death (8th February

1725), in his fifty-third year. The mighty task which P. set himself was to substitute for the miserably incongruous administration of the old Muscovite Czar a symmetrical bureaucratic machine, modelled on the newest principles of political science. For this work he had no technical knowledge, no requisite material, no suitable foundation, nothing but his own unconquerable genius and Titanic energy. His attempts at construction were little more than a series of failures; and in the midst of his labours he was snatched away suddenly, bequeathing the great task to his successors. A supreme ascendant by position and nature, he was regardless of the claims of noble birth and long pedigree, and threw open the service of the state to men of all ranks. Many of his chief coadjutors were not even of Russian family. 'Count Yaguzhinski, long one of the foremost officers in the state, was the son of a poor sacristan; Count Devier was a Portuguese by birth and had been a cabin-boy; Baron Shafirof was a Jew; Hannibal, who died with the rank of Commander-in-Chief, was a negro who had been bought in Constantinople; and his Serene Highness Prince Menchikoff began life, it was said, as a baker's apprentice.' The dignified orthodox Muscovites were scandalised by P.'s wanton outrage of all the traditional conceptions of propriety and etiquette, and some of them suspected that he was not the Czar at all, but Antichrist in disguise. But P. served the state with undagging zeal—as a common artisan when he thought it necessary—and he insisted on all his subjects doing likewise, under pain of merciless punishment. And if he was arbitrary and oppressive, he freely exposed himself to danger and drudgery. By his first marriage P. was the father of the Alexei mentioned above, and by his second of a daughter Anna (married to Duke Karl Friedrich of Holstein-Gottorp, from whom is descended the present imperial family), and the Empress Elizabeth. On the centenary of his accession a colossal equestrian statue of P. by Falconet was uncovered at St. Petersburg. It is placed on a large block of granite, with the inscription, 'Petro Primo Catharina Secunda MDCCCLXXXIII.' See Halem, *Biographie P.'s des Gr.* (Münst. and Leips. 1803-5); Bergmann, *P. der Gr. als Mensch und Regent* (Riga and Mittau, 6 vols. 1823-30); Ségur, *Histoire de Russie et de Pierre-le-Grand* (Par. 2d ed. 1829); Ustrakov, *Istoria Zarstvovaniia Petra Velikago* (St. Peters. 6 vols. 1855-63), as also the Biographies by Gordon, Voltaire, &c. *The Diary of P. the Great till the Peace of Nystad* is very important, and Mackenzie Wallace's *Russia* (1877) contains a good account of his life work.

—P. II., Alexievitch, Emperor of all the Russias, 1727-30, son of Peter the Great's son Alexei and Charlotte Christine Sophie of Brunswick, born 23d October 1715, ascended the throne with the aid of Menchikoff, and was ruled first by him, and after his banishment by Ivan Dolgorouki. His short reign was uneventful. He was about to marry Dolgorouki's sister, when he was cut off by small-pox (9th February 1730).

P. III., Feodorovitch, Emperor of all the Russias, son of Duke Karl Friedrich of Holstein-Gottorp and Anna, daughter of Peter the Great, called properly Karl P. Ulrich, was born at Kiel, 21st February 1728. He became Duke of Holstein-Gottorp on his father's death in 1739. After his aunt Elizabeth (18th November 1742) appointed him Grand Duke and her successor, P. joined the Greek Church, and married (1st September 1745) his second cousin, Sophie Auguste Frederika of Anhalt-Zerbst, the afterwards so famous Catharine II. He ascended the throne on Elizabeth's death (5th January 1762), and soon became hated through unpopular undertakings abroad (his connection during the Seven Years' War with Friedrich II. of Prussia, for whom he had a great admiration, and his preparation for war with Denmark to regain the Gottorp part of Holstein), and his arbitrary and uncalled-for changes at home. He relaxed the system of P. the Great, and conferred various privileges on the noblesse, abolishing the principle of obligatory service in their favour in 1762. His conduct to his consort was heartless, and with his Holstein officers he gave himself up to debauchery and excess. A conspiracy was formed against him, and after a reign of half a year he was in the night of the 8th July deposed and imprisoned, and on the 17th was murdered at the Castle of Ropsha, near St. Petersburg. The partial abolition of obligatory service had naturally revived among the peasants the hope of emancipation from serfage, and they clung to the belief that the Czar had escaped the conspirators and was in hiding. A Cossack pretender, called Pugatchef, appeared on the Don, and began a bloody campaign with the idea of found-

ing a peasant empire (*mushitskoe tsarsto*), but he had neither tact nor energy enough to realise such a scheme. After a series of defeats he was taken prisoner, and the revolt was quelled. See Lavaux, *Histoire de Pierre III.* (Par. 3 vols. 1799).

Peterborough, a city and episcopal see of England, in Northamptonshire, on the N. bank of the Nene, and on the border of the fens, 76½ miles N.N.W. of London by the Great Northern Railway. Its great architectural feature is the cathedral, a regular cruciform building of Norman and Early English character, with a remarkably beautiful W. front, formed by three deeply recessed arches, supported by triangular piers faced with clustered shafts, and surmounted by a lofty and richly-sculptured pediment and cross. This noble structure was mainly erected 1117-1237, but is in part of much later date, the E. aisle, which is in Perpendicular style, not being completed till 1528. At each end of the W. front is a lofty turret 156 feet high, flanked at the angles by shafts, and crowned with spires. The central tower or lantern is 150 feet high. The wooden inner roof of the nave and great transepts is decorated with paintings of kings, bishops, and grotesques. Having an extreme length of 476 feet, the cathedral is 203 broad at the great transepts; the nave and aisles are 78 feet broad, and the height of the inner roof 78 feet. At the W. end there is a range of interesting monastic buildings. The cathedral contains the tomb of Catharine of Aragon; but the remains of Mary Queen of Scots were removed hence to Westminster Abbey in 1612. Other buildings are St. Mary's Church, in First Pointed style (1861), a training college for the dioceses of P. and Lincoln (1866), and a corn exchange in Italian style. P. has large steam flour-mills and railway works, while there is an increasing trade in grain, coal, timber, lime, bricks, &c. Besides the Great Northern Railway, the North-Western, Eastern Counties, and Midland lines contribute to the traffic of P., which is also accessible to small vessels by the Nene. Two very important fairs are held here on the 10th July and 2d October respectively. P. sends two members to Parliament, and publishes two weekly newspapers. Pop. (1871) 17,434. A Benedictine abbey was founded here in the second half of the 7th c. by the Mercian king Penda, son of Penda, and his brother and successor, Wulfere. It was originally called *Meadershamstede* ('the meadow homestead'), and the circumstances relating to its erection, consecration, and endowment, are recorded at unusual length in the *Chronicle*. In 870 this abbey, along with those of Crowland and Ely, was destroyed by the Danes, only to be restored on a grander scale in 966-971. The town was sometimes called Gildenburgh, because a part of the minster roofs had been gilded by Abbot Leofric; but as the great church was dedicated to St. Peter, it finally took and retained the name of P. At the dissolution of religious houses (1537), P. Abbey, among the most magnificent then existing, was selected as the seat of one of the new bishops, and the buildings were preserved entire. During the Civil War the Parliamentary forces defaced the monuments in the cathedral, destroyed part of the cloisters, the chapter-house, and the episcopal palace. See *History, Topography, &c., of Northamptonshire*, by Francis Whellan & Co. (2d ed. 1874).

Peterborough, Earl of. See MORDAUNT, CHARLES.

Peterhead, a seaport of Aberdeenshire, and the most easterly town in Scotland, is built on a rocky peninsula 3 miles N. of Buchanness Lighthouse, 44 miles N.N.E. of Aberdeen by rail. Part of the town called Keith Inch is an island, separated from the rest of the town by a canal between the S. and N. harbour, over which there is a drawbridge. On this island there formerly stood a castle of the Keith family. Earl Marishall created P. a burgh of barony in 1593. The lands were forfeited in 1715, and in 1728 were purchased by the Merchant Maiden Hospital, (one of the Edinburgh Merchant Company corporations) for £3420, the annual rental being £245. The rental of this and some subsequent purchases is now (1878) over £5000 per annum; but this return is the result of large expenditure and liberal improvements by the governors of the Merchant Maiden Hospital, who are still the superiors of the town and proprietors of the estate. The valuation of the burgh for 1877 was £29,718. In front of the townhouse stands a bronze statue of the celebrated Field-Marshal Keith of the Prussian service. The statue was the gift of the present Emperor of Germany; the pedestal was subscribed for by the inhabitants. During the last few years a number of important buildings have been

erected, a music hall, courthouse, several new churches, &c. A pretty cemetery of about 3½ acres has been made by the Merchant Maiden Hospital. It was formally opened on 15th July 1869, and the governors have expended about £3000 upon it. All the buildings in P. are constructed of the well-known red granite for which P. is famous. Granite quarrying affords work for many hundreds of men; there are two polishing works, at which many public monuments for all parts of the world have been executed. The N. and S. harbours are connected by a canal, which enables vessels to leave in different winds. A new or third harbour, with a new concrete pier, called Port Henry harbour, was completed in 1878, and arrangements are being carried out for deepening the S. harbour, which will then enable vessels to enter at all states of the tide. P. has long been the chief seat of the Greenland and herring fisheries. Between 700 and 800 boats usually fish, but when the harbour improvements are completed there will be accommodation for a much larger number. There are several shipbuilding yards, at which in 1876 four vessels of 838 tons were built. The present tonnage of the port is about 7000 tons. In 1876 there cleared 798 vessels of 65,834 tons, and entered 800 of 63,717 tons. There is a large export trade in granite, grain, fish, &c. Pop. (1871) 8535; (1878) over 10,000. Along with Elgin, Kintore, Cullen, Banff, and Inverurie it sends one member to Parliament; it is also the returning burgh for East Aberdeenshire. In the vicinity are the interesting ruins of Ravenscraig and Inverurie, and the far-famed Bullers of Buchan. The river Ugie falls into the sea about 2 miles N. of P., and affords excellent rod-fishing for several miles up the river.

Peterloo Massacre, a name given to the dispersal by an armed force of a large popular gathering which met at St. Peter's Field, Manchester, for the purpose of promoting parliamentary reform. Six persons were killed and several others wounded. See Miss Martineau's *History of the Thirty Years' Peace*.

Petermann, August, a celebrated geographical writer and cartographer, was born at Bleicherode, near Erfurt, April 18, 1822, and educated first at Nordhausen, and after 1839 at the geographical school founded by Berghaus at Potsdam. After working for Berghaus, he went to Edinburgh in 1845, and was there employed on Keith Johnson's physical atlas. In 1847 he removed to London, and became known as a contributor to the *Athenæum* and *Encyclopedia Britannica* on such subjects as the Franklin search, the travels of Barth, Overweg, Vogel, &c. He was appointed first editor of the *Mittheilungen aus Justus Perthes Geographischer Anstalt* in 1854, and has since rendered that periodical famous throughout the world for scientific method and thoroughness, as well as for freshness and range of information. Many of its maps are from his own hand, and on the subject especially of Arctic exploration he has contributed many valuable articles (see also *Macmillan* for January 1877). Of his colleagues, the best known are Ernst Beem, and Hermann Wagner (now a professor at Königsberg). Among P.'s finer maps are those of Australia (9 sheets) and the United States (6 sheets), many in Stieler's *Hand Atlas* (new ed. 1874), and one of the Eastern States of the American Union in the *Mittheilungen* (Part xi., 1877).

Peter's, St., Church, at Rome, stands on the site of a five-aisled basilica, erected by Constantine and Helena (306) over the grave of St. Peter and near the scene of his martyrdom. This older structure, in which Karl the Great was crowned by Leo III. (800), had become so dilapidated that in 1450 Nicholas V. began to build a new tribune from the design of Rossellini. The work languished for fifty years after Nicholas's death, till Julius II. committed its execution to Bramante, and laid a new foundation-stone, April 18, 1506. Bramante was succeeded by Raffael, Peruzzi, Michael Angelo (1546-64), Vignola, and Giacomo della Porta, and the new church was consecrated by Urban VIII., November 18, 1626. At the close of the 17th c. £10,000,000 had been expended on St. P., and the new sacristy added by Pius VI. (1775-99) cost £180,000 more. The present expense of maintenance is about £7500 a year. Built in the form of a Latin cross, St. P. is the largest and grandest of all the churches of Christendom. It covers an area of 26,163 sq. yards, the total length of its interior being 205 yards, of the transept 150 yards; whilst the nave is 150, and the Dome (q. v.) 435 feet in height. The facade is 175 yards long and

165 feet high. Within, the church contains 30 altars and 148 columns, and is adorned by countless statues, mosaics, and other decorations. Among the most striking objects are Bernini's bronze baldachins, 95 feet high, surmounting the High Altar; the bronze statue of St. Peter, a work of the 5th c.; a 'Pietà' by Michael Angelo; and the monument to Pius VI. by Canova, to Pius VII. by Thorwaldsen, and to Pius VIII. by Tenerani. See Fergusson's *History of Ancient and Modern Architecture* (4 vols. Lond. 1875), and *St. Peter's and St. Paul's* by E. Oldfield (Lond. 1877).

Peters, Hugh, the regicide, born at Fowey, Cornwall, in 1559, entered Trinity College, Cambridge, and graduated M.A. (1622). He first went on the stage, then taking orders, held the lectureship of St. Sepulchre's, London, till an intrigue with a married woman forced him to fly to Rotterdam, whence in 1634 he sailed for America. He was pastor for five years at Salem, returned to England in 1641, became Cromwell's chaplain, and took an active part in the trial and condemnation of Charles I. Kennet even maintains that he was one of the masked executioners. At the Restoration P. was exempted from the Act of Indemnity, and hanged with nine others, October 16, 1660. He was author of *Lectiones in Psalmos* (1647), and *Last Legacy to an Only Child* (1660). See Samuel Peters' *History of the Rev. H. P.* (New York, 1807).

Petersburg, a city and port of entry in Virginia, U.S., on the S. bank of the Appomattox River, 12 miles from its mouth, and 23 S. of Richmond by rail. It has twenty-four churches, a public park called Poplar Lawn, a theatre, four newspapers, and manufactures of tobacco, cotton goods, and iron and wood wares. In 1875 it exported 3,266,804 lbs. of tobacco, 36 per cent. of the whole freight export of that article from the United States; the revenue paid on the tobacco manufactured in the city was \$812,345. The exports also included 26,240 barrels of flour, 39,648 bales of cotton, and 108,000 bushels of peanuts. Pop. (1870) 18,950. Its heroic defence by General Lee against the Army of the Potomac under Grant, the last great event in the Civil War, procured for it the title of 'the last city of the Confederacy.' The actual siege extended from 19th June 1864 to 3d April 1865. 'The bloody battle of the crater' (30th July) was only one of a series of attempts to take the city by storm. Six days after evacuating, Lee surrendered at Appomattox, and thus ended the war.

Petersburg, St. See ST. PETERSBURG.

Peter's College, St., Cambridge, commonly known as Peterhouse, is the oldest of the Cambridge colleges, having been founded by Hugh de Balsham, Bishop of Ely, in 1257. It is governed by a master, and has fourteen fellowships and twenty-one scholarships, viz., four of £80, nine of £60, one of £50, four of £40, and three of £30, all of them tenable till their holders are of standing to take their D.A. The fellowships, three of which are clerical, are tenable for life by unmarried, and for twelve years by married fellows. St. P.'s C. presents to ten livings, and in 1877 had 156 members of the senate, 37 undergraduates, and 228 members on the boards.

Peter's Pence. When Christianity was introduced into England from Rome, the English began to make pilgrimages to that city, and sent their sons thither to be educated. For the support of these pilgrims and the education of the clergy, Offa, the great Mercian king (758-796), imposed on his subjects a tax of a silver penny, payable by every family possessing land or cattle of the yearly value of thirty pence, which was called St. Peter's penny; the Pope being identified with St. Peter, who was understood, rightly or wrongly, to have been the first Bishop of Rome (see ST. PETER). At a later period this tax took the form of an annual tribute to the Pope, which in the time of King John amounted to £199, 8s.; and which was paid by other countries as well as England. The refusal on the part of the southern countries of Europe to continue the payment of P. P. was one of the first overt symptoms of that dissatisfaction with Rome which began to be expressed in the 15th c., and culminated in the Reformation. In England Edward III. first refused to pay the tribute, which was finally discontinued under Henry VIII. In modern times, especially since the Pope was deprived of his temporalities, P. P. has been to a certain extent revived under the form of voluntary contributions from the faithful.

Petersfield, a town of Hampshire, 18 miles E. by S. of Winchester, and a station on the South-Western Railway. It is clean, well paved and lighted, and has two banks, a literary institute, corn-exchange (erected 1866), and an educational institution called Churcher's College, founded 1722, with an income of £600, for the education and maintenance of fourteen boys. The church, which is Norman, has a square tower with six bells, and dates from the 12th c. P. returns a member to Parliament. Pop. (1871) 6104.

Peter the Hermit, born at Amiens about 1050, served under the Comte de Boulogne in the Flemish war (1071), and afterwards married, but his wife dying, he retired to a monastery, and thence to a hermitage. In 1093 he made a pilgrimage to the Holy Land, where his zeal was kindled by the sight of the Holy Sepulchre in the hands of infidels and of their cruelty to Christian pilgrims. Furnished by the Patriarch Simeon with credentials to Pope Urban II. and the princes of Christendom, P. traversed a great part of Europe preaching the first Crusade in churches, highways, and market-places. At the Council of Clermont (1095) his wild harangue drew from the assembled multitude the cry of 'God wills it.' Early in 1096 the second popular expedition, headed by P. himself, followed in the wake of Walter the Penniless, fighting its way through Hungary and Bulgaria to Constantinople, where the Greeks gladly furnished the means of transport across the Bosphorus. On the plain of Nicæa, Christians and Mussulmans alike barred the further advance of the undisciplined rabble, and P. led back to Constantinople 3000 out of 60,000 followers. With this remnant he joined the army of Godfrey de Bouillon, and shared in the victorious march on Antioch. There, in 1097, some of the Crusaders resolved to return home, P. among the number, but Tancred withheld him, reproaching him with abandoning the enterprise he had himself originated. Accordingly P. took part in the capture of Jerusalem (1099), and was chosen by Arnould, the new patriarch, for his vicar-general. When he returned to Europe is not known, but he died in the Abbey of Neu-Montier, which he had founded at Huy in Belgium, on 7th July 1115. See CRUSADES; Schachert's *Peter von Amiens* (Berl. 1819); and H. Prat's *Pierre l'Ermite et la Première Croisade* (Par. 1840).

Peterwardein, one of the strongest fortresses of Austria, in the Servian-Banatic frontier, on a peninsula formed by the Danube, and on its right bank, 42 miles N.W. of Belgrade. It is connected by a fortified bridge of boats with the Hungarian town of Neusatz, on the opposite side of the Danube, which is here 700 feet wide, and 50 to 60 feet deep. On a rock, of which three sides are isolated, stand the upper fortress and hornwork, and at its base the lower, including the town, which consists of one main street, and two parallel with it. The principal buildings are the arsenal, with many Turkish trophies, the commandant's residence, and the Catholic church. The fortress is capable of containing 10,000 men. Pop. of the town (1869), 5497. P. is said to have derived its name from Peter the Hermit's having marshalled here the armies for the first crusade. It was the scene of Prince Eugene's victory over the Turks, 5th August 1716.

Petherick, John, an African traveller, of English parentage, was born in 1820, entered the service of Mehemet Ali as a mining engineer in 1845, and became a merchant in 1849 at Khartum, where he was made British consul. He subsequently made two journeys (1857-58 and 1861-63) in the basin of the Upper Nile and the Bahr-el-Ghazal, its great western tributary. He published *Egypt, the Soudan, and Central Africa* in 1861, and has since sent home much valuable geographical intelligence. Schweinfurth says P. was 'the first to open mercantile transactions with the tribes of those remote regions.'—**Catherine P.**, the wife and the faithful companion of the traveller on his last journey, died at St. Goran, Cornwall, in 1877.

Petiole. See LEAVES.

Petion de Villeneuve, Jérôme, was born at Chartres in 1753, and first comes into notice as an advocate, who was returned for his native town to the States General of 1789. Having a turn for diffuse speeches, he bored his way into notice and even obtained a considerable hold upon public opinion, his advocacy being associated with the most extreme form of republicanism. With Mirabeau he frequently debated, outstripping him in hatred of monarchy and in vehemence for the rights of men. P. was one of the most unbridled speakers against Marie

Antoinette, and a conspicuous Jacobite. At the end of 1790 he was elected parliamentary president. Withal he earned among his friends the title *P. le Vertueux*. He was appointed (June 1791) president of the criminal tribunal of Paris, and was one of the deputies who brought back the king from Varennes, a task which he accomplished with singular brutality. On the 30th September he received the honours of a triumph at the end of the sittings of the Assembly, and on the 14th of the following November he was elected Mayor of Paris, the court assenting in order to frustrate Lafayette. His administration lasted a year, and was marked by every incitement to revolution. After the opening of the Convention P. joined the Girondists, and being impeached by Robespierre, was prosecuted and imprisoned. He escaped (1794), fled towards Bordeaux, and in the month of June was found dead, half eaten by wolves, in the neighbourhood of St. Emilion. The year before his death appeared the *Œuvres de P.*, containing his speeches and some small political works. See Regnault-Warin's *Vie de P.* (Bar-le-Duc, 1796), and the histories of Thiers, Louis Blanc, Michelet, and Lamartine.

Petition. The right of the English subject to petition the Crown or either House of Parliament appears to have been held from very early times a radical principle of the political constitution; but in the struggle during the 17th c. between the Crown and Commons, indirect endeavours to check the practice were made on both sides. Thus the first Parliament after the Restoration, remembering those tumultuous assemblages which had overawed their predecessors in 1641, passed a law against disorderly petitions. It provided that no P. should be presented for alteration of any law affecting the Church or the State without the order of three justices of the county, or that of the majority of the grand jury. A scheme for compelling the Crown, in the reign of Charles II., to assemble Parliament, by pouring in petitions from all parts of the kingdom, was thwarted by that monarch in an artfully drawn up proclamation (see *London Gazette*, 12th October 1679), in which, without controverting the principle of right, he shows his dislike to the practice, and encourages magistrates to suppress it. Since the Revolution of 1688, however, there has been no attempt to interfere with the subject's right of P. It must, however, be exercised with decorum, and respectfully. The P. requires to be endorsed and presented either by a member of the House to which it is addressed, or by an important municipal corporation. Petitions to the House of Commons are usually referred to a committee, who report regarding them. There are some cases in which a P. will be considered by the House of Commons only on the recommendation of the Crown. These arise chiefly when the P. regards public revenue. In earlier times, petitions were chiefly addressed to the House of Lords, and were more usually for the redress of private than of public wrongs.

Petition of Right, a statute so called from its being drawn in the form of an Act of Parliament, was prepared in the famous meeting of the House of Commons in 1628. It was based upon four grievances—the exaction of money under the name of loans, the commitment of those who refused compliance, billeting of soldiers upon private persons, and commissions to try military offences by martial law. The statutes which had established the liberty of the subject were recited in it, and their most recent violations enumerated, after which occurred the prayer, 'That no man hereafter be compelled to make or yield any gift, loan, benevolence, tax, or such like charge, without common consent by Act of Parliament, and that none be called to answer or take such oath, or to give attendance, or be confined or otherwise molested or disquieted concerning the same, or for refusal thereof; and that no freeman in any such manner as is before-mentioned be imprisoned or detained; and that your majesty will be pleased to remove the said soldiers and mariners, and that your people may not be so burthened in time to come; and that the aforesaid commissions for proceeding by martial law may be revoked and annulled; and that hereafter no commission of the like nature may issue forth to any person or persons whatever to be executed as aforesaid, lest by colour of them any of your majesty's subjects be destroyed or put to death contrary to the laws and franchises of the land.' It was conceded 26th June 1628. See Hallam's *Constitutional History of England*.

Petitiō Principiī (Lat. 'a begging of the principle' or point in dispute), is the name given in logic to an extremely

common kind of faulty reasoning, in which the conclusion to be drawn is assumed in the premises of the syllogism.

Petőfi, Sándor (Alexander), a celebrated Magyar poet, was born of poor parents at Kiskőrös, Cumania, Hungary, 31st December 1822. His youth was spent first as a common soldier, then as a strolling player. In 1843 he first attracted public attention through some poems in journals, which were collected and published in a volume in 1844, and were soon followed by the mock-heroic poem *A Helység Kalapácsa* ('The Village Hammer'), the historical epic *János Vitéz* ('The Hero Janos,' 1845; Ger. trans. by Kertbeny, Stuttg. 1850), and several volumes of lyrics. From 1844 he was employed as co-editor of *Dinallap*, and in 1847 with Maura Jókai undertook the editorship of *Életképek*, into which he introduced poems and stories of peasant life. His romance *A 'Végh' kőtele* (Pest, 1846; Ger. trans. Halle, 1852) was less successful. He also wrote for the stage his *Tiger und Hyäne* (Pest, 1846) and a translation of Shakespeare's *Coriolanus* (1848). P.'s poems, especially his lyrics, are marked by strong colour, and are instinct with passion and fulness of life. His background is the scenery and popular life of Hungary, and shows imaginative power in every detail. He is the Burns of Hungary, and by far the richest and raciest of its poets. A patriotic Magyar, he was the leader of the Pest youth in 1848; his *Most vagy soha* ('Now or Never') was the song of the revolution. During the war P. acted as adjutant to Bem. Mészáros's displeasure at his unsoldierlike appearance induced him to retire in May 1849, but on the approach of the Russians he returned to his former post, and fell (31st July 1849) at the battle of Szegedvár. A large number of the spirited war-songs of P. are collected in *Hangok a multból* (1851). His most important poems have been translated into German by Kertbeny (4th ed. Frankf. 1866), Szarvady and Hartmann (Darmst. 1851), and Opitz (2d ed. 2 vols. Frauenfeld, 1868); and into French by M. Dozon (Par. 1877). Opitz also translated his last poem (*Der Apostel*, Par. 1873). Don Ramon L. Mainez has published (Cadiz, 1877) a Spanish translation of a number of his shorter pieces. His biography has been written by Chaffin (Par. 1861) and by Opitz (Frauenf. 1868). See Sir John Bowring's translation of *Selected Poems of P., with a Biographical and Critical Introduction* (Lond. 1866).

Petra ('rock,' the Greek equivalent of the Hebrew *Sela*, properly *Sela*, 2 Kings xiv. 7, cf. Judges i. 36; 2 Chron. xxv. 12; Obad. 3), the ruins of which are found about 70 miles N. by E. of Akaba, in the midst of Mount Seir (Jos. *Ant.* iv. 4, 7), appears to have been the principal stronghold of the Edomites (q. v.) at the time when the latter were conquered by Amaziah (B.C. 837-809) King of Judah (2 Kings xiv. 7). The Israelites gave to the city the name of Joktheel, but it was still called *Sela* in the time of Isaiah (xvi. 1). In the 4th c. B.C., now under the name of P., it was the capital of the Nabatheans (q. v.), who had taken possession of the territory of the Edomites, and who were twice unsuccessfully attacked (about 312 B.C.) by Antigonus, one of the successors of Alexander the Great. At this period P. was the great emporium of the trade between the East and the West, and from the description given by Strabo, Diodorus Siculus, and Pliny, and from the appearance of its ruins at the present day, it was a city lying in a hollow in the bosom of a mountain, and surrounded by precipitous cliffs. The only approach was by a narrow ravine, the bed of a stream which flowed through the midst of the city. The area of the hollow, which was about a mile long and half a mile wide, was occupied by many public buildings, the ruins of which prove them to have been of great extent and magnificence, and private dwellings. There were also bridges over the stream, and a splendid triumphal arch. But as this area was very limited, in seeking to make the most of the site, which was of priceless value as a protection in those times of constant warfare and plundering, the inhabitants excavated the face of the rocks enclosing the area itself, and the sides of the ravines which branch out in all directions, forming habitations, temples, and tombs. It is probable that the first beginnings of the city were made by some wandering tribe taking possession of the natural caves in the limestone rock, which suggested the making of others artificially. But at any rate it has been calculated that, were all the excavations thus formed ranged in regular order, they would form a street five or six miles long. Besides, in some places they are in several 'storeys,' and sometimes 300 or

400 feet above the level of the valley. The fronts of many of them were enriched with a variety of architectural ornaments, and temples were constructed in this way, with their columns and even statuary sculptured out of the solid rock; so that the remarkable contrast was presented of precipices, which towered in natural grandeur to the height of 600 or 700 feet, having their bases wrought into splendid piles of architecture, rivalling in symmetry and beauty the finest monuments of Grecian art; the effect being still further heightened by the brilliant colours of the rock—red, purple, yellow, blue, black, and white. In the 1st c. B.C. P. was the capital of the kingdom of Arabia, to which it gave the name of Petra. Being annexed to the Roman Empire on the overthrow of that kingdom (105 A.D.), its commercial prosperity soon began to decline, although the Emperor Hadrian (A.D. 117-138) conferred certain privileges on it, for which the inhabitants gave his name to their city. The last mention of P. is in 536, the date of a council at Jerusalem at which its bishop was present. The ruins in the Wady Musa, near Mount Hor, were first identified as P. by the traveller Burckhardt, 1812. See his *Travels in Syria, &c.* (1822); Robinson's *Bibl. Researches* (2d ed. 1856). Laborde's *Voyage de l'Arabie Pétrée*, Porter's *Handbook for Syria and Palestine* (1874).

Petrarca, Francesco (baptized **Francesco di Petrarca**), was born at Arezzo, in Tuscany, July 20, 1304. The principal facts of his earlier life we have from himself in the *Epistle to Posterity*. His father, banished from Florence with Dante and other Ghibellines, settled first at Pisa, and then at Avignon, the seat of the Papal court. On the winding banks of the Rhone, or sometimes a little way off at Carpentras, the son learnt 'a smattering of grammar, and as much of dialectics and rhetoric as the age could afford.' Seven years he gave to the study of law at Montpellier and Bologna—seven years, 'not spent, but lost.' At the age of twenty-two he returned to Avignon, where he tells us his acquaintance was already sought by men of eminence, particularly by his staunch and powerful friends, the Colonnas. What were P.'s means of subsistence then is not known: his father, dying in 1326, left him nothing but a treasured copy of Cicero's works. It was not till 1330 that he took up his abode in the palace of Cardinal Colonna. The future poet and scholar, as one of his letters to a brother reveals, was at this time a great dandy; but he was also the most refined and learned man in Avignon. It was this dandy, in his pointed shoes, with frizzled hair, and perfumed cloak, who was transformed into a great poet in the church of the nuns of St. Clara. There, in the Holy Passion week, 1327, he cast eyes on Ugo de Sade's wife, Laura de Noves, a mere girl of twenty, and very beautiful. Beatrice may have occasionally glanced in love on her devoted Dante, but we have no mention of the faintest encouragement accorded to P. by Laura. Speculation regarding her has been baffled: we only know that she lived a virtuous wife to a somewhat exacting husband, to whom she bore a large family. Therefore in the story of Laura and Petrarch there is no tragedy; all is ideal romance, founded on the slightest pretext. The dropping of her glove, the fitting of her shadow, or the rustle of her robe would be theme enough for the finest of his sonnets. The charm of the *Canzoniere* is the charm of a delicate egotism. But P. here revealed a new love to Europe. He blended the grace of the Romans—Ovid, Catullus, Tibullus, Horace, with the Gothic chivalry developed by the troubadours, and with a mystical glamour of religion. Venus and the Virgin become one in his pages. Thus it is for their art, not for any passion they contain, that the world lavishes worship on the sonnets to Laura. In the *Vita Nuova* we feel the pulse quicken and slacken as Beatrice comes and goes, like sunshine on a cloudy day; but we read P. only for his perfect command of expression, for his skill in making much of nothing. Fertile in combination, he is yet barren in images, the whole of which, though they are repeated in endless variety, could be contained in half a dozen sonnets. Yet the amatory strain of P. began a great era in literature, and has inspired every poet since his time.

After travelling restlessly through France and the Low Countries, returning by Burgundy, the Lyonnais, and Dauphiné, P. buried himself in the delightful solitude of Vaucluse, occasionally making journeys to Avignon or Rome, but principally engaged with the *canzoni* and Latin poems. 'By the source of the Sorgia, the well-known haven of my soul, I was wont to wander solitary at evening, and in the morning the melancholy

ripple of the stream against the bank found me there still.' Meanwhile a projected history of Rome had developed into an epic on the second Punic War, entitled *Africa*. His verses on Laura had opened doors for him everywhere: in 1340 the Roman Senate and the University of Paris simultaneously offered him the laurel; and he set out for the King of Naples with his unfinished *Africa*. The king loaded him with honours, and ordered him to repair to Rome. At Rome, on Easter Day, 1341, he ascended the Capitol, received the crown at the hands of the senator Orso, recited a sonnet on the heroes of Rome, and deposited his laurels on the altar of St. Peter's. He was now for a time the man of the world. 'Love and glory,' he makes St. Augustine say to him, 'are the chains which bind you to earth.' In order to obtain means to support his considerable establishment, he accepted an archdeanery of Parma; and at Parma was finished his Latin *Africa*. Landor affirms that no man ever could read more than 500 lines of it. He was next appointed prior of Migliorino, and employed by the Church in some important political missions. The greater part of the next few years was spent at Vaucluse. In 1352 the poet again stepped into the busy world, accepted a mission to reconcile the republic of Genoa with that of Venice, was next employed by Galeazzo Visconti to dissuade Charles IV. from crossing the Alps, and some time after, in 1360, was sent by the same Visconti to Paris to congratulate King Jean on his recovery of freedom. Then he proceeded to Venice, presented his magnificent library to the republic, and was decreed a palace for its reception. Hither came Boccaccio, driven from Florence by the plague. This plague, also, carried away Laura. Boccaccio introduced to P. Leontius Pilatus, teacher of Greek. A teacher of Greek in these days was a king. P., past sixty, eagerly resumed his studies in this language. He never learnt it; but he was one of the first Italians to attempt it. This is indeed his glory. He lives before our eyes in his sonnets, but he mote truly lives as the father of modern learning. He foresaw a new phase of European culture, and inaugurated it by his example: he was the apostle of humanism, the priest of letters. He lavished his time and money in the collection of manuscripts, transcribed many himself, kept five or six amanuenses to copy others, sending or journeying to distant parts of Europe whenever a literary treasure was heard of. What he accumulated, he examined; what he could not read, he set others to read. Thus, when he received a magnificent *Homer* from Constantinople, he urged Boccaccio to its translation. What marvel that his letters evince such knowledge of history and literature, when we remember that this knowledge was only to be got from obscure, crabbied, faded MSS. It would take long to tell the service P.'s scholarship and scholarly enthusiasm rendered to the world.

To detail P.'s various political movements would be tedious. At Ferrara, when just about to set out for Rome, he was seized with a terrible malady. Carried to Padua, he recovered in the balmy bosom of the Euganean hills. Still he continued his literary work with ever-increasing ardour. The great event of his last days was the reception of Boccaccio's *Decameron*. He got by heart the story of Griseldis, and in the last letter he wrote transmitted a Latin translation of it to Boccaccio. At Arqua, on the 18th of July 1374, he was found dead, with his head resting on an open book—fit ending for a life that had been a dream of scholarship. The stain of his youth was a connection which left him a natural son and daughter, the former of whom he survived.

P.'s Latin works are *Epistolæ Familiares*; *Epistola Varia*; *Epistolæ ad Veteres Illustres*; *Epistolæ Scitiles*; *Epistolæ sine Titulo*; *Secretum* (1342); *De Vita Solitaria* (1346); *De Otio Religiosorum* (1347); *Rerum Memorandarum Libri IV.*; *De Vera Sapientia*; *Itinerarium Syriacum*; *De Remediis utriusque Fortune* (1358); *De Officio et Virtutibus Imperatoris*; *Vitarum Virorum Illustrium Epitome*; *De Republica optime Administrationis*; *De sui ipsius et aliorum Ignorantia* (1368); *Epistola ad Posteritatem* (1370); *Apologia contra calumnias Gallorum* (1372); *De Contemptu Mundi*; *De Obedientia ac Fide Uxoribus* (Boccaccio's tale). The standard edition of P.'s Letters is that by Signor Fracassetti (Flor. 1859; Ital. trans. 1863). The Latin poems are *Africa*, *Epistolæ*, and *Eclogæ*. There have been more than 300 editions of P.'s works. The *Canzoniere*, or *Rime del P.* (consisting of *Trionfo d'Amore*, *Trionfo della Castità*, *Trionfo della Morte*, *Trionfo della Fama*, *Trionfo del Tempo*, *Trionfo della Divinità*) was first printed at Venice, 1470. The best modern editions are those of Marsand (Padua,

1819-20) and Leopardi (Milan, 1826). The best edition of P.'s complete works was printed at Basel (1581). The great biography of P. is that of the Abbé de Sade, a descendant of Laura, who wrote *Mémoires pour la Vie de Pétrarque* (3 vols. quarto, Amst. 1764). From this are extracted the English lives by Mrs. Dobson and Thomas Campbell. See also Ugo Foscolo's excellent *Essays on Petrarch* (1823); *Pétrarque; Etude après des nouveaux Documents*, by Mézières (Par. 1857); *Petrarka*, by Geiger (Leips. 1874); and *Petrarch*, by Reeve, in *Modern Classics for English Readers* (1878). The bibliography of P.'s works is to be found in Rossetti's *Raccolta di edizioni di tutti le Opere del P.* (Ven. 1822). Incomplete English translations from Petrarch's poems have been made by Boyd, Nott, Macgregor, Milman, Merivale, Wrangham, and Lady Dacre.

Petre, a Catholic family, descended from Sir William P., 'the silent man,' who was Secretary of State under four reigns, and died in 1572. His only son, Sir John P., was raised to the peerage as Baron P. of Writtle, in Essex, July 21, 1603. William, the fourth baron, on Oates's discovery of the 'Popish plot' (1678), was sent to the Tower, where he died, January 5, 1683. His kinsman, Edward P., the famous Jesuit (born 1631), shared his captivity, but was released on the accession of James II., and called to the Privy Council (1687). Hated and threatened by the populace as James's evil genius, he escaped at the Revolution to the Continent, was rector of St. Omer (1693-97), and died at Watten, May 15, 1699. Another ecclesiastic, Francis P., consecrated bishop *in partibus* (1750), and appointed Vicar Apostolic of the northern district of England, died December 24, 1775. The present head of the family, William Bernard P., was born December 20, 1817, and succeeded as twelfth baron, July 3, 1850. In the Catholic controversy of 1874 he upheld the Vatican Decrees against his brother Henry and Lords Acton and Camoys.

Petrel, the name of various species of *Natatorial* or swimming birds. The best known is the stormy P. (*Thalasidroma pelagica*), or 'Mother Carey's Chicken,' a bird met with far out at sea, and frequently seen riding on the waves in the most stormy weather. It hovers above the surface of the sea, and just contrives to keep itself on the surface through the pattering action of its webbed feet and the flapping of its wings. Its colour is a dull black, and it attains a length of 6 inches. The tail is forked, the legs slender, and the second quill is the longest. Its food consists of

Petrel.

oceanic molluscs and crustaceans. The P. lays a single egg in some disused rabbit burrow. The flesh is very oily. The genus *Procellaria* includes the Fulmar P. (*P. glacialis*), which is plentiful in the northern islands, and attains a length of 20 inches. The colour is a pure white. The eggs of the Fulmar P. are much valued by the inhabitants of St. Kilda and other islands, while an oil is obtained from both old and young birds. Other species are the capped P. (*P. hesitata*), and to the genus *Thalasidroma* belong Wilson's P. (*T. Wilsoni*), the fork-tailed P. (*T. Leachii*), and other species.

Petrification, a general name for anything organic which has been converted into stone. It is almost synonymous with the much more common word *fossil*.

Petrogale, a genus of Kangaroo (q. v.), popularly including the species named rock kangaroos. Of this genus the *P. penicillata* is the most familiar. Its length is about 4 feet, the tail measuring 23 inches. The colour is a purple grey, which is light on the under parts. The P. has no canine teeth, the muzzle is bald, and the tail is tufted at its tip. It is a native of the N.W. of Australia.

Petroica, a genus of Australian birds, of the order *Insectores* and family *Sylviade*. *P. multicolor* is the native 'robin.' The male is of a black colour on the head and back, the forehead being white, and the breast scarlet. The female is brown.

Petroleum ('rock oil'), comprises a series of more or less fluid native hydrocarbons which of late years have taken an important position in the industrial arts. The term covers liquids as thin and mobile as tar naphtha, ranging to others as thick as treacle, in colour varying from almost perfect transparency, with only the slightest straw tinge, up to opaque brownish-black, and in specific gravity from 0.800 to 0.900 or thereby. The more limpid varieties of P. contain little or no paraffin, while the thicker kinds, such as Rangoon P., are of a buttery consistence owing to the large amount of that substance in their constitution. P. is found in some localities oozing out of the earth in the form of natural springs, sometimes by boring it rises to the surface like artesian wells, and in other cases it must be pumped from its subterranean reservoir. P. occurs in very many localities throughout the world; but the sources of greatest commercial importance are certain parts of the shores and islands of the Caspian Sea, the neighbourhood of Rangoon in Burmah, and especially in extensive tracts of country in the United States and Canada. The P. of Rangoon and the Caspian regions is an important source of Paraffin (q. v.).

The important P.-yielding region of America extends from the western counties of Ontario, Canada, southwards to the valley of the Kanawha in W. Virginia. The most productive tracts occur in the N.W. parts of Pennsylvania, but in Ohio and the extreme W. of New York State there are also very valuable wells. The existence of P. in several of these localities has been known since an early period, but it is only since 1859 that American P. has been worked and introduced into commerce; but the traffic rapidly attained enormous proportions, and became a source of vast wealth to many who 'struck it.' In 1875 the P. produced by the 10,499 wells of Pennsylvania amounted to 76,326,733 barrels, the total value of which at the wells was \$245,904,880.

Authorities are not agreed as to the origin of P., but the prevailing opinion is that it has resulted from a natural distillation proceeding within the bowels of the earth, in a manner analogous to that by which paraffin oils are distilled from carbonaceous shales. American geologists consider that the P. of their continent results from the subterranean dry distillation of accumulations of marine plants and animals. In connection with the origin of P., it is worthy of remark that in very many instances the oil springs occur in localities where there are extensive deposits of rock salt.

All crude petroleums consist of mixtures of oils varying in specific gravity and boiling-point; and as the lighter oils give off vapours which, mixed with atmospheric oil, inflame with explosive violence, legislative measures have been adopted in most countries to secure the public from danger of such explosions. The exportation of crude P. from America is prohibited, and in the United Kingdom no burning oil may be sold which evolves inflammable vapours at or under a temperature of 100° Fahr. P. is consequently always submitted to fractional distillation, and the series of commercial oils prepared are brought into commerce under a great variety of names, and consequently, much confusion exists regarding the technology of the substances. The P. is, however, fractioned into three classes of products, 1st, The light oils, which, inflaming at 100°, are not available for illuminating. These are known as benzoline, P. ether, spirit or Rhigolin, and are used for cleaning gloves, freeing clothing from oil stains, &c., for carburetting ordinary illuminating gas, and as an external anæsthetic in neuralgia, &c. 2d, Refined P. or burning oil, which constitutes the larger proportion of what is retailed as paraffin oil. P. has superseded whale, sperm, and vegetable oils as a lighting oil on account of cheapness, brilliancy, and freedom from smoke. In addition to its enormous consumption as an illuminator, it is also used as a solvent for varnishes, &c. The 3d series—the 'heavy' oils—are employed as lubricants under such names as globe oil, vulcan oil, phoenix oil, &c. P. has been used with some success as fuel on board of American steamers, and in the Russian navy, but it is dearer than coal; many efforts have been made to introduce it as fuel both for steam boilers and in metallurgical operations.

The imports of P., derived almost wholly from the United States and Canada, into the United Kingdom during the year 1876 were as follows:—Crude P., 1886 tons, valued at £15,952; refined P., 24,725,905 gallons, valued at £1,415,334; and evidence that the British P. industry continues to expand is afforded

by the fact that the aggregate value of the P. imported during 1877 is returned at £1,772,239. See Huguenet, *Asphaltes et Naphtes* (Par. 1852); Greville Williams, *P. (Philosoph. Trans. 1857)*; Hunt, *Hist. of P. or Rock Oil* (1861); Norman Tate, *P. and its Products* (1863); Buchner, *Mineraloel* (1864); Stoppani, *I Petroli in Italia* (1866); Colin, *Notice sur l'Eclairage aux Huiles Min.* (Par. 1870); Report of Select Com. of House of Lords on P. Bill (1872); Albrecht, *Das Paraffin und die Mineraloel* (Stuttg. 1874).

Law Regarding P. in Great Britain.—The P. Act, 34 and 35 Vict. c. 105, consolidates and amends the laws relating to petroleum. Seven days after importation, and during transit, the vessel in which it is must be labelled conspicuously with a description of the petroleum, adding the words 'highly inflammable.' Licence to keep large quantities of the article must be had from local authorities. Vessels holding not more than a pint, securely stopt, may be kept without licence, provided the whole quantity kept does not exceed three gallons.

Petrol'ogy (Gr. 'science of rocks') is the section of geology which treats solely of the physical properties of rocks, their composition, structure, &c., without any regard to their fossil contents or age. A full and thorough knowledge of mineralogy is necessary to the professional petrologist.

Petromyzon. See LAMPREY.

Petronel (Old Fr. *poitrinel*), a portable firearm introduced into European warfare for cavalry service late in the 14th c. It was a kind of small cannon mounted on a heavy and broad wooden stock, the butt of which was placed against the chest (Fr. *poitrine*, Lat. *pectorina*, from *pectus*) in firing. In the 16th c. the P. resembled a long pistol with a broad butt. It fell into disuse in the following century.

Petronius Arbiter, T., a *littérateur* and voluptuary of the 1st c., author of a work entitled *Satyricon*, in which all sorts of adventures are related. This singular book is written in prose narrative, with occasional pieces in verse, and resembles in its general composition the old Varroian or Menippean satire. Originally it consisted of about twenty books. The MSS., however, have come down to us in a very mutilated state. The oldest of them is a fragment, or rather series of fragments; the connection of which is ever and anon broken by blanks. The very character of the work is altogether uncommon. It is a sort of comic romance, in which a certain Encolpius and his companions in Southern Italy expose false taste in all literary and artistic matters, while they ridicule the folly, lust, luxury, and dishonesty of all around them. The characters are drawn boldly and by the hand of a master. Every line is charged with wit and humour. The Supper of Trimalchio, a rich, uneducated citizen, ever affecting the gentleman, is one of the longest and best things in the work. The minuteness of the delineation of the vices of the period is a serious drawback to a study of this quaint and curious but withal singularly able and accomplished author, the coarseness and obscenity of whose conceptions reveal a fearful state of moral depravity, while the general tone of the writer indicates an evident relish for the scenes which he describes. The *editio princeps* of the fragments of P. was printed at Venice in 1499, the second at Leipsic in 1500. The best editions are those of Burmann (Utrecht, 1709; enlarged Amst. 1743); Antonius (Leips. 1781); and of Bücheler (Berl. 1862), the first really critical edition, and the only one to which, in the present state of criticism on the subject, the student can with confidence be recommended.

Petronius C. (Tacitus), T. (*Pliny* and *Plutarch*), an accomplished voluptuary at the court of Nero—the Beau Brummell of the time—whose skill in the direction of the imperial pleasures secured for him the title of *Elegantius Arbiter*. This expression has led to the common opinion that the person spoken of and P. A. are one and the same. For such a supposition there seems to be no ground whatever. When Tacitus uses the phrase it is merely to describe the individual. 'Arbiter,' in the case in question, is not a name. Another statement on which great weight has been set is that of Pliny, that P. in his last moments despatched a sealed document to Nero, taunting him with his crimes and excesses. But a letter is not a book; and it would be absurd to think that this document was the *Satyricon*. There is, however, a singular likeness in the two persons. P. was no vulgar debauchee; he was a refined voluptuary. At one period of his life at least he gave evidence of fitness for higher things.

He was Proconsul of Bithynia and subsequently Consul, and we learn that he discharged his official duties with energy and ability. Relapsing, however, into a life of luxury and ease, he became prime favourite at the court of Nero. But Tigellinus, another of the Emperor's minions, falsely accused P., who, seeing his destruction certain, committed suicide, 66 A.D. He caused his veins to be opened, and had them closed from time to time, so that his death seemed to be the result of natural and gradual decay. P. is generally supposed to have belonged to the equestrian order, but the statement of Tacitus seems to lead to an opposite inference.

Petropaulovsk ('Peter and Paul's town').—(1) A town of Russia, government of Tobolsk, on the Ischim, 220 miles S.S.W. of Tobolsk, on the great military road through the Kirghiz to Turkestan. It is well fortified, and is the centre of trade between Russia and Central Asia. Pop. (1870) 9000. (2) A town on the E. coast of the peninsula of Kamtchatka, at the head of Awatscha Bay. It is 8740 miles from St. Petersburg, and from P. to Taurigen near Tilsit is 9200 miles, the greatest distance between two places in the Russian Empire. Formerly a place of considerable commerce, its importance sank as that of the Amur district rose, and the population has diminished to 600. P. received its name from the two ships, the Peter and Paul, of the navigator Behring, to whom a monument is erected here. The fortifications were razed in 1855, during the Crimean War, by the English and French.

Petrosavodsk, chief town of the government of Olonetz, Russia, on the W. bank of Lake Onega, 282 miles N.E. of St. Petersburg. It was founded 1703, is the seat of an archbishop, and has important iron foundries, of which the Alexandrovsky arms factory is the chief. It has already produced more than 30,000 pieces of ordnance. Pop. (1870) 10,900.

Petsh'a (*Pescium*), or **Ipék** (i.e., 'silk'), a town of European Turkey, vilayet of Prisen, on the Bistritza, 50 miles W. of Prishtina. The former residence of the Servian patriarchy, it is a pleasant place, embowered in orchards and mulberry groves, and producing silk, tobacco, and fruits. Pop. 16,600.

Pettichaps, the name applied to several kinds of Warblers (q. v.) or *Insessorial* birds of the sub-family *Luscinia*. The greater P. is the Garden White-throat (*Sylvia hortensis*), a bird attaining a length of 6 inches, of a brown colour above and white below, the throat being pale brown. Its song is very melodious. The lesser P. (*Sylvia rufa*) is otherwise named the 'Chiff-Chaff' from its cry. It is ashen brown above, and white, tinted with light brown, beneath. Its length is 5 inches. These birds are migratory. The lesser P. arrives in Britain in March and April, and leaves in October.

Pettie, John, R.A., born in 1839 at Edinburgh, studied at the Royal Academy classes there from 1855 till 1862, and in the latter year removed to London, where he has won a brilliant reputation for vigour, variety, and resource in art. He was elected Associate of the Royal Academy in 1866, and Royal Academician in 1873. Of his numerous works, which are chiefly historical or higher *genre*, it is impossible to mention more than a few of the more prominent, as 'What d'ye lack, Madam?' (1861), 'The Trio' (1863), 'The Rival Roses' (1871), 'The State Secret,' 'Jehet and Friar Lawrence' (1874), 'The Sword and Dagger Fight' (1877), and 'Disbanded' (1878). His painting is remarkable for character, force, and technical dexterity, and in portraiture he occupies a high place.

Petty, Sir William, the earliest English economist, was born at Romsey, in Hampshire, May 16, 1623, and was educated at the grammar school of his native town, and at Caen in Normandy. After serving for a short time in the navy, he studied medicine for three years at Leyden, Utrecht, and Paris, and returning to England (1646), obtained a patent for his 'pantagraph' or copying-machine. He came to Oxford (1648), became a fellow of Brasenose (1649) and anatomical professor (1650), and was one of the earliest members of the Royal Society. Appointed physician to the army in Ireland (1652), he obtained the surveyorship of the forfeited Irish estates (1654), a post which brought him in £10,000, and afterwards became secretary to Henry Cromwell and member for West Looe (1658). At the Restoration he was knighted and created surveyor-general of Ireland, where he did much to promote the mining, timber, and fishing industries, whilst at London he was one of the chief

revivers of the Royal Society. He died at Westminster, 16th December 1687, leaving two sons, the second of whom was the ancestor of the Lansdowne family (see LANSDOWNE). Besides his valuable treatises on population, P. wrote *Taxes and Contributions* (1662), the financial *Quantulumcumque* (1682), *The Political Anatomy of Ireland* (1692), &c.; and he was the inventor of a double-bottomed ship, which was to sail against wind and tide, but came to an untimely end whilst crossing the Irish Channel.

Petty Officers, a class of sailors in the royal navy having duties and responsibilities akin to those of non-commissioned officers in the army. There are three classes of P. O., with daily pay varying from 6s. to 2s.,—the chief P. O. including the master-at-arms, the chief gunner's mate, the chief boatswain's mate, the chief captain of the fore-castle, the admiral's coxswain, the chief quartermaster, chief carpenter's mate, &c.; the first class working P. O. including the ship's corporal, gunner's and boatswain's mates, the captain of the fore-castle, the captain's coxswain, the quartermaster, coxswain of the launch, captains of the maintop, foretop, &c.; the sailmaker and principal artificers; and the second class working P. O. consisting of a lower grade of responsible seamen and artificers.

Petty Sessions. The sitting of Justices of the Peace in court is called *Sessions*. They have power, under statutes, to make divisions of counties for sessional and magisterial purposes, each justice, except during Quarter Sessions (q. v.), usually exercising his jurisdiction only in the division in which he is resident. But justices have generally stated places and times of meeting for the despatch of such business as requires by law the presence of more than one justice, and yet does not require to be brought before Quarter Sessions, or Special Sessions (q. v.). These meetings are called P. S.

Petu'nia, a genus of S. American *Solanaceæ* closely related to the tobacco, but of no economic service. They have sticky leaves, axillary funnel-shaped flowers, generally white or some shade of purple, but the gardener's skill has now introduced varieties with striped and with double corollas—and are much used for bedding-out purposes. Some of them are sweet-smelling.

Petunt'ze, a white felspathic earth used by the Chinese in the manufacture of porcelain. By fusion it gives to the kaolin a glazed appearance.

Pet'worth, or **Sussex Marble**, a various coloured limestone, occurring as a thin layer in the Weald clay, and composed of the shells of fresh-water *Paludina*. In the cathedrals of Chichester and Canterbury there are pillars formed of it, and it is otherwise used for ornamental purposes.

Peuting'er, Konrad, a celebrated German antiquary, was born at Augsburg, 14th October 1465. After an education at Padua, Bologna, Florence, and Rome, he returned to Germany about 1486, and became town-clerk of his native city about 1493. After his death (24th December 1547) his valuable library fell to his own family, afterwards, however, to the Jesuits at Augsburg. P. wrote several works on antiquities, chief of which were *Romane Velutatis fragmenta in Augustana Vindelicorum* (Augsb. 1505), and *Sermones Convivales de mirandis Germanie Antiquitatibus* (*Ibid.* 1506). He discovered in a Benedictine monastery at Tegernsee the so-called *Tabula Peuting'eriana*, a map of the military roads of the West Roman Empire, dating from the 4th c. A part of it was published by Marcus Welser as *Fragmenta Tabule Antiquæ ex Peuting'erorum Bibliotheca* (Venice, 1591). From this date the map was mislaid till 1714, when, being discovered among P.'s MSS., it was sold to a bookseller, from whom it was bought by Prince Eugene, who presented it to the Vienna Library. Complete editions have been published by Franz Christoph von Scheyb (Vien. 1753), by Mannert (12 vols. Leips. 1824), who gives a complete account of its fortunes from the 4th to the 19th c., and by D'Urban in his *Récueil d'Itinéraires Anciens* (Par. 1845).

Pew (Old Fr. *puy*, Lat. *podium*, 'a support'), a term originally applied to the low open benches introduced into English churches as early at least as the 13th c. The ends of these were often richly carved, terminating in a poppy-head or other finial. After the Reformation, and under Puritan influences, they were generally replaced by the high hideous enclosures familiarly

known as 'horse-boxes,' which in this present age of church restoration are happily making way for benches of the ancient form or for chairs. In England, says Blackstone, 'pews may descend by custom immemorial (without any ecclesiastical concurrence) from the ancestor to the heir;' they may also be held by a special faculty from the ordinary, or they may be assigned by the churchwardens to the parishioners according to their degree. In Scotland their assignation is vested in the heritors; in the United States different customs prevail in different States, pews being sometimes in the entire custody of the vestry or trustees, sometimes leased for a limited period, and frequently conveyed in a perpetual lease with an annual rent. Of late years a strong feeling has arisen that all seats in a church should be free and unreserved, and in many town churches of England a voluntary offertory has been established in lieu of the income formerly derived from pew-rents.

Pew'ter (Old Fr. *peutre*, Low Lat. *pentrum*), ordinarily an alloy of tin with antimony and lead, though the best P. has copper added in place of lead. Common P. contains only tin and lead in the proportion of 4 : 1. A fine P. is obtained by fusing together 100 parts of tin, 8 of antimony, 1 of bismuth, and 4 of copper. The effect of these additions is to harden the tin and preserve its colour, so that a good P. keeps its silvery lustre for long untarnished.

Peyer's Glands, an important group of Glands (q. v.), occurring chiefly in the small intestine, and which appear to be specially affected in typhoid fever. They are most abundant at the terminal part of the *ileum*, near the *ileo-cæcal valve*. These glands are met with in two forms, *solitary* and *agminated*, the latter being also known as *P.'s patches*. The patches vary from 1 to 3 inches in length, and attain a width of about half an inch. They are of oval form. Each gland is from half a line to a line in diameter, and consists of a network of fine fibres containing lymphoid corpuscles. The glands are penetrated by blood-vessels and surrounded with lymphatic vessels. Their functions would appear to be that of absorbing certain materials from the *chyle* or digested food. P. G. are largest in the young, and disappear in adult life.

Pézénas, a town of France, department of Hérault, on the river Peyne, at a short distance from its junction with the Hérault. It has manufactures of iron, copper, and chemicals, and a large trade in grain, wine, and liqueurs. Pop. (1872) 7314.

Pfäfers, less correctly **Pfeff'ers**, a village in the Swiss canton of St. Gall, 5 miles S.S.E. of Sargans. Its hot medicinal baths have been famous since 1038. They are situated in the deep rocky valley of the Tamina, 2259 feet above the sea, and the access to them is between walls of rock from 533 to 853 feet high. The water of the main spring has a temperature of 85.4° F., that of the lower 100.6° F. In 1860 a drain 85 feet long was made through the rocks to a large grotto, into which flow 16 to 20,000 quarts of water per minute. At the village a rich Benedictine abbey (suppressed 1838) has been converted into a lunatic asylum, St. Perminenberg. Pop. 1540.

Pfeiffer, Ida (*née Beyer*), born at Vienna, 15th October 1797, showed from early youth great energy and love of knowledge. After being separated from her husband, and having completed the education of her two sons, she resolved to travel abroad. She first went to Palestine in 1842, and the account of her journey, *Reise einer Wienerin in das Heilige Land* (2 vols. Vien. 1843; 4th ed. 1856), being favourably received, she next visited (1845) the three Scandinavian kingdoms and Iceland (*Reise nach dem Skandinavischen Norden*, 2 vols. Pesth, 1846), and proceeded to S. America, Australia, India, Persia, and Asia Minor; thereafter publishing *Eine Frauenfahrt um die Welt* (3 vols. Vien. 1850), a work rich in observations on woman's home life in the countries where she had been. In March 1851 she undertook a new journey. Going first to England, she left that country in May for Australasia, where she remained a year and a half on the Sunda Isles, and boldly penetrated to the interior of Sumatra and Borneo. She then proceeded to the west part of S. America, and from thence travelled through N. America, and reached home in May 1855. *Meine zweite Weltreise* appeared in 4 vols. in 1856. In the spring of the latter year she went to Madagascar, was there cast into prison and hardly treated by the natives, and did not regain her liberty till 1858, when she returned home to die (28th October) of the ill-

usage she had received. The account of her latest travels, *Reise nach Madagascari*, contains also a biography of P. (2 vols. Vien. 1861). See *Du Reisende Ida P. in Unsere Zeit* (2 vols. Leipzig, 1855).

Pforzheim, an industrial town of Germany, in the Grand Duchy of Baden, at the confluence of the Enz, the Wurm, and the Nagold, on the N. skirt of the Schwarzwald, 35 miles S.S.E. of Mannheim by rail. Long the residence of the Markgraves of the extinct Baden-Durlach-Ernestine line, it has an ancient castle, and on an eminence a *schloss kirche*, erected between the 12th and 15th centuries, containing many interesting statues and memorials. The staple products are gold and silver wares, the production of which employs 7000 men. P also manufactures chemicals, iron machinery, ultramarine paper, &c., and carries on a trade in timber, oil, and wine. Pop (1875) 23,537.

Phædrus, a Latin fabulist of the Augustan period, was probably at one time a slave of the Emperor, as the title of his work indicates—*Phædrus Aug. Liberti Fabule Fæopæ*—and it is said he came from Thrace or Macedonia. His fables were principally translations of *Æsop's*, and their excellence was proportional to the closeness of the paraphrase. His only merit is a beautiful style. Another collection of thirty-two fables—*Eptome Fabularum*—first published at Naples, 1809, has been connected with his name by some. The standard edition of his writings is that of Orelli (Zurich 1831). Another edition is that of Muller (Leips. 1876).

Phæthon (Gr. 'glittering'), originally an epithet of the sun, came next to be the name of one of the sun god's horses, and finally of the son of Helios and Clymene, a daring youth, who, essaying to guide his father's chariot, drove so near the earth as almost to set it on fire. Thereupon Zeus slew him with a thunderbolt, and cast his body into the Eridanus or Po, whilst his weeping sisters, the Heliades, were changed into the amber-dropping poplars that fringed its banks—*Phæton*, an open pleasure carriage on four wheels, takes its name from this mythic charioteer.

Phagedæna (Gr. *phagen*, 'to eat,' or 'corrode') is the term applied to a combination of ulceration and gangrene, in which the ulcer, as it spreads, sloughs more or less deeply. There are two forms of this affection, viz., spreading P, and sloughing P. In spreading P, ulceration is the prominent symptom, the sloughing being only superficial, but in sloughing P, the slough is the prominent symptom, the surface of the ulcer being thick, black, and round in shape, a considerable depth of tissue being involved. Underneath the superficial slough, ulceration generally proceeds rapidly, involving destruction of the tissues. There is usually a yellowish green or brownish foetid discharge, and occasionally bleeding from destruction of the vessels. The pain is of a severe, burning, stinging, and lancinating character. There is also a severe form of *non-healing* P, usually called 'hospital gangrene,' which is infectious or contagious, and epidemic in its nature. P is frequently the result of tuberculosis, the syphilitic virus, intemperance, and the abuse of mercury. Hospital gangrene usually originates and spreads in hospitals where there is much overcrowding, and where the hygienic conditions are unfavourable.

Phalanger, a genus of *Marsupial* quadrupeds, also named *phalangists*, and represented by the Sooty P (*Phalanger fuliginosa*), the P. vulpine or vulpine P, and other species. The vulpine P. is sometimes named the Australian Opossum, although it does not belong to the family of the true or American Opossum (q. v.). In the P, the second and third toes of the hinder feet are united by the integument nearly to their extremities. The great toe may be opposed to the others, and is devoid of a nail, while the rest have long curved claws. The tail is long, and its tip is prehensile. The animal is nocturnal in habits, and lives chiefly in trees and on vegetable food. The canine teeth are small. The vulpine P. attains a length of 2 feet and even more.

Phalangides, a family of *Arachnida* (q. v.), represented by the so-called 'harvest spiders.' The legs are extremely long, and the *maxillary palpi* are filamentous organs, and are terminated by claws of a simple kind. These Arachnidans receive their popular name from appearing in the fields in great numbers after harvest.

Phalanx (Gr. probably akin to *phallos*; cf. Eng. *column*), in the tactics of the ancients, a battalion of heavy infantry (*hoplites*), drawn up close and deep, and armed with spears 21 feet long, and short swords. Such a formation was known to Homer, and was effectively employed at Marathon (480 B.C.). It was reorganised by Philip (359 B.C.), the Macedonian P comprising 16,384 men, sixteen deep, who were drawn up so that the spears of the fifth rank projected 3 feet beyond the first. This huge body, which could only act on level and open ground, was necessarily slow in its movements, and once broken fell an easy prey to the enemy. Hence the P. was from the first over-matched, and in course of time superseded, by the Roman Legion (q. v.).

Phalanx, the name given to each of the joints or small bones of which the digits of vertebrates are composed. Three *phalanges* exist in each digit of man, with the exception of the great toe and thumb, in which only two are found. In some mammals (and particularly in Cetacea) the number of P is very great.

Phalaris, a tyrant of Agrigentum, in Sicily, who maintained himself on the throne for sixteen years (565-549 B.C.) with the aid of mercenaries and by the execution of the leading citizens. He roasted them alive in a brazen bull, making the first experiment on its inventor, Perillus. The so-called *Letters of P.* (Ven. 1498) were conclusively shown to be spurious by Bentley (q. v.), who styles them 'a fardle of commonplaces.' Their exact date cannot be determined, but they certainly belong to the Christian era.

Phalarope (*Phalaropus*), a genus of *Grallatorial* or Wading birds (represented by the grey P (*P. fulicarius*), by the red-necked P (*P. hypoboreus*), and by other species. It is allied to the Snipe (q. v.). The genus P. has a long bill, and has the first and second quills longest. The toes are united at the base, and have lobes at the sides, and the hinder toe is raised and edged with a narrow membrane. The grey P. is an Arctic bird, which visits Britain in autumn and winter. It is agile in flight, and a dextrous swimmer, feeding on crustacea and molluscs. The winter plumage is blackish brown on the head, neck, and back, a white band exists on the wing, and the neck and under part are of a dull red. The breast and belly are pure white. The average length is 8 inches. The red-necked P. is smaller than the grey species.

Phallus (Gr. akin to Sansk. *pal*, 'to produce'), the Greek symbol of the generative power of nature, corresponding to the Semitic *Asherah* and the *Ingir* (q. v.) of the natives of India. It was usually made of fig-wood, and was borne in procession at the Dionysiac festivals.

Phallus, a genus of *Gasteromycetous* fungi in which the stem arises from a gelatinous volva, and is surmounted by a slightly wrinkled or deeply pitted conical pilius perforated at the apex. The growth is very rapid, as is also the decay, the hymenium with the spores passing into a foetid semifluid mass. Some of the species are beautiful objects, but all have an odorous smell at some period of their existence. The common stinkhorn (*P. impudicus*), a species frequent in Britain in open woods, shrubberies, &c., besides an unsightly appearance, has a disgusting carrion-like odour that may be felt for yards around its place of growth.

Phanerogamous Plants (Gr. *phaneros*, 'visible,' *gamos*, 'union'), a name applied to plants having visible flowers, in contradistinction to the flowerless plants or Cryptogamia (q. v.). The definition might otherwise be expressed by saying that the latter are destitute of flowers containing anthers and ovules, while P. have these organs. They comprise dicotyledons, monocotyledons, and gymnosperms, already referred to under separate headings. Alphonse de Candolle (1873) estimates the number of P. existing in the world up to 120,000 species.

Pharaoh (Heb. *Phar'oh*), the name applied generally to the kings of Egypt in the Old Testament, is sometimes used by itself as a proper name (cf. Gen. xii. 15, &c.), a sense which is more clearly implied when, as is sometimes the case, the title 'king of Egypt' is subjoined to it (cf. 1 Kings iii. 1, &c.); and sometimes the generality of the name, like that of the Roman Cæsar, is implied by the real proper name being added (cf. P. Necho, 2 Kings xiii. 33; P. Hophra, Jer. xlii. 30). The

meaning of the name was given by Josephus (*Ants.* viii. 6, 2) as simply 'king,' but in modern times it has been identified with P-RA or PH-RA, the sun-god of the hieroglyphics, as if this king had been regarded as his representative on earth, and by others with Per-na or Pher-ao, lit. 'high house.'

1. The first P. mentioned in the Bible is the contemporary of Abraham (Gen. xii. 10-20), who is conjectured by Egyptologists to have been Salatis, Saites, or Set, the first king of the 15th (Hyk-shos) dynasty (about B.C. 2080), who held their court at Memphis and afterwards at Tanis (Avaris, Zoan). 2. The contemporary of Joseph (Gen. xl., &c.) has been identified with Usertesen I., the head of the 12th dynasty (Bunsen), but more generally with Apophis or Apepi II. of the 15th (about B.C. 1875). 3. The P. who oppressed the Israelites has been identified with Rameses II. of the 19th dynasty (about B.C. 1400), who, according to the hieroglyphics, built a chain of forts from Pelusium to Heliopolis, of which the two principal ones were called Rameses and Pachtum (Pithom, Exod. i. 11); 4. the P. of the Exodus (q. v.) with his son Memphthah or Amenophis. 5. The question as to who was the P. the father-in-law of Mered (1 Chron. iv. 18) is obscure and unimportant. 6. P., the brother-in-law of Hadad (1 Kings xi. 10-20), is supposed to have been Osochor of the 21st dynasty; 7. the father-in-law of Solomon, his successor Psusennes II. 8. P. the ally of Hezekiah against Sennacherib (Isa. xxxvi. 6), otherwise Tirhakah, king of Ethiopia (2 Kings xix. 9), was Taharka or Tirharka, the third of the 25th (Ethiopian) dynasty (about B.C. 694-668), who is known from the Assyrian cuneiform inscriptions to have waged war against the Assyrian kings Esarhaddon and Assurbannipal. 9. P. Necho, by whom Josiah king of Judah was defeated and slain (2 Kings xxiii. 29; 2 Chron. xxxv. 20-24), was the son of Psammetichus I. of the 26th dynasty. 10. P. Hophra, who raised the siege of Jerusalem conducted by Nebuchadnezzar in the time of Zedekiah (Jer. xxxvii. 5, xlv. 30), was the successor (about B.C. 599) of Psammetichus II., who succeeded Necho.

Pharisees were one of the so-called religious sects among the Jews in the time of Christ. The name (Gr. *phariseos*, Heb. *pharush*, pl. *pharushim*, 'the separated') denoted those who separated themselves from Levitical impurity, which of course implied separation from those who were defiled by that. They styled themselves the 'Wise' or 'Disciples of the Wise,' and 'Associates,' meaning those who banded themselves together for the purpose of keeping the Mosaic laws regarding purity. As this implied a close study of, and great reverence for, the law, the great majority of the Scribes (q. v.), the learned in the law, belonged to the P. The religious societies of later Judaism are generally called *sects*, and a mistaken notion regarding them prevails in consequence. Sect as thus applied is a translation of the Greek word *hairesis* ('heresy'), used by Josephus in applying the titles of the schools of Greek philosophy to Jewish circumstances. These 'heresies,' however, were not, either among the Greeks or the Jews, sects at all in the modern sense, but schools of thought or parties, with no intention of separating from the general community.

The history of the P. begins with the return of the Jews from Babylon. They appear first as the 'separatists' of the time of Ezra, as opposed to those who held intercourse with the people of the land, and took wives from among them (cf. Ezra vi. 21, ix. 1, 2, x. 11; Neh. ix. 2, x. 29). The natural descendants of these were the Chasidim (q. v.), or Puritans of a somewhat later period. At least from the 3d c. B.C. the executive power was in the hands of the high priest and a council of elders. Before the reign of Antiochus Epiphanes (B.C. 175), from various causes, the common people, with the Scribes at their head, stood opposed to this priestly aristocracy. Under the first Asmoneans the two classes were driven by mutual antagonism into the position of parties, which under Jonathan (B.C. 161-143) became known as the P. and the Sadducees (q. v.). The former, then, were the national party, representing the democratic, religious tendency; the latter were the aristocratic party, representing the moderate, political tendency, which sought foreign alliances, and tried to introduce Gentile manners and customs. Jason (B.C. 175) and Menelaus (B.C. 172) overdid this policy, and thereby destroyed the popularity of the aristocracy; and their power was nearly ruined altogether when the nation revolted under the Maccabees (q. v.). But as the Asmoneans rose in power, becoming first high priests and then princes, a

breach was again formed between the P. and the aristocracy, which resulted in a civil war in the time of Alexander Jannæus (B.C. 103-79). In the time of Herod the Great (B.C. 37-4) the P., who numbered 6000, refused to swear allegiance to the king. But by this time the unity of the party was broken. A party of them, the turbulent spirits, engaged in conspiracies against Herod, while the majority, withdrawing more and more from politics as the condition of the country became more hopeless, sought to console themselves with a more eager study and observance of the law. But while the P. are thus to be regarded as the national party, it follows from the very principle on which their existence as a party was founded, that a large number of the common people could not belong to them, but were in the position of outcasts, namely, all who, as in the time of Ezra, mingled too freely with the heathen in Palestine, which class would include the publicans, the creatures of Rome, and those of immoral life.

As to the general character of the P., the tendency described above inevitably led to the development among them of formalism, self-complacency, ostentation, superstition, and hypocrisy; but it is a great mistake to conclude, as is generally done, from the denunciations of Christ (cf. Mat. xxiii. 13-33; Luke vii. 36-50) that all the P. were self-righteous, superstitious, or hypocritical. The language of the Talmud (q. v.), i.e., of the P. themselves, in denouncing self-righteousness and hypocrisy is quite as strong as that of the New Testament.

From what has been said it will appear that the tenets and practices of the P. are those of orthodox Judaism. The fundamental tenet of the party was that the whole nation were kings and priests, a holy nation, the object of most of their enactments being to make the people realise this—e.g., at their social meals they paid great attention to washing themselves and the vessels they used, intending those meals to be like the meals of the priests. It was in this light, too, that they considered themselves to be the guardians of the law, in connection with which was another of their tenets, 'that by the side of the written law there was an oral law to complete and explain the former,' and which, like the former, was received by Moses from Sinai, and then transmitted by tradition to the men of the Great Synagogue; believing that so long as they remained faithful to God by keeping his law no power on earth could harm them. Hence they utterly repudiated the time-serving policy of the Sadducees, who maintained that human ingenuity and statecraft ought to be resorted to in political matters. The objection to this theory from the calamities of the righteous and the prosperity of the wicked, the P. met with the doctrine of a future life, in which all these irregularities would be rectified. To facilitate obedience to the law, they put a mild interpretation on some of the Mosaic enactments, and tried to adapt them to varying circumstances. Thus, while the Sadducees understood the right of retaliation (Exod. xxi. 23) literally, the P. explained it as requiring a pecuniary compensation. See E. Deutscher on *The Talmud* (*Quart. Rev.*, October 1867, or *Lit. Remains*, Lond. 1874); C. D. Ginsburg in Kittó's *Cyria*, of *Bib. Lit.* (3d ed. Edinb. 1876); Ewald's *Gesch. der Volks Isrl.* (Eng. trans. 2d ed. 1869); Kuenen's *Rel. of Israel* (Eng. trans. 1874-75); Stanley's *Jewish Church* (3d series, 2d ed. Lond. 1877); and Cohen's *Les Pharisiens* (2 vols. Par. 1877).

Pharmacopœia (Gr. *pharmakon*, a 'drug' or 'medicine,' and *poiō*, 'I make') is the term applied to various books of directions for the preparation of medicines, published by the Colleges of Physicians, with the sanction of Government. Such works usually consist of a list of the articles of the *Materia Medica* (q. v.), with their properties, doses, and the tests for the determination of their purity; and also a collection of approved receipts for the treatment of disease. The first P. published under authority was that of Nürnberg, in the year 1542, the collection having been made by a student named Valerius Cordus from the works of the most eminent medical authors. Previous to that date, the works principally used by apothecaries and physicians were the book *On Simples*, by Avicenna and Serapion; the *Liber Serapioris*, by Balchasim bin Aberazerim; the *Antidotarium*, by Johannes Damascenus or Mezue; and the *Antidotarium* by Nicolaus de Salerno, commonly called *Nephtali* *Magnum* to distinguish it from an abridgment known as *Nephtali* *Parvus*.

The first edition of the P. of the London College of Physicians, which appeared in 1618, was chiefly founded on the works

of Mesue and Nicolaus de Salerno; and successive editions appeared in 1627, 1635, 1650, 1697, 1721, 1746, 1787, 1809, 1824, 1836, and 1851. Many of the pharmaceutical preparations enumerated in the earlier editions are of the most extraordinary nature, and indicate the low state of medical science in the 17th and 18th centuries. The skull of a man who had been hanged, the urine and excrements of various animals, the blood of the cat, frogs, toads, puppy dogs, worms, snails, and woodlice find a place in the earlier editions of the P. Medicinal compounds of the most complicated nature, containing sometimes a hundred different ingredients, were ordered; thus, the *Great Antidote against Poison and Pestilence* of Mathiolus contained 124 ingredients.

The first edition of the Edinburgh P. appeared in 1699, and the Dublin in 1809. The right of publishing the pharmacopœias of London, Edinburgh, and Dublin was vested in the Colleges of Physicians of these places respectively; but by the Medical Act of 1858 it was ordained that "the General [Medical] Council shall cause to be published, under their direction, a book containing a list of medicines and compounds, and the manner of preparing them, together with the true weights and measures by which they are to be prepared and mixed; and containing such other matter and things relating thereto as the General Council shall think fit, to be called the *British P.*, which shall for all purposes be deemed to be substituted throughout *Great Britain and Ireland* for the several above-mentioned Pharmacopœias." This clause in the Medical Act was rendered necessary, as each P. contained many important preparations, similar in name but totally different in strength, so that dangerous accidents arose, as from a London prescription being made up in Dublin, or *vice versa*. The first British P., which appeared in 1864, although having the advantage of uniformity, had defects, and gave rise to such a general feeling of disappointment throughout the whole ranks of the medical profession that the Medical Council ordered a new edition to be prepared, the preparation of which was intrusted to a committee of eminent men, with the President of the Medical Council as chairman. These gentlemen were engaged some years upon the work, and, when completed, it was submitted to all the members of the Medical Council, and to other practical men, for the purpose of receiving suggestions. Into this edition (1867) of the P. about 100 medicines were introduced, which had been left out in the first edition, the more important additions being benzoated lard, bromide of ammonium, carbonate of bismuth, solution of citrate of bismuth and ammonia, iodide of cadmium, oxalate of cerium, flexile collodion, glycerines of borax, carbolic acid, gallic acid, tannic acid and starch, compound ointment of mercury, mercury suppositories, medicinal lozenges, tinctures of pyrethrum and sumbul, &c.

The P. Germanica and the United States P. have been recently published, and a reprint of the British P. has been recently issued by the Medical Council, to which an Addendum has been appended. Austria, Belgium, France, and Russia have also their respective pharmacopœias; but a universal P., or one of so general a nature that the most important medicines shall be all of the same strength, is still a desideratum. See the *British P.*, and *Squire's Companion to the British P.* (11th ed. Lond. 1877).

Pharmacy (Gr. *pharmakon*, 'a medicine') is that department of *Materia Medica* (q. v.) which treats of the collection, preparing, preserving, and compounding medicines, and of dispensing them according to the formulæ or prescriptions of medical practitioners. The term P. is sometimes used in a more limited sense to denote the application of the laws of chemistry to medicines so as to render them easy of administration and more perfect and certain in their action. P. is sometimes used to denote the art of compounding and mixing drugs according to the prescription of the physician.

Pharos. See LIGHTHOUSE.

Pharsalus (mod. *Fersala*), anciently a town of Thessalia, 10 miles from the left bank of the Enipeus, and 24 miles S. of Larissa. Near it Cæsar defeated Pompey, August 9, 48 B.C., the former losing from 230 to 1200 men out of 22,000 legionaries and 1000 cavalry; whilst of Pompey's army, composed of 45,000 legionaries and 1000 cavalry, besides a host of light-armed auxiliaries, 6000 were slain and more than 24,000 taken prisoners.

Pharyngean fish ('pharynx-breathers'), the name of the lowest order of fishes, represented by the Lancelet (q. v.) alone.

Pharyngognathi, a group of *Teleostean* (q. v.) fishes represented by the Wrasses (q. v.), and forming a subdivision of the sub-order *Acanthopteri*, including the teleosteans with spiny-fin rays, e.g., perches. The inferior pharyngeal bones in the P. are united so as to form a single bone, on which teeth may be borne.

Pharynx (Gr.), the hinder part of the mouth in man and vertebrata generally. It lies behind the mouth, nose, and larynx, and thus constitutes the upper portion of the alimentary canal proper. The P. consists essentially of a muscular sac, of conical shape, the base being turned upwards or towards the mouth. It may be regarded as extending from the base of the skull to the *cricoid cartilage* of the larynx as a front boundary, and to the fifth cervical vertebra behind. In length it measures 4½ inches. It is attached behind by loose tissue to the spine, while below it merges into the *œsophagus* or gullet. Into the P. no less than seven apertures open—the mouth, the two *Eustachian tubes* (leading from the internal ear), the two posterior *nares* or hinder nostrils, the larynx, and the gullet or *œsophagus*. In structure the P. is seen to be composed of an external or *fibrous coat*, a middle or *muscular coat*, and an internal or *mucous layer*. The last is continuous with that of the mouth, gullet, larynx, and Eustachian tubes, and is covered by columnar *Epithelium* (q. v.) of the *ciliated* variety. The *mucous glands* of the P. are very numerous. In the act of *deglutition* or swallowing the P. is intimately concerned, being raised up towards the back of the tongue to receive the food.

Diseases of the P.—The P. is liable to acute inflammation, or pharyngitis, which is constant in sore throat of all kinds, and which may be propagated from the spine, and by erysipelatous affections spreading inwards. Follicular inflammation of the P., or *clergyman's sore throat*, is indicated by huskiness of the voice, coughing, hawking, and spitting. The follicles of the *isthmus faucium* and of the P. are prominent, the mucous membrane having the appearance of being studded with granulations, and the follicles sometimes burst and discharge small masses. This is occasionally followed by ulceration. The constitutional remedies are iron, quinine, and strychnia, and the most useful topical applications are solutions of nitrate of silver, or of creosote. In cases of diphtheria, the P. is frequently the most important seat of the disease. It is occasionally the seat of tumours, and malformations of the P. and *œsophagus* are not uncommon. Abscesses of the P. may be formed as the result of inflammation, or in connection with disease of the spine.

Phascogale, or **Tapoa Tafa** (*Phascogale pencilata*), a species of *Marsupial* quadrupeds inhabiting Australia, and attaining a length of 17 inches. The colour is grey above and white below, the fur being exceedingly soft and woolly. The tail is very long, and has a tuft of black hairs at its extremity. The P. is a most rapacious creature, doing great damage in hen-houses. It appears to form its burrow or nest in the trunks of trees.

Phascolarctos, a genus of *Marsupial* mammals, represented by the koala or kangaroo bear (*P. cinereus*), also named the 'native sloth' by the Australian colonists. The koala attains a length of 2 feet, and is covered with a bluish-grey fur. The tail is rudimentary, and the claws are strong, and adapt the animal for an arboreal life. The great toe is opposable to the other toes, and the fingers are divided into two sets, so as to constitute a hand-like member capable of grasping the boughs of trees.

Phascolotherium, an extinct genus of mammalia, believed to include species of insectivorous marsupialia. The remains of this genus are among the earliest relics of mammalian life on the globe. They occur in the Stonesfield slates of the Lower Gault. The extinct P. is regarded as being most nearly represented by the existing Opossum.

Phase (Gr. *phasis*, 'an appearance'), in physics, is the particular state, at a given instant, of a continuously varying and periodic phenomenon. Thus we speak of the successive phases of an eclipse, of a tide, &c.

In astronomy, P. is the name given to the appearance of a heavenly body, the visible portion of whose illuminated surface alters with change of position. The phases of the moon are familiar to all, and show that our satellite is not self-luminous, but shines solely by reflected solar light. The planets Mercury, Venus, Mars, and Jupiter show certain similar but less marked

phases. That Venus had this characteristic was shown by Galileo as soon as he directed his telescope towards her; and at the time this discovery was regarded as irresistible argument in favour of the Copernican system of the universe.

Phaseolus. See KIDNEY BEAN.

Phasianidæ. See PHEASANT.

Phasis (mod. *Rion*), the ancient name of a river of Colchis (Mingrelia), which, rising on the southern slope of the Caucasus, at an elevation of 2735 feet, flows eastward to the Black Sea, which it enters at Poti, after a course of 138 miles. With the Cyrus (Kur) and Oxus it formed, and to some extent still forms, a mercantile highway between Greece and Persia. The pheasant (*Avis Phasianus*) was so named because originally brought from its banks.

Phasmidæ (Gr. *phasma*, 'a spectre,' a family of *Orthopterous* insects represented by the 'walking stick' insects, and by the 'leaf insects.' In this group the bodies are of linear conformation, and the wings are either abortive, or when developed are leaf-like. The antennæ are short, and the abdomen is nearly twice as long as the other regions of the body. In *Phasma*, the typical genus, species of which are found in tropical climates, both sexes are winged. In this family the young or larvæ are like the adults, with the exception that in the winged species the wings exist in a rudimentary state in the pupæ.

Pheasant (*Phasianus*), a genus of *Rasorial* or *Gallinaceous* birds, the type of the family *Phasianidæ*. In this group the bill is of moderate length and the wings are rounded. The powers of flight are not markedly developed, and the tail is long and broad. The tarsi are 'spurred,' and the hinder toe is short and raised on the tarsus. In the genus *Phasianus* itself, the tail is long and wedge-shaped, and the nostrils are in a groove at the base of the bill. The fourth and fifth quills are the longest, and the tail is long. The common P. (*P. colchicus*), is a native of Asia Minor, but has become completely acclimatised in Britain and other European countries. It attains a total length of about 2½ or 3 feet. The males have a very brilliantly marked plumage. The head and neck are blue, glossed with green and purple tints, and a patch of scarlet skin surmounts the eye. The back plumage is coloured golden red, varied with black and brown tints and markings. The quill-feathers are brown; the breast is purplish red, and the under parts are brown, tinted with black. The brown tints predominate in the female. The nest of the P. is a rude structure, consisting of grasses, &c., collected on the ground. The eggs number eleven or twelve, and are of an olive brown colour. The P. appears to like mating with other species of *Gallinaceous* birds. Hybrids have been reared between the P. and common fowl, the grouse, the guinea-fowl, and the turkey. The food consists of insects, seeds, and vegetable matters of various sorts. The P. runs swiftly on the ground, but has only limited powers of flight. At night it roosts on the low branches of trees. P.-shooting in England and Scotland begins on October 1st, and ends on February 3d. The birds are fed during winter, and become so tame that P.-shooting in some cases can hardly be termed a sport. The female P., as is the case with the Peacock (q. v.), frequently assumes the plumage of the male when its sexual functions cease; and the male and females remain apart except at the breeding season. The *Argus* P. (*Argus giganteus*) is a species of P. occurring in Sumatra, and derives its name from the volute spots on the chestnut tail. The tail-feathers are extremely long, and the average length of the bird is about 5 feet, tail included. Reeves P. (*P. Reevesii*) occurs in N. China. It is noted for the extreme development of the two central feathers of the tail, which may measure 7 feet long, and which are of a grey colour, barred with dark brown bands. The Golden P. (*Thaumalia picta*) inhabits China, as also does Lady Amherst's P. (*Thaumalia Amherstii*) and the Silver P. (*Gallophasius Nycthemerus*). The Peacock P. (*Polyplectron Napoleonis*) occurs in the Moluccas, and attains a length of 20 inches. Its general colour is brown, varied with white and blackish-brown, the abdomen being black. The name Native P. is given to the *Leipoa ocellata* of Australia, a bird allied to the Jungle Fowl (q. v.).

Pheasant-Shell (*Phasianella*), a genus of *Gasteropodous* molluscs, of which the Australian P. S. (*P. Australis*) is a good example. It was formerly in great demand, and large prices were asked and obtained for good specimens. The P. S. belongs to

the family *Turbinidæ*, or top shells. The colours vary greatly, brown and green tints being among the most common hues.

Phaidias. See PHIDIAS.

Phenomenon (Gr. 'what seems'), a term used by metaphysicians to denote something as perceived by us, not necessarily as it is in itself. The reality which causes or produces it is termed by Kant the *noumenon*, 'what is in the *nous* or mind.' In literature the meaning of P. is less exact; the word being used rather vaguely as a synonym for 'feature,' 'aspect,' 'characteristic.' There is also a vulgar and inaccurate use of the term as equivalent to something wonderful: e.g., 'The Infant Phenomenon' means a baby of enormous size exhibited in shows.

Phenyl, an organic radical having the composition C_6H_5 . Its hydride (C_6H_6) is called Benzol (q. v.), which is of great importance in organic chemistry and in the arts as the source of the aniline dyes. *Phenic alcohol*, *Phenetol*, or *Carbolic Acid* (q. v.), is well known as a powerful antiseptic, and has the formula $C_6H_5.OH$. P. is thus of high theoretical importance as the common radical of a great many most valuable substances. See HYDROCARBONS.

Phœræ, anciently a city of Thessaly, lay in the S.E. corner of the Pelasgian plain, near Mount Pelion, and 90 stadia from Pagasæ, its port. It was famed in mythology as the home of Admetus, and in history as the seat of a race of tyrants founded by Lycophron about the end of the Peloponnesian War, who sought to extend their dominion over the whole of Thessaly. Lycophron was succeeded by his son Jason, who was chosen 'Tagos' (generalissimo) of Thessaly about 374 B.C., and being assassinated in 370, was succeeded by his brothers Polydorus and Polyphron. Polyphron murdered Polydorus, and was himself murdered by his nephew Alexander, a cruel tyrant, who was killed by his wife Thebe and her brothers in 359, in whose hands P. remained till 352, when it fell a prey to Philip II., king of Macedon. Remains of P. are still seen at *Valestino*. See Strabo, lib. ix., and Leake, *Northern Greece* (vol. iv.).

Pherecydes, a Greek sage, was a native of the isle of Syros, and flourished in the 6th c. B.C. He was the teacher of Pythagoras, and himself composed a prose theogony, under the perplexing title *Heptamychos*, in which he maintained that there were three formative principles—Zeus or Æther, Chthona or Chaos, and Kronos or Time; and four elements from which all existing things were formed—earth, air, fire, and water. The fragments of this work were edited by Sturz (Gera, 1798).—Another P., a native of Leros, who resided at Athens in the 5th c. B.C., was author of the mythological history in ten books variously styled *Historia*, *Autochthonæ*, or *Archæologia*. Its fragments are given in C. Muller's *Historicorum Græcorum Fragmenta* (Par. 1840).

Phidias (Gr. 'Pheidias'), son of Charmides, was born at Athens about the time of the battle of Marathon, B.C. 490. He began work as a statuary about 464, under Hegias, and then under Ageladas of Argos, quickly showing that he shared the inspiration of the age. Fortunately for the world, there was not only a P., but a Pericles. Pericles chose him to direct the work of beautifying Athens. The buildings on the Acropolis were the result—the chief of these the Parthenon, with its chryselephantine statue of Athene (so called because the uncovered parts were formed of ivory, the drapery being of solid gold). It was dedicated 438 B.C., and was regarded as an offering from the spoils of Marathon. It stood within the precincts of the Parthenon, and was 40 feet high, exclusive of the pedestal. Some relics of the Parthenon still exist in the British Museum. (See ELGIN MARBLES.) The beauty of the temple and the statue, developed with the utmost elaboration, yet losing none of the severe dignity of earlier styles, touched the limit of art. At some distance stood the great bronze statue of Athene Promachos (70 feet high), whose crested helmet and spear-point could be seen from the sea at Sunium.

From Athens P. went to Elis and to Olympia, where he spent several years in producing the masterpiece of the world, the Olympian Zeus. It was looked upon with such reverence, that except on festivals it was hidden with a veil. It represented the god, not as striving with Titans or hurling thunderbolts upon mortals, but as wrapt in awful repose. P. said that he had striven to represent the Zeus of Homer in this statue. In

434 B.C. P. returned to the Athens which his genius had glorified, only to meet death. Faction was intensely bitter at the moment. Afraid to strike at Pericles, they assailed him through his friends. P. was accused of stealing part of the gold given for the Athenic Promachos, and accused of putting a figure of Pericles and one of himself on the shield of the goddess. This second charge was not one of impiety, but treason. Pericles had been represented as fighting with an Amazon, and this was taken for an allusion to the story of Theseus and Hippolyta, and therefore for a blow at the republic. The ungrateful Athenians cast P. into the prison. Miltiades had been confined in, and there he died, victim of his own greatness, in 432 B.C. See Müller's *De Phidias Vita et Operibus Commentationes* (Gött. 1827), and Lloyd's *Age of Pericles* (2 vols. Lond. 1875).

Phigalia, an ancient town of Arcadia, in the Peloponnesus, stood on a lofty hill, above the modern village of Pavlitz. It was founded prior to 650 B.C., was upwards of 2 miles in circumference, and possessed a temple of Apollo Epicurius, a peripteral hexastyle building of the Doric order, 125 feet long by 48 broad, with 38 columns. This edifice, which, next to the Theseum at Athens, is the best preserved of all the Greek temples, was first described by Chandler in 1765. Its sculptured frieze, representing the contest of the Centaurs and Lapithæ (the Phigalian Marbles), was transferred to the British Museum in 1845.

Philadelphia, the largest city in Pennsylvania, and second only to New York in the United States, lies on the left bank of the river Delaware, 136 miles N.E. of Washington, and 87 miles S.E. of New York by rail. In shape it is somewhat irregular, following the course of the river, towards which it has a front 23 miles in length. The total area is 130 sq. miles. The houses are mostly built of red brick, and with a uniformity of style which is rather monotonous; although within recent years this has been much improved by the introduction of other building materials, such as sandstone and white marble, large quarries of which exist in the neighbourhood. The number of dwelling-houses is unusually large in proportion to the population, and this, together with the excellent drainage, ventilation, and water supply, has made P. one of the healthiest cities in the world. In 1874 its death-rate was 19.66 per 1000. Many streams flow through the city, of which the chief are Schuylkill River, here receiving the Wissahickon and Mill Creeks, and the Hollander's Cohocksink, Gunner's, Frankford, Wissinoming, and Pennypack Creeks, emptying into the Delaware. The Schuylkill is crossed by fourteen bridges, the finest of which is the iron one in Girard Avenue, 100 feet broad and 1000 long. That in Spring Garden Street is a double bridge, carrying an upper and lower street, and is 1290 feet long and 48 wide. The streets are almost without exception built at right angles. In 1875 tramway tracks were laid down over 242 miles of streets, and this traffic employed 5490 horses, and yielded a revenue of \$4,355,231. P. is supplied with water from seven great reservoirs. Another is being constructed (1878) in the East Park, with a storage capacity of 750 million gallons. In 1876 the waterworks supplied a total of 15,097 million gallons on an assessment of \$1,093,864. There are two public parks, Fairmount and Hunting. The former of these, which is 13 miles long by 4 broad (area, 2740 acres), is one of the largest public parks that exist, and includes some natural scenery of great beauty. The finest public buildings are the custom-house, a beautiful Doric structure of white marble; the mint, also of white marble in the Corinthian style; and the post office, with a front of white marble in the French style. These will all be surpassed, however, by the new city hall, commenced in 1872 and now (1878) approaching completion. It is a colossal structure of granite and marble, measuring 470 by 486 feet, built in the Renaissance style. The tower when finished will be 250 feet in height, the loftiest of the kind perhaps in the world, and will be surmounted by a statue of William Penn. The grand lodge temple of the Freemasons, completed in 1876, is a splendid Corinthian structure, erected at a cost of \$1,400,000. P. has three principal theatres (the Arch, Walnut, and Chestnut), an Academy of Music, with a hall seated for 2000, and six minor theatres. The oldest public library in the city is the 'Philadelphia,' founded in 1731 by Benjamin Franklin. It contains about 100,000 vols. Other literary collections are the Athenæum, Mercantile, and Apprentices' libraries, and the Ridgway Library,

the granite building of which was nearly finished in 1876, out of the fund of \$1,500,000 left by Dr. Rush in 1869. In 1870 there were 370 public and private libraries, having 2,985,770 vols. The Pennsylvania Historical Society possesses a number of valuable historical works and MSS., besides a museum of relics and curiosities. There were (1876) in P. 534 churches, of which 104 are Methodist, 102 Presbyterian, 93 Protestant Episcopal, 78 Presbyterian, 71 Baptist, 43 Roman Catholic, 22 Lutheran, 16 Quaker (8 Orthodox), and 9 Jewish. The finest churches architecturally are St. Mark's (Protestant Episcopal), the Roman Catholic cathedral of St. Peter and St. Paul, with a dome 210 feet high, and the Jewish synagogue Roclef Shalom, adorned with arabesques. The University of Pennsylvania, founded as an academy by Franklin in 1749, occupies an area of more than 6 acres, and includes a medical college with accommodation for 600 students. In 1875 it had 44 professors and instructors, and 701 students. Other medical institutions are the Women's, Jefferson's, and Hahnemann's colleges, and the College of Physicians. The principal scientific institutions are the Academy of Natural Sciences, the Polytechnic College, the Wagner Institute (free), and the Franklin Institute. The chief schools of art are the Academy of Fine Arts and the School of Design for Women. There were in 1876 492 public schools, maintained at a cost of \$1,634,653. The benevolent institutions are very numerous, and include 24 hospitals, 21 orphan asylums, 19 homes for the aged, besides several special asylums for the blind, the deaf and dumb, inebriates, &c. There are 28 market-houses, several of which are spacious handsome structures. In 1875 there were sold at the drove-yards 141,000 beef cattle, 11,720 cows, 491,500 sheep, and 243,300 hogs. There are 14 daily newspapers, of which the *Public Ledger* has the largest circulation, amounting to 95,000. In manufacturing industry P. is second only to New York, which it surpasses in the variety of the articles made and the number of persons employed. In 1870 there were 8579 establishments, having an invested capital of \$304,340,637, and employing 152,550 hands, who received \$68,647,874 in wages. In 1875 the value of the exports was \$31,936,727, of the imports \$23,457,334. The principal articles exported were breadstuffs (value 1875, \$9,222,971) provisions, tobacco, coal, petroleum (\$7,927,399), and raw cotton (\$17,819,798); the chief imports being cotton and woollen goods. Grain is shipped by means of elevators: the Girard Point elevator is 124 feet high, has storage for 800,000 bushels, and can load six vessels at one time. The total number of vessels employed in foreign trade which entered the port of P. in 1875 was 1105, with a tonnage of 952,279. There also entered 8238 coasting vessels. P. has direct communication with Europe and many American ports by regular steam lines. Navigation is kept open in winter by three powerful iceboats, owned by the city. Iron shipbuilding is carried on to a considerable extent, and there are large launching and dry docks, shipways, &c. The United States navy-yard, at League Island, is 2 miles long and about half a mile broad, has an area of 923 acres, and a maximum depth of 26 feet. There are at P. two United States arsenals; the one at Frankford produced 10,500,000 cartridges in 1875, while the Schuylkill arsenal has occasionally disbursed clothing and camp furnishings to the value of \$20,000,000 in a year. The city, which is under a mayor and councils, had in 1876 a funded and floating debt of \$69,716,524. According to the municipal census of 1876 the population is 817,448.

The first settlement within the boundaries of P. was made by the Swedes in 1638. William Penn received his charter for Pennsylvania (q. v.) March 4, 1681, and P. was founded in the same year. In 1699 there was a population of 4500. The city received its charter from Penn in October 1701. During the war with Britain, P. was occupied by the British troops under General Howe from September 26, 1777, till June 18, 1778, and the battles of Germantown and Brandywine were fought near it. Congress assembled here 1778-83 and 1790-1800. During the civil war P. adhered strongly to the cause of the Union. The city has rapidly extended in recent years, and building enterprise is greatly stimulated by the action of over 600 building societies. Purchasers acquire lots on no other obligation than to pay interest on the original value of the ground, and can compel sellers to accept payment of the principal when they choose. In 1876 the centennial anniversary of the American Declaration of Independence was celebrated here by one of the most splendid international exhibitions the world has ever seen.

It was opened by President Grant on May 10, and from that time till its close on the 10th November it was visited by 9,789,392 persons, and the receipts for admission amounted to \$3,813,742. The exhibition was situated in Fairmount Park, and the entire buildings covered an area of 75 acres. See *The Official Guide-Book*, by Thompson Westcott (Phil. and Lond. 1876), and *Étude sur l'Exposition*, by Eugène Lacroix (1877).

Philæ, the name of two small islands in the river Nile, 6½ miles above Syene. P. proper, 'the Loretto of Ancient Egypt,' is the smaller of the two. It is 417 yards long and 130 broad, and is of syenite stone; its sides are high, with steep escarpments, and crowned with high walls. In early times it was held to be one of the burying-places of Osiris, and was supposed to be 'unapproachable' by either birds or fish; but by the time of Ptolemæus Physcon (170-117 B.C.) it was so frequented by pilgrims to Osiris' tomb, and traders between Meroc and Memphis, that the priests begged that king to relieve them from the burden of excessive hospitality. The hieroglyphic characters of this petition, engraven on an obelisk brought to England by Mr. Banks, when compared with those on the Rosetta stone, have shed much light on the phonetic alphabet of ancient Egypt. Monuments dating from the age of the Pharaohs to that of the Cæsars cover both islands. The oldest remains of any size are of a temple of Athor (the Egyptian Aphrodite), built in the reign of Nectanebus I. (378-360 B.C.). The walls of the chief temple of P., dedicated to Ammon-Osiris, are everywhere covered with symbolic figures and representations of the myths concerning that god. This temple (435 feet long by 135 broad) was rudely defaced by Christian Iconoclasts, who converted its pronaos into a church of St. Stephen. The modern name of P. is *Jesiret-el-Nirbeh* ('island of temples'). The hieroglyphic name of the smaller island was *Philak* ('boundary').

Philemon, Epistle to, was addressed by St. Paul to P., a personal friend and apparently a convert of the apostle (*cf.* 13, 19), residing at Colosse (*cf.* 1, 2, with Col. iv. 9, 17), regarding Onesimus, a runaway slave belonging to P., whom Paul had converted (10), and who was returning to his master. The epistle was received into the canon from the first, and that it was written by St. Paul was unquestioned till the time of Baur, who considers its language to be un-Pauline, and some of its contents improbable; but his 'criticism' has not been generally accepted by scholars. Baur himself was not very sure about the validity of his own doubts. The time and place of writing are determined by the Epistles to the Colossians and Philippians. The apostle was a prisoner at the time (22), as when writing the Epistle to the Philippians (ii. 23, 24), and Onesimus seems to have travelled in company with Tychicus, the bearer of the Epistle to the Colossians (iv. 7-9). It was therefore probably written from Rome about 62.

Philemon and Baucis, in classic mythology, a pair of Phrygians, who hospitably received Zeus and Hermes in the disguise of ordinary men, after they had been denied shelter by every one. For this Zeus took them to an adjoining mountain, while all the surrounding country was covered with a flood, made them guardians of his temple, and granted them the only boon they requested, that they might die at the same moment. Their story has been finely treated by Ovid in his *Metamorphoses*.

Philibeg (Gael. *feileadh*, 'cloth or covering,' and *beag*, 'little'), an article of male apparel, and the characteristic garment of the Scottish Highlanders. It resembles a short petticoat, being suspended from the waist and only extending to the knees. In the lowlands of Scotland and in England the P. is better known by the name *kilt*, a Saxon word signifying 'a tucked-up garment.' The P., which is made of Tartan (q. v.), is usually covered in front by the *sporran* (Gael. 'a purse or pouch'), formed of an animal's skin, and frequently tasselled and otherwise ornamented.

Philidor or Danican, François André, a celebrated composer and chess-player, born at Dreux in Orléannais, September 7, 1726; after studying music at Paris (1736-45), made a tour through Holland, England, and Germany, everywhere gaining a marvellous reputation for his skill at chess. In 1754 he returned to Paris, and devoted himself earnestly to music, his first opera, *Elise le Sauveteur* (1759), being followed by twenty others in the course of the next eighteen years. He revisited London, and there published his *Traité du Jeu d'Echecs*

(1777), at Fontainebleau brought out *Thémistocle* (1785), the finest of all his operas, and died at London, whither he had been driven by the Revolution, August 30, 1795. P.'s system of chess-playing is shown in his maxim: 'Pawns are the soul of chess.' See *Allen's Life of P.* (Phil. 1864).

Philip II, King of Macedonia, the youngest son of King Amyntas II. by his wife Eurydice, was born at Pella in 382, and brought up with great care at Thebes, whither Pelopidas had carried him as a hostage. On the death of his brother Perdiccas III., P. became regent of Macedonia and guardian to his infant nephew Amyntas, but in a few months he himself assumed the royal power and title. The step was justified by the danger of the kingdom, harassed by the Pæonians on the N. and the Illyrians on the W., and at home agitated by the rivalries of Pausanias and Argæus. Reorganising the army on the plan of the phalanx, he fell upon Argæus and defeated him, immediately afterwards concluding a peace with the Athenians, by whom Argæus had been supported. The Pæonians were speedily reduced, and the Illyrians forced to sue for peace with the loss of a portion of their territory. In one year P. had freed himself from a position of great peril; he now set himself to carry out his ambitious aims. Soon after his accession he had declared Amphipolis free, in order to please the Athenians, who had aided Argæus in the hope of gaining that city; but afterwards, making a pretext for war, he besieged and took it in 358. P. had previously formed a secret treaty with the Athenians, by which he undertook to make over to them Amphipolis in return for Pydna. He now took Pydna without a struggle, and refused to stand by his engagement with Athens. To gain the good-will of the Olynthians P. gave them the town of Potidea, taken from the Athenians in 356. He then took a Thasian settlement named Crenides, which he renamed Philippi (q. v.). In 352, after a long siege, he took Methoné, and marched thence into Thessaly to join the Aleuadæ against Lycophron of Phære, who was aided by the Phocians. In a short time he overran Thessaly, and advanced to Thermopylæ, from which, guarded by a strong Athenian force, he thought it prudent to retire. He now overran Thrace, and in 349 returned to commence an attack on the cities of Chalcidice. Demosthenes (q. v.) had already seen the real object of P., and in his first Philippic oration (352) endeavoured to rouse his countrymen to a sense of their danger. The Olynthians appealed to Athens, and by the famous Olynthiac orations Demosthenes induced his countrymen to aid their cause. But by 347 all the Chalcidic cities were in P.'s hands, and in 346, after making peace with Athens, he marched into Phocis (q. v.), and put an end to the Sacred War. His ascendancy in the Amphictyonic Council was henceforth complete, and he was appointed joint-president of the Parthian games. From 342 to 340 P. conducted an expedition in Thace for the purpose of subduing the Greek cities in that country. Phocion was dispatched by the Athenians to counteract his efforts, and in 339 compelled him to raise the siege of both Perinthus and Byzantium. In the same year the Locrians of Amphissa, for tilling a portion of the sacred land, had been attacked by the Amphictyones, and in 338 they gave the command of their army to P., who marched through Thermopylæ and seized Elatea. The Athenians, hastily forming an alliance with the Thebans, were defeated by P. in August 338, at Chæronea. Greece was now at P.'s feet. He had long cherished the design of invading the Persian Empire at the head of a united Hellas. At a congress held at Corinth this was now determined on. Early in 336 he sent troops into Asia, under Parmenion, to gain over to his side the Greek cities, but in the summer of the same year he was murdered by a noble youth named Pausanias, at a festival held at Aegæ, on the occasion of the marriage of his daughter with Alexander of Epirus. Aristotle states that the deed was due to a private quarrel, but suspicion was attached to Alexander his son and Olympias (q. v.) his wife, who had been offended at his marriage with Cleopatra, daughter of Attalus, in the previous year. P. was a liberal patron of art and science, and a clement conqueror; but his passions knew no bridle save ambition. In politics he was a master of duplicity; yet only a policy like his would have enabled Hellas to resist the fiercer violence of Rome.—**P. V.**, King of Macedonia, was the son of Demetrius II., and was born 203 B.C. He was only eight years old at the death of his father Demetrius, but till 220 his uncle Antigonus Doson ruled as king. During the first three years of his reign P. led with great success the war against the Aetolians

at the request of the Achæans and Aratus. This war, commonly called the Social War, he concluded in 217. Becoming jealous of his old friend and counsellor Aratus, he caused his death by poison in 213. Meanwhile P. had engaged in a war with the Romans. He formed an alliance with Hannibal in 215, and from 211, when the Romans received the Ætolians as their allies, he gained various victories over the latter, till peace was made in 205. Another war with the Romans broke out in 200, but the complete defeat of P. by the consul Flamininus at Cynoscephalæ in 197 brought it to a sudden end. Finding that he had put to death his son Demetrius on a false accusation, he is said to have died of grief, 179 B.C.

Philip II., King of Spain, was the son of Karl V. and Isabella of Portugal, and was born at Valladolid, May 21, 1527. The heir of the largest empire in the world, he was carefully educated, and early initiated into statesmanship and war. His father's efforts at the Diets of Augsburg and Regensburg to get him elected King of Rome having proved ineffectual, P., whose first wife, Mary of Portugal, had died in giving birth to the Prince Carlos, married Mary of England in 1554, and supported the title of king of that country, as well as the sovereignty of Naples and Milan. The jealousy of the English, and their reluctance to allow him any share in the government until the birth of a son, drove him to Flanders, where he became, by the abdication of Karl V. at Brussels, October 25, 1555, sovereign of the Netherlands; and January 16, 1556, King of Spain and all its vast dependencies in the New World. He found himself almost immediately on his accession at war with the Pope and his ally Henri II. of France. His arms were successful in Italy under the Duke of Alba, and in France under Philibert, Duke of Savoy, and Count Egmont, at St. Quentin (10th August 1557), and at Gravelines (13th July 1558). In this year, however, England, his ally, lost Calais, and was obliged to cede it to France at the peace of Cateau Cambresis (2d April 1559)—a peace which P., after his rejection by Elizabeth of England, cemented by marrying Elizabeth, daughter of Henri II. of France, who had been betrothed to his son Carlos (q. v.). He now fixed his residence at Madrid, and built the Escorial (q. v.). P. next imposed upon himself the task of destroying all civil and religious liberty within his dominions, and with this view established the Inquisition, which, however, was vigorously resisted in the Netherlands, and roused a spirit of insurrection which grew into revolution, and, notwithstanding the terrible severity of Alba, and the military genius of Don John of Austria and Alessandro Farnese, achieved the independence of the northern provinces in 1579. In 1580, when the direct male line died out, P. acquired Portugal, which was annexed to Spain for sixty years. His anger against the English as promoters of the rebellion in the Netherlands led to his great attempt to conquer England by the 'Invincible' Armada (q. v.), which was so disastrously foiled. For four years (1589-93) he lent his aid to keep the Protestant Bourbon from the French throne, but he was compelled to recognise him as Henri IV. at the treaty of Vervins (2d May 1598). P. died of a loathsome disease, September 13th of the same year, at the Escorial, leaving a son by his fourth queen, Anne of Austria. Few princes have had so many biographers, and seldom has the verdict of history been so unanimous in its condemnation. With excellent abilities but little real insight or wisdom, he failed in all his greatest undertakings, and did fatal evil to Spain by crushing out the old heroic spirit which had made her pre-eminent among the nations of Europe, and destroying by a cruel and gloomy bigotry every promise of advancement in religious thought or civil freedom. See Campana, *Vita del Don Filippo d'Austria*; Herrera, *Historia del Mundo en el Reynado del Rey Philippe II.*; Cordova, *Vida de Felipe II.*; Dumesnil, *Histoire de Philippe II.*; San Miguel, *Historia del Rey D. Felipe II.* (4 vols. Madr. 1824-25); Gachard, *Correspondance de Philippe II.* (3 vols. Bruss. 1848-59); Don Carlos et Philippe II. (Bruss. 1863); Prescott, *History of the Reign of P. II.* (1855-58); and Motley, *History of the United Netherlands* (1860-65). — **P. V.**, first Bourbon king of Spain, was the grandson of Louis XIV., and was born at Versailles, December 19, 1683. By the last testament of his uncle, Carlos II., in 1700, he was declared heir to the Spanish throne. However Karl, Archduke of Austria, great-grandson of Philip III. of Spain, established a rival claim, and was supported by England, Austria, and Holland, and afterwards by Prussia, Denmark, and Hanover. The war known as the War of

the Spanish Succession (q. v.) continued with varying fortune until 1713, when the throne was secured to P. by the peace of Utrecht. In 1714 his queen, Louisa Maria of Savoy, died, and P. married the ambitious Elizabeth Farnese of Parma, who, influenced by Alberoni (q. v.), induced him to attempt the recovery of Sicily and Sardinia. He was compelled by the Quadruple Alliance (France, England, Austria, and Holland) to lay aside his schemes and dismiss Alberoni, but in 1731 he joined France and England against the Emperor, and in 1736 acquired the kingdom of the Two Sicilies for his son Carlos. In his later years P. became almost idiotic, and could only be aroused from his mental stupor by the songs of Farinelli. He died at Madrid, July 9, 1746. See Targe's *Histoire de l'Avènement de la Maison de Bourbon au Trône d'Espagne* (8 vols. Par. 1776); Coxe's *Memoirs of the Kings of Spain of the House of Bourbon* (3 vols. Lond. 1813); Viollet's *Hist. des Bourbons en Espagne* (Par. 1843); and Lord Mahon's *War of Succession in Spain* (Lond. 1832).

Philippe I. of France, son of Henri I. and Anne of Russia, was born in 1052, and named after Philip of Macedon, because of a supposed genealogical relationship between that potentate and his mother. He was consecrated king in 1059. Great events took place during his long reign, but P. is not associated with them. In 1071 he attacked Robert the Frisian, who had seized Flanders, but was shamefully defeated. He was more successful in 1076, having driven back the Normans, who were endeavouring by an alliance with Aquitaine to establish a strong power from the Seine to the Pyrenees. In 1094 he was excommunicated, and summoned to appear at the Council of Piacenza, having divorced his wife, and carried off Bertrade, wife of Fulk of Anjou. He was again excommunicated in 1100, before which he had turned the enthusiasm of his neighbours over the first Crusade to some account by buying a footing on the south bank of the Loire. The same year he associated with him in the sovereignty his son Louis, and eight years afterwards this weakest of the Capets died at Melun (29th July 1108), reconciled to Rome. See Oedericus Vitalis, the French histories of Sismondi, Michelet, and Martin, and Kitchin's *History of France* (vol. i. 1873). — **P. II.**, known as Auguste the Magnanimous, son of Louis VII. and the beautiful Alix of Champagne, was born 22d or 25th August 1165. At the age of fifteen he was crowned at Rheims, the twelve nobles who held the great fiefs immediately from the crown being present. His earliest dreams were of restoring the old Karoling power in its entirety, and says Kitchin, 'For forty-three years he pursued this end, and brought to bear on it a cold pertinacity, a freedom from uneasy scruples, a clear sagacity in conceiving crafty plans, and constancy in carrying them out.' One of his first public acts (1182) was to banish the Jews from his realm, after having plundered them of their goods; and to proclaim punishment of death to profane swearers. He had already shown his independence of character by marrying Isabelle of Hainault, niece of the Count of Flanders, against the will of his uncles. No sooner was his father dead than all the great vassals rose in rebellion, and P. had to embark (1185) on a series of wars, subduing first of all the Count of Flanders, and next the Duke of Burgundy. He then turned his attention to Normandy and the south, and (1186) waged war with Richard the Lionheart in Aquitaine—a war which ended in the friendship of the combatants, and gave P. the opportunity of intriguing with the other sons of Henry II. against their father. In 1188, Henry, betrayed by his sons, was compelled to declare himself liegeman in full, and to yield Berri. With much reluctance P. went on a crusade (1190), wintering in Sicily with Richard, landed at Acre or Ptolemais (13th April 1191), grew tired of the skirmishings, swore to his rival that he would protect his territories, and returned home. On his way back he tried to get quit of his oath by Papal intervention, but failed. He then intrigued against Richard through John, and on the tidings of the former's captivity reaching France, he attacked Normandy, and by a truce in 1196 became master of Auvergne, after a wasting war with his rival. But in 1197 his great vassals turned towards Richard, and hard times might have overtaken P. had not Innocent III. interfered in the interests of peace. On the death of Richard, Anjou, Maine, Poitou, and Touraine declared their allegiance to Arthur of Brittany instead of to John. P. took these under his protection, and in the name of Arthur dismantled every town he took in Brittany. Meanwhile (1199), having taken a dislike to his second wife, Ingeborg

of Denmark, he dissolved the marriage with her, but only to suffer the penalty of excommunication, an inconvenience which made him make peace with John. The murder of Arthur in 1202 once more roused P., and he took arms against John, attacked and captured Château Gaillard (1207), overran Normandy and seized Rouen in the same year, consolidating his conquests in the kingdom of France. To give them the appearance of legality, he summoned 'the twelve Peers of France,' six laymen and six ecclesiastics, to form a court. P. stood aloof from the religious war in Provence, though in 1215 he accepted the homage of Simon de Montfort, who had taken for himself the heritage of Toulouse. In 1214 he had crushed the coalition of barons and princes, by the decisive battle of Bouvines, a battle 'which roused the national spirit as nothing else could; it was the nation's first taste of glory.' P. sanctioned the expedition of Louis to England in 1216; but he resisted every effort of the Roman court to embark him in the Albigensian crusade. In his later days he became devout, and attended to all clerical ordinances. He died of fever at Mantes, July 14, 1223. He left an enormous fortune to his son, and a great reputation. P. was proud, patient, brave, and deceitful, eminent in the science of war, sagacious in politics, a lover of literature, and a reformer of cities. See Rigord, *De Gestis Philippi Augusti*; Guillaume le Breton, *De Vita et Gestis Philippi*; Baudot de Juilly, *Histoire de P. Auguste* (2 vols. Par. 1704); Lussan, *Anecdotes de la Cour de P. Auguste* (6 vols. Par. 1733-38); Capeligue, *Histoire de P. Auguste* (4 vols. Par. 1829); the French histories of Sismondi, Michelet, and Martin; and Kitchin's *History of France* (vol. i. 1873). —**P. III.** ('le Hardi'), son of Louis IX. and Marguerite de Provence, was born 3d April 1245, married in 1262 Isabella of Aragon, was on a crusade with his father at the time of his death, and bore back his bones from Tunis to France (1269-70). He was utterly illiterate, but surrounded the throne with lawyers. Edward I. did homage to him for the lands he held of him. He encouraged favoritism, held one great tournament, which at least proves he did not need to be jealous of his own vassals. In 1285 he led an expedition against Pedro, King of Aragon, and ruined thereby both fleet and army. This adversity induced a fever, of which he died at Perpignan, 5th October of the same year. His reign was a period of great tranquillity for France. See Guillaume de Nangis' *Gesta Philippi Audaci*; the French histories of Sismondi, Michelet, and Martin; and Kitchin's *History of France* (vol. i. 1873). —**P. IV.** ('le Bel'), son of preceding, was born at Fontainebleau in 1268, succeeded to the throne in 1285, and from contemporary descriptions of him seems to have been tall and handsome, though proud and taciturn. Lawyers continued to guide the royal policy, and in the direction of absolutism. From 1285 to 1296 nothing of importance occurred save the languid prosecution of war in Aragon and Sicily, and the payment to Edward I. of 10,000 livres for a renunciation of his claim on Normandy. From 1296 to 1304 was filled with the events of his quarrel with the Pope and the war with Flanders. Boniface VIII. offended P. first of all by mediating between him and Edward, then by ordering him to release the daughter of Guy of Flanders, and lastly (1296), by issuing a bull, entitled 'Clericis laicos,' in which ecclesiastics were forbidden to pay taxes of any kind to the civil power without the permission of the apostolical see. This was met on P.'s part by an ordinance forbidding the export from the kingdom of anything of value except with his permission. Fresh threats were thundered from Rome, and cast back by P. Nuncios were dispatched, and the dispute ended for that time by the issue of a fresh bull excluding France from the operations of 'Clericis laicos.' But after again mediating between P. and Edward, the attitude of antagonism began to reappear. The year 1300 witnessed a revival of faith in Christendom. The Pope sent an arrogant legate to France, who attempted to stir up rebellion. A bull claimed for the Pope supremacy over all temporal authorities. It was solemnly burnt by P.; the estates of France were called (1302), and declared against the Roman pretensions. The decretal of 'unam sanctam' (18th November) affirmed that the spiritual ought to judge the temporal power, and issued excommunications against all who tried to despoil those going to Rome. P. hesitated, but in 1303, by intriguing against the Pope at Rome, he had him imprisoned, and subjected to such indignities that he died. In 1304 Clement V. cancelled the obnoxious bull, and became in a large measure subservient to P. In 1304 the struggle in Flanders ended in a recognition

of its independence, the eldest son of Count Guy doing homage. The epoch on to 1314 is marked by the doom slowly prepared by P. for the Order of the Templars, whose power and wealth were a source of uneasiness to him. They were all arrested in October 1307, and their goods seized. Clement was asked to condemn them, and being in France, P. declined to let him return to Rome unless he consented. In 1310 many of the knights were burned at the stake. The king's ferocity grew with his years, until in 1314 a great confederation was formed in the country against his tyranny. He expired 29th November 1314, at Fontainebleau, having added to French territory, but leaving a name odious in the mouths of his people. See Guillaume de Nangis' *Chronicon*; Bontaria's *La France sous P. le Bel*; the French histories of Sismondi, Michelet, and Martin; and Kitchin's *History of France*, vol. i. 1873). —**P. V.** ('le Long'), second son of preceding, was born in 1293, hastened on the death of his nephew to be crowned at Rheims (1316), after which he returned to Paris, declaring that no female could succeed to the crown of France. The chief events of P.'s reign are of a sinister character. He persecuted the Franciscans, who were preaching the primitive simplicity of the early Church, and encouraged the savage superstition by which life was rendered miserable to the Jews. He died 3d January 1322. See Kitchin's *History of France* (vol. i. 1873). —**P. VI.**, of Valois, son of Charles of Valois, became regent on the death of Charles IV., was born in 1293. A great feudal lord, he was crowned king at Rheims (May 29, 1328), his rival in succession being Edward III. of England, son of Isabella of France, Philippe le Bel's daughter. P.'s reign opened with a successful campaign in Flanders, which removed the blot of Courtrai, and entitled him to enter Paris with much pomp. By 1331 Edward III. had, with the advice of his parliament, seen it to be best to do homage. But angered by the faithlessness and greed of P., he declared war (1337), which did not finally cease till the battle of Chatillon (1453). Nothing save marchings, counter-marchings, and slight unimportant skirmishes took place until June 24, 1340, saw the naval force of France entirely swept away at Sluys. It was not till the 26th August 1346, after the battle of Crécy and the fall of Calais, that a truce, which lasted for some time, was concluded between the kings. In 1347-48 the black plague struck desolation into the country, and the miseries of P.'s reign were rendered still more dark. Before he died (August 22, 1350) he added, by purchase, Vienne and Majorca to his kingdom. But he had ground down the people of France with heavy imposts, had retarded trade, broken the strength of chivalry, and sold offices, titles, and even nobility. 'All things,' says Kitchin, 'seemed to be evil in France. Oppression, war, pestilence, faithlessness in king and people, days of shame and distress.' See Froissart's *Chronique*; Lévesque, *La France sous les cinq premiers Valois*; the French histories of Sismondi, Michelet, and Martin, and Kitchin's *History of France* (vol. i. 1873).

Dukes of Burgundy. —**P.** ('le Hardi'), fourth son of Jean, King of France and Bonne of Luxembourg, was born January 15, 1342, distinguished himself at Poitiers, where, though a child, he stood by his father, and ward off the blows directed at him. On that field he gained the title 'le Hardi.' In 1363 his father bestowed on him the duchy and peerage of Burgundy, which was afterwards ratified by Charles V. Three years later he married Margaret of Flanders, and on till 1372 he operated against the English in Northern France. He fought the successful battle of Rosbeck against the Flemish in 1382, and in 1384 Flanders fell into his hands in right of his wife. 'He was,' says Kitchin, 'wise and conciliatory, restored the Flemish liberties, and was himself more a Fleming than a Lily prince.' And thus the foundation of the great Burgundian dukedom, stretching in a curve from the sea round the whole northern and much of the eastern frontier of France, was securely laid. On the king showing symptoms of madness, he seized the government (1392), and occupied himself with repelling the English invasion. He died 27th April 1404, at the Château of Hall, Hainault. —**P.** ('le Bon'), grandson of the preceding, son of Jean Sans Peur and Margaret of Bavaria, was born at Dijon, June 13, 1366, and on the murder of his father succeeded to the duchy of Burgundy. At Arras, in 1419, he recognised Henry V. of England as Regent of France and heir to the throne; in 1429 he went over to the side of the King of France, but on the cession of Champagne returned to his English allegiance.

Again, in 1435, through Papal influence, he entered into an alliance with Charles, though later on P. harboured the Dauphin (afterwards Louis XI.) when the latter mutinied against his father. In 1454 he put down with a strong hand a revolt of the citizens of Ghent. He died July 15, 1467, leaving Burgundy at the highest pitch of prosperity it ever reached. See Barante's *Histoire des Ducs de Bourgogne*; Michelet and Martin's French histories; and Kitchin's *History of France* (vol. i.-ii. 1873-77).

Philippeville, a town in the province of Constantine, Algeria, situated on the Gulf of Stora. It occupies the site of the ancient town of Russicada, was founded by Marshal Valée in 1837, and possesses some handsome public buildings. P. is connected by rail with the town of Constantine, 40 miles to the S.S.W., and is the outlet for a fertile district. Large sums have been expended on its harbour works, with the result of making P. the third port in Algeria. The imports in 1874 amounted in value to £1,107,000, and the exports to £1,498,000. Of the latter, the chief were grain, tobacco, flax, and cotton, as well as marble from the celebrated quarries of Filfila, in the neighbourhood. Pop. (1876) 13,736.

Philippi, a famous city of Macedonia *Adjecta*, on a steep height of Mount Pangæus, between the rivers Strymon and Nestus. Founded by Philip II., King of Macedon, on the site of an old town called Crenides ('fountains'), a Thasian colony, for the sake of the rich gold mines lying near, it is celebrated in history as the scene of the victory gained in 42 B.C. by Octavianus and Antonius over Brutus and Cassius, and also as the place where Paul first preached in Europe, A.D. 53. The ruins of P. are now called *Filibah* or *Felsbejek*.

Philippians, Epistle to the, was written by St. Paul to the Christians at Philippi in Macedonia, which was the first European city visited by the apostle (Acts xvi.), and where, after he left, the work was carried on by Luke, Timothy, Clement, and Epaphroditus (iv. 3, 18), being visited a second time by himself on his third missionary journey. The Pauline authorship of the epistle, for which the testimony of antiquity is abundant and unanimous, has been questioned in modern times, although the doubters have not found many supporters. It was obviously written at the same time and place as, but after, those to Philemon (q. v.) and the Colossians (q. v.), that is, probably during his captivity at Rome (cf. i. 13, iv. 22), about 62. The chief object of the epistle was to warn his readers against certain Judaizing teachers (iii.).

Philippics (Lat. *Philippicæ orationes*), a common expression for orations of great vehemence and invective, derived from Cicero's naming his fourteen speeches against Antonius after the three great orations of Demosthenes against the pretensions of Philip II., King of Macedonia.

Philippine Islands, the northerly group of the Malay Archipelago, 1200 in number, lying to the N. of Borneo and the Celebes, and between the Pacific Ocean on the E. and the Chinese Sea on the W.; lat. 5° 32'–19° 38' N., and long. 117° 14'–126° 4' E. Total area estimated at 120,000 sq. miles. Pop. of the area under Spanish government (according to Dr. A. B. Meyer in the *Mittheilungen* for 1874), 7,451,352. The largest islands are Luzon (51,300 sq. miles; pop. 4,540,191); Panay (11,330 sq. miles; pop. 1,052,586); Mindanao (25,000 sq. miles; pop. 191,802); Samar (13,020 sq. miles; pop. 250,062); Mindoro (12,600 sq. miles; pop. 70,926); Leyte (10,080 sq. miles; pop. 285,495); Zebu (2352 sq. miles; pop. 427,356); Negros (6300 sq. miles; pop. 255,873); and Bohol (6000 sq. miles; pop. 283,515). Luzon (q. v.), on account both of size and population by far the most important of the group, is the most northerly, while Mindanao, the next in importance, is the most southerly. Mindoro Sea, on the S.W., is portioned off from the Celebes Sea in the S. by the Sulu Islands, and from the Chinese Sea in the N. by the long narrow island of Palawan or Paragao. The whole of the islands, which are of volcanic formation, have singularly contorted outlines, and rise in bold, irregular mountain masses, attaining a height occasionally of over 7000 feet, and covered to their tops with dense forests of enormous trees. The soil everywhere is remarkably fertile, and as water abounds both in lakes and rivers, and the climate is hot and humid, the flora develops in almost gigantic proportions. The principal trees are teak, ebony, and cedar, and there is also a rich growth of iron and sapan wood and gum trees. Among the numerous

fruit trees are the cocoa-nut, bread-fruit, orange, citron, tamarind, and mango, while the forests are overgrown and fantastically draped with garlands of huge climbing plants and brilliant parasites. In the valleys and on the mountain slopes are cultivated the famous abaca or manila hemp, tobacco, cotton, sugar, coffee, indigo, rice, wheat, maize, pepper, ginger, vanilla, cinnamon, &c. Manila hemp is exported to the amount of over 30,000 tons annually. Tobacco (a Spanish government monopoly yielding 33 per cent. of clear profit) bears a yearly gross receipt of £1,062,041. There are none of the larger wild animals, but the forests swarm with monkeys, squirrels, humming-birds, birds of paradise, turtle doves, paroquets, fire-flies, and bees; and the jungles with lizards, snakes, mosquitos, huge tarantulas, &c. The rivers and lakes, which abound with fine fish of great variety, are haunted by crocodiles. The chief kinds of game are the deer, wild-boar, pheasant, and duck. The coast caves are the resort of myriads of large bats, and the repositories of the edible swallow's nest of commerce. Other articles of industrial value found in abundance along the shores are mother-of-pearl, coral, tortoise-shell, and amber. Peculiar, but excellent breeds of oxen, buffaloes, horses, goats, sheep, and swine are reared extensively. Gold occurs in the river-beds, and iron and coal are found plentifully. Other minerals extensively distributed are copper, vermilion, quicksilver, saltpetre, marble, and especially sulphur, which exists in immense quantities, both pure and mixed with iron, arsenic, and copper. The P. I. contain many active volcanoes, and are frequently visited by destructive earthquakes, such as that which devastated the province of Zamboango (Mindanao) in 1864. Near Tibi, E. of the great Yriga volcano, hot springs like those of Iceland, New Zealand, and the Yellowstone region, have deposited silicious incrustations displaying beautiful varieties of form and colour. The rainy season extends from May to December, but for the rest of the year the weather is generally fine and the heat moderate. At times, however, violent hurricanes sweep along the shores, especially during the change of the monsoons. The chief trading ports are Manila in Luzon and Iloilo in Panay, and these, together with Zebu, are the only harbours open to foreign commerce. The differential duties were abolished in April 1871, but were reimposed in July following, the Spanish importer being privileged to the extent of 25 per cent. In 1875 there entered the open ports 314 vessels of 179,412 tons, and of these 111 were British vessels of 78,154 tons. The total exports in 1875 (chiefly sugar, hemp, coffee, cigars, tobacco, sapan wood, indigo, and gum mastic) amounted to \$19,466,839 (\$15,727,262 from Manila alone); exports (1875) to Great Britain direct were valued at \$4,157,313, to Australia at \$933,832, to Singapore at \$1,071,664, and to Hong-Kong at \$650,977. The native inhabitants of the cultivated lowlands are chiefly Tagalese and Bisayans, of whom the majority are Mohammedans (*Moros*), skilled in the production of various textile fabrics, silver and gold ornaments, cigar-cases of fibres, and beautiful coloured mats. The interior and mountain districts are inhabited by negro tribes, of whom little is known but that they are heathens, and that physically they strikingly resemble the Papuans. Besides paying a slight poll-tax (\$2 per family), the natives are held liable by the Government to render forty days' labour yearly in making roads, bridges, &c. In the province of N. Luzon the Government tobacco culture is carried on by 957,427 impressed workmen (*polistas*). There is a large mestizo class of Chinese paternity, the Chinese who visit the islands being only temporary settlers, and never bringing their wives. The half-castes are disaffected towards the Government; the last military insurrection, punished with sanguinary vengeance, took place at Manila in January 1872. The governor-general, appointed direct from Spain, resides at Manila, but the provinces are under local governors, and the *pueblos* or townships under chiefs. The army, comprising seven regiments of infantry and one of cavalry, is entirely composed of natives, with the exception of two Spanish brigades of artillery and a corps of engineers. There is a small navy, the most serviceable and characteristic vessels being the feluccas of the coast service. The Church is under an Archbishop of Manila and three bishops; the education of the people is shamefully neglected.

The islands were discovered in 1521 by Magellan, who reached Tamar on the 6th March of that year, and was killed in an encounter with the natives of Matan. In 1565 Villabos led an expedition to the island of Zebu, and named the whole group in honour of Philip II., then Prince of Asturias. From the middle

of the 16th c. the P. I. became the emporium of a rich trade between China and Spanish America. The yearly voyage of a galleon from Manila to Acapulco, with spice and silk to exchange for silver, was proverbially the richest venture of that age. This trade was destroyed by prohibitory laws, intended to favour the mercantile and manufacturing monopolists of Spain. The seat of the Spanish government was transferred from Zebu to Manila in 1581. The comparative failure of trade in modern times is due to a niggardly fiscal system, the restrictions on foreign shipping, and the abandonment of the natives in temporal as well as spiritual affairs to the rule of parochial priests. See Semper's *Die Philippinen und ihre Bewohner* (Würzb. 1869), and *Reisen im Archipel der Philippinen* (3 vols. Leipz. 1867-72), F. Jagor's *Travels in the Philippines* (Lond. 1875), and Dr. Th. Mundt-Lauff's *Negritos der Philippinen* in the *Deutsche Geographische Blätter* (Brem. 1877).

Philippins (from Philip Pustioswiät, one of their earliest leaders), or **Starovery** ('Old Believers,' from *stary*, 'old,' and *vera*, 'faith'), a Russian sect, settled since 1700 in Lithuania and East Prussia. They are a branch of the Raskolniks (q. v.), and cling persistently to the ancient liturgy of the Russo-Greek church, discountenanced by the authorities for more than two centuries. They refuse to serve as soldiers, reject oaths, and for the regular priesthood they substitute celebrated elders of their own, called *Savriks*, who rebaptize all converts to their opinions. Though they have at times run into wild fanatical excesses, the P. are now peaceable and industrious people, whose chief pursuit is the tillage of the soil.

Philippopolis (Turk. *Filibé*; Bulgar. *Plowdi*), a town of Rumilia, vilayet of Adrianople, on a small island in the river Maritza (which here becomes navigable), 90 miles W.N.W. of Adrianople by rail. The island rises to a height of some 500 feet in the triple syenite hill of Bunardchuk ('hill of springs'), which is conspicuous over the great fertile plain stretching away in the N. to the Balkans. The town, founded by Philip, father of Alexander the Great, was taken by the Turks in 1360. The old Greek and Byzantine town, now the Turkish quarter, occupies the heights, and is surrounded by that of the Jews (*Marash*), of the orthodox Bulgarians and Armenians, of the Catholic Bulgarians (*Parlikans*), and of the gypsies (*Ziganka-Mahale*). There are thirty mosques, six Greek and three Bulgarian churches, and one Roman Catholic church to hold 8000 persons. P. is one of the most important trading towns of Turkey, and the seat of a great fair on 27th August. It manufactures silks, cottons, and leather, and trades in the produce of the vicinity, including wine, rice, and silk. Pop. 45,000, of whom eleven-fifteenths are Mohammedans, one-fifth Christian, one-fifteenth Jewish and gypsy. During the late war, the Turks under Suleiman Pasha, who had fallen back upon P. after the forcing of the Schipka Pass, retired precipitately on the sudden appearance of Gourko, and the Russians entered the town unopposed, January 16, 1878.

Philippsburg, an ancient imperial fortress on the Rhine, 16 miles N. of Carlsruhe. After the Thirty Years' War, in which it played a prominent part, it was ceded to France; in the War with Louis XIV. it was recovered for Germany by Charles of Lorraine; and in 1688 it was taken by the French under Vauban, but restored at the Peace of Ryswick. Again captured by the French in 1734, when their leader the Duke of Berwick was killed, it was only held till 1735. It was finally dismantled by the French in 1800. There is a village of the same name with 2317 inhabitants.

Phillips, Ambrose, was born about 1671 in Leicestershire, studied at St. John's College, Cambridge, and in 1709 published his *Pastorals in Tonsori's Miscellany*. These pieces having been extravagantly praised by Tickell, P. became an object of bitter enmity to Pope, who ridiculed him in the *Guardian* with his accustomed success. P. was a Whig, and after the accession of the House of Hanover held various lucrative posts, chiefly in Ireland. He died in London, June 8, 1749. P. received the nickname 'Nabby-Pamby,' from a peculiar short metre and puerility of diction which he frequently adopted. Johnson has kindly said of his productions that, if they have added nothing to English literature, they are at least worth reading. Besides the pieces mentioned, P. wrote a *Life of John Williams, Archbishop of York* (1700); a *Winter Piece*, a poem in the *Tatler*

(1709); the tragedies *The Distressed Mother* (1711); from the *Andromaque* of Racine; *The Briton* (1721); *Humphrey, Duke of Gloucester* (1721); and most of the political articles in the *Free-Thinker* (3 vols. 1718-19). See Johnson's *Lives of the Poets*.

Philistines (variously derived from the Heb. root *palash*, 'to migrate,' from *shepelah*, the name of the plain they inhabited, by transposition, or connected with *Pelasgi*), were a tribe or nation who occupied the southern part of the coast plain of Palestine, which later name of the Land of Canaan, indeed, is derived from that of their territory, *Philistia* or *Palestina*. The origin of the nation is wrapped in obscurity. They are described by the Hebrew prophets as from *Caphtor* (Amos ix. 7), and as 'the remnant of Caphtor' (Jer. xlvii. 4), while in Deut. ii. 23 the *Caphtorim* are said to have driven out the *Avim*, and occupied their territory. Again the *Philistim* are mentioned (Gen. x. 14) among the descendants of *Mizraim* (the Egyptians), while they are distinguished from the *Caphtorim*. An opinion held by some of the best modern critics is that by *Caphtor* is to be understood the island of Crete (cf. 1 Sam. xxx. 14; Ez. xxv. 16; Zeph. ii. 5). But even if this were settled, the antecedent question is still undecided as to whether they were of Semitic or Hamitic origin, coming from Egypt, or of an Aryan stock, from the other side.

The date of the first arrival of the P. in Canaan is also quite uncertain. They had already established themselves in the S., under a monarchy, in the time of Abraham (Gen. xx. xxi. xxvi.). At the time of the Exodus they were a warlike and formidable nation (Exod. xiii. 17), ruled by five princes or chiefs of five cities, Gaza, Ashdod, Eshkelon, Gath, and Ekron (Josh. xiii. 3). Their power about this time (B.C. 1500-1200) was so great that they were able to carry on war simultaneously with the Egyptians and the Sidonians, the latter of whom they forced to remove their capital to an island (Tyre). After the Israelites were settled in Canaan, between them and the P. there was kept up an almost incessant warfare, in which the latter seem upon the whole to have had the best of it, till the time of David, from whom they received such a check as stopped their inroads for a time (cf. 1 Kings iv. 21). That they were still powerful, however, appears from the fact that Solomon thought it necessary to build forts on the frontier (1 Kings ix. 17), and the intermittent warfare which continued under the kings of Judah and Israel (cf. 1 Kings xv. 27, xvi. 15; 2 Chron. xxi. 16, 17, xxvi. 6; Joel iii. 4-6; Amos i. 6-8; Is. xiv. 29-32). In the wars between Assyria and Egypt *Philistia* became the battle-field for the two powers (about 700 B.C.). The Assyrian general took Ashdod, which was only retaken (about B.C. 620) by the Egyptians under Psammetichus. Gaza, which had been taken by Pharaoh-Necho (B.C. 610-594), on his return from the battle of Megiddo (2 Kings xxiii. 29; 2 Chron. xxxv. 20), was retaken by Nebuchadnezzar (about B.C. 607), again taken by Pharaoh-Hophra (B.C. 589-570), and retaken by Nebuchadnezzar about the same time as Jerusalem (B.C. 588). During the Babylonian Captivity the P. sought to revenge themselves on their old enemies (Ez. xxv. 15-17), but a change took place after the return (B.C. 535), for the fraternising of the two nations was a scandal to the puritan Jews (Neh. xiii. 23-25). From this point the history of the P. is lost in that of the neighbouring nations.

The religion of the P. was a species of nature-worship. Their deities were Dagon (q. v.), worshipped chiefly at Gaza (Judges xvi. 21-23) and Ashdod (1 Sam. v. 3-5), Astarte at Ashkelon (1 Sam. xxxi. 10), and Baalzebub, at Ekron (2 Kings i. 2-6). The Dercero of Diod. Sic. ii. 4 is the Astarte of the Bible. See Ewald's *Geschichte des Volkes Israel* (vol. i. Eng. trans. 2d ed. 1869); Hitzig's *Urgeschichte und Mythologie der Philistiner* (Leips. 1845); *Zeitschrift der Deutschen Morgenl. Gesellschaft* (1848, 1860, 1862); Mover's *Phanizier* (3 vols. 1840-56).

Phillip, John, R.A., one of the most powerful of modern painters, born at Aberdeen, 22d May 1817, was apprenticed to a house-painter, and displayed an instinctive knowledge and command of colour almost in childhood; removed to London (1837) under the auspices of Lord Panmure, and studied at the Royal Academy. He exhibited his first historical picture in 1840, but returned to Aberdeen, where he resided till, his health failing him, he went to Spain in 1851, and from this period the character of his art, which had at first been specially Scotch—as exemplified in his 'Scotch Fair,' &c.—became changed, and

he afterwards painted chiefly Spanish subjects. His chief works are 'Life among the Gipsies at Seville' (1853), 'Letter Writer of Seville,' and 'El Paseo' (1854-55), 'Spanish Contrabandistas' (1858), the 'Marriage of the Princess Royal' (1860), and 'The House of Commons, 1860' (1863). The last two are difficult subjects, embracing numerous portraits, yet both are masterly in composition, and, like all P.'s works, rich and brilliant in colour, and especially powerful in drawing and in brush-work generally. P. was admitted Royal Academician in 1859, and died in London, 27th February 1867.

Phillips, Thomas, B.A., the successor of Fuseli as professor of painting in the Royal Academy, and an able lecturer and art critic, was born at Dudley, Warwickshire, in 1770, apprenticed to a glass-painter at Birmingham, and removed to London in 1790. He first exhibited in the Royal Academy a view of Windsor Castle (1792), became an associate in 1804, a full member in 1808, and professor of painting in 1824. Early in his career he painted classical and historical subjects, but afterwards found his true vocation in portrait-painting, in which, though a contemporary of Lawrence, he achieved much distinction. P. died 20th April 1845.

Phillips, Wendell, one of the most distinguished advocates of the abolition of slavery in America, is the son of John Phillips, the first Mayor of Boston, and was born at Boston, November 29, 1811. He was educated at Harvard College, where he graduated in 1831. He then entered the Cambridge Law School, and after remaining there for two years, was admitted to the Suffolk bar in 1834. But he soon gave up the study of law to throw himself heart and soul into the anti-slavery movement, which was then, under the powerful advocacy of William Lloyd Garrison (q. v.), beginning to agitate American society. He made his *début* as an orator in 1837, at a meeting held in Boston to protest against the murder of the Rev. E. P. Lovejoy, the editor of an anti-slavery newspaper in that town, who had fallen a victim to the fury of a mob; and from that time until the abolition of slavery (February 1, 1865), he was incessantly occupied in promoting the end to which he had devoted his life and his fortune. With a great amount of solid learning, P. united an oratory distinguished for its powerful logic, its pungent wit, and its rich variety of language. He spoke without notes, in a manner grave and dignified, using gesture seldom, but always with great effect. His countrymen consider him one of their most distinguished orators, and were ever ready to give him a crowded house, on whatever subject he was to speak. After the abolition of slavery, P. devoted himself chiefly to lecturing on temperance and women's rights; but he now seldom appears in public. He has published *The Constitution of a Pro-Slavery Compact* (1844); *Can Abolitionists Vote or take Office under the United States Constitution?* (1845); *Speeches* (1852); *Defence of the Anti-Slavery Movement* (1853); *Addresses on Slavery, Temperance, &c.* (1859); *Speeches, Lectures, and Letters*, 1853-63 (1863).

Phillipsburg, town of New Jersey, U.S., on the Delaware River, opposite Easton, 75 miles W.S.W. of New York by rail. It has large manufactures, chiefly of iron, and publishes a newspaper. Pop. (1870) 5932.

Phillour, a town in the district of Jullundhur, Punjab, British India, on the right bank of the Sutlej, 1110 miles N.W. of Calcutta by rail. Pop. (1868) 7535. There is an important fort here, guarding the passage of the Sutlej. At the time of the Mutiny of 1857 it contained the arsenal which fitted out the siege-train to operate against Delhi; on the first news of the outbreak, the fort was occupied by European troops, but the sepoys in the cantonments escaped to join the mutineers inside Delhi.

Philo-Judeus, to whom the later Jews have given the name of Jedediah, was a Jew of Alexandria, regarding whose personal history very little is known. The family to which he belonged were wealthy, and held in high estimation; for his brother Alexander was Alabarch or president of the Jews at Alexandria, a friend and banker to Agrippa, and donor of the gold and silver plating of nine of the doors of the temple at Jerusalem. P. himself was a man of such ability and high character, that he was chosen by his co-religionists to act as chief of a deputation of Jews who went to Rome (A.D. 39-40) to appeal to the Emperor Caligula regarding their persecution under Flaccus,

the Roman President, in connection with the emperor's insane demand that divine honours should be paid to him. As there is no record of the birth of P., it can only be conjectured from his own description of himself as 'a grey-headed old man' at the time of this embassy, of which he gives an account, that he had been about sixty years of age at the time, which would fix his birth about B.C. 20. There is abundant proof in his voluminous writings that P. was a man of great learning. Fully educated in all the doctrines, laws, and customs of his ancestors, he was an earnest student of Greek philosophy and the other branches of learning—grammar, geometry, music, poetry, &c.—which formed the intellectual atmosphere of Alexandria, at that time the metropolis of the learned world.

P. is the best representative of the philosophical tendencies of the Hellenistic Jews, who held the conviction that the Greek philosophers had derived their ideas from the Hebrew Scriptures, and especially from the Law of Moses. From this belief resulted the system of allegorical interpretation (see HERMENEUTICS), which was carried to such a pitch at Alexandria, and by none further than by P., according to whom Abraham, the father of his race, was the forerunner of all who believe in God, and Moses, the father of the law, the prophet, lawgiver, priest, and king, was the greatest of all men, who, by the abiding presence of the Spirit of God, attained to the supreme heights of wisdom. The other holy men of bygone days were only like disciples in comparison, and the greatest men among the Greeks learned from him. The Jewish nation was the first-born of the Creator, the priest and inspired prophet of other nations. But while making so much of Judaism as he does, Greek ideas filled a large place in his theology, which was founded on a combination of the Jewish, Platonic, and Neo-Platonic conceptions of God. The real nature of God cannot be defined or described. He has no qualities, and no name, except the four letters Jhvh, which mean pure Being. As to the world, it and all that exists were formed by God out of matter, but between God and his creation there existed an infinite distance. In seeking to bridge over this gulf P. found certain materials ready to his hand. In the Old Testament there was the notion of angels, as intermediate beings, of Wisdom, as a person helping at the creation (cf. Job xxviii.; Prov. i., iii., viii.), and of the Word of God, by which the light, &c., had been called into existence at the creation (Gen. i.). The conception of P. is that certain *forces* proceed from God, which he sometimes seems to describe as attributes of God, and sometimes as distinct beings, like the angels. The highest of the forces, which indeed comprises all the rest, is the divine Logos ('word'), which is both the spoken word and the thought of God; as the latter inseparable from God, but as the former the likeness of God, a second God, by whom the world was created, and is maintained and ruled. Otherwise expressed, the Logos is a manifestation of God, the ideas in which are imprinted on matter. In the world of Man, which is also created in the image of the Logos, spirit and matter war against each other. If man is to fulfil his destiny, the former must conquer and rule the latter, and in some this is accomplished by the perpetual influence of the Logos. The reform of morals consists mainly in deliverance from *matter*, from the flesh and lust. Forgiveness of sins is granted by God to all who believe, not for the world's sake, but of his own gracious nature. He serves those whom he knows to be worthy of healing, revealing himself to holy souls by his spirit, but also electing the pious before they are born.

Many parts of the doctrine of P. are still the subject of keen discussion. It is still debated by scholars, e.g., whether the Logos of P. was a person or not. The 'word of God' of the Old Testament was simply a periphrasis for Jehovah; but wisdom was distinctly personified. What P. did, then, was to identify the two, thereby making the Word a person; and what St. Paul and the author of the Fourth Gospel did was to identify the Logos with Jesus Christ. Again, the idea of P. that the world of matter and of humanity was a concrete expression of the Logos, who, as an ideal or type (the ideal world or archetype of Plato), impressed himself on matter as a signet ring, was developed, through the medium of the primitive Christian idea of a Messianic kingdom of God or of heaven, into the transcendent reality of heavenly things represented as the pattern of the present world in the Epistle to the Hebrews (cf. viii. 5; ix. 23). Another parallel between the New Testament and the writings of P., or between Christ and the Logos of P.,

is that the latter is regarded as a Mediator-Paraclete (*cf.* Heb. vii. 25, Delitzsch *Com.*). See P.'s *Works*, Glöser's *Geschichte des Urchristenthums* (1831), and P. *die Jud.-Alex. Theosophie*, Dähne's *Jud.-Alex. Religions-Philosophie* (1834), Ewald's *Geschichte des Volkes Israel* (vol. vi. 1868), J. G. Müller in Herzog's *Real-Encyclopädie*, Keim's *Geschichte Jesu von Nazara* (vol. i. Eng. trans. 1873), Kitto's *Cyclopædia of Bibl. Literature*, art. *Philosophy* (3d ed. Edinb. 1876).

Philology, Comparative, is a science dealing not with individual languages, but with the whole body of language, with rough-hewn speech rather than the polished gems of literature, with the rude jargons of a Bushman or Eskimo no less than with the Attic of Pericles or the Tuscan of Dante. It is a science partly historical and partly physical—historical because it traces the gradual evolution of human thought as recorded in language, physical because the articulate sounds through which that thought must find its utterance are subject to the restraints of physiological conditions. It is one of the youngest of the sciences, dating only from the opening years of the present century. The old Greek philosophers, dividing the whole world into Greeks and Barbarians, confined their inquiries to a single idiom—their own—and busied themselves with fruitless speculations on the origin of Language (q. v.). The first step on the pathway of linguistic knowledge was taken by the grammarians of Alexandria, who analysed the Greek language for the purpose of teaching it to the youth of Rome: to them we owe our present terminology. A far greater advance was brought about by the birth of Christianity, which broke down Gentile and Barbarian barriers, whilst its missionaries became the pioneers of philological research. Hervas (q. v.) compiled his *Catálogo* from vocabularies collected by himself and his brother Je-uirs; and translations of the *Paternoster* still furnish the philologist with some of his most valuable materials. But knowledge, to be scientific, must be comparative; and its standard of comparison must be correct, or the results arrived at will be worse than useless. As in the Ptolemaean system of astronomy the belief that the sun was the centre of the universe gave rise to countless misconceptions, so the quasi-religious notion that Hebrew must be the primitive language of mankind was for centuries the *ignis fatuus* of P. Leibnitz (q. v.) was the first to dispel the illusion, and apply the principles of induction to a subject that hitherto had only been treated empirically, pointing out the necessity of collecting the greatest possible number of facts, and reasoning from them, not from foregone conclusions. Fruits of the seed thus sown were the *Glossarium Comparativum Linguarum Totius Orbis* (1787) of Catherine of Russia, Hervas' *Catálogo* (1800), and Adelung's *Mithridates* (4 vols. 1806-17). Here Hebrew, Chaldee, Syriac, Arabic, Ethiopic, and Amharic are recognised as common members of a Semitic family; the affinities are indicated of Lapp, Finnic, and Hungarian; Basque is shown to be independent of Celtic; and Humboldt is anticipated in his announcement of a Malayo-Polynesian family of speech extending from Madagascar to the Easter Isles. Glimmerings even may be discerned in Hervas' work of the grand discovery which was to revolutionise the whole study of languages, and render possible a science of C. P.—the recognition, namely, of the affinities of Sanskrit (q. v.) with nearly all the languages of Europe. Fully to appreciate the vast importance of this revelation, let us conceive for a moment Latin to have been wholly lost and Provençal only recently discovered. What a flood of light would be thrown by the latter on the younger Romance dialects; how far clearer, for instance, could some such form as *semetipsum* be detected in the Prov. *smetessme* than in the more mutilated Fr. *même* or the Port. *mesmo*. Such, but in tenfold measure, was the importance of the discovery of Sanskrit. It is easy, at this interval of time and with our *ex post facto* knowledge, to say that its value has been over-estimated, or wonder at the crass stupidity of those who failed without its aid to discern the affinity of Celtic to Latin, or of the Teutonic to the Slavonic languages. The fact remains the same, that prior to the researches of Jones and Colebrooke these affinities had passed unheeded, nor is there anything to prove that they might not have so continued down to the present day. Again, were one of us suddenly to learn that he had an unknown first cousin living in the heart of Africa, would not his attention be instantly arrested; would he not set himself to trace out the relationship, and in so doing learn perhaps more about his kindred nearer

home than he had ever known before? Similarly, when once it was shown that the English Bible and the Sanskrit Vedas had common words for father and mother, for son and daughter, for brother and sister, for house, herds, the metals, numerals, and pronouns, then men naturally began to ask whether the same held good with Latin, Greek, and German; and close on Colebrooke's Sanskrit Grammar came the Comparative Grammar of Bopp (q. v.), in which the existence of that great family of languages variously known as Aryan (q. v.), as Indo-Germanic, or Indo-European, was established beyond a doubt. With the exception of Basque, Magyar, Turkish, and Finnish, all the languages of Europe, and Sanskrit and Zend, with their modern descendants, in Asia, were seen to stand to each other in the same relation as Gaelic to Welsh, and to a parent Aryan tongue as French and Italian to Latin.

The next problem submitted to C. P. was—Given the close relationship of the Aryan languages one to another, are they in any way connected with the other languages of the world? As French is closely akin to Italian, more distantly to Greek, may not the latter bear certain remote affinities with Hebrew, Turkish, or Chinese? Unity, according to Plato, is the end of science, as of philosophy, and philologists were naturally eager to extend the great family of speech so recently established. The merest glance at the grammar and vocabulary of Basque or Finnish would suffice to show that no such close connection could be looked for between these and Sanskrit as between Sanskrit and Zend, and that it would therefore be as much more difficult to prove any connection as in pedigree-making it is harder to trace the relationship, even when known to exist, between members of the sixth than between those of the second generation. At any rate, according to the canons of the newly-founded science, classification must precede comparison, and from such classification great results have undoubtedly been obtained, though tending it may be in a different direction to what was at first anticipated. Languages as widely separated as Sanskrit and English have shown themselves to be allied like them to one another, forming a third great family, the Ugro-Altaic or Turanian (q. v.), which embraces Lapp, Finnish, Mordvinian, Turkish-Tartar, Hungarian, Mongolian, Tungusian, and probably Accadian, Basque, and the Dravidian dialects. Chinese, on the other hand, stands in a class by itself, and can be brought into no immediate relationship with any other known language.

But how is Chinese *sui generis*? how does it differ from the Turanian languages, and these again from the Aryan? and must such differences be regarded as organic or accidental, as indicating independent beginnings, or compatible with a common origin of human speech? The answer to these three questions may best be sought in an examination of the theory put forward by those philologists who hold to the original unity of language, who see in Chinese, Turkish, and Sanskrit three stages of development—an Isolating or Monosyllabic stage, represented by Chinese; an Agglutinative or Combinatory, by Turkish; and an Inflectional or Amalgamating, by Sanskrit. Chinese has no grammar at all, in the ordinary sense of the term, *i. e.*, no inflections, declension, or conjugation; it makes no formal distinction between nouns, verbs, and adjectives, the various relations of a sentence being indicated by means either of particles or position. Thus 'with a stick' is expressed by *y ting* (lit. 'employ stick'), 'in the empire' by *kuo-cung* (lit. 'empire middle'), and 'men' by *jin-tu* (lit. 'man crowd,' *cf.* Eng. *mankind*), whilst *ngo ta ni* means 'I beat thee,' and *ni ta ngo* 'thou beatest me.' But though theoretically each word in Chinese is monosyllabic and independent, Chinese grammarians can draw a clear distinction between 'full' and 'empty' words—those, namely, that are used with their *bona fide* signification of noun or verb, and those that are simply employed as particles, and of the latter some have wholly lost their former independent character. *Chao*, for example, in *wo-chao*, 'we' (lit. 'I company'), is no longer used separately, but only as a symbol of plurality. In the second or Agglutinative stage, words not only become empty, but simple suffixes, ground down by the wear and tear of time to single letters, or sometimes even wholly disappearing. The full word or theme, however, admits not the slightest change, its individuality always remains intact. For instance, in Turkish, from the abstract root *sew*, 'love,' is formed the present *sever-im*, *sever-sen*, *sever*, *sever-iz*, *sever-siz*, *sever-ler*, where *sen*, 'thou,' and *siz*, 'ye,' present an uncorrupted, and *im*, *in*, and *ler* a corrupted form, whilst the third person ending has dropped wholly out of use.

Similarly through an almost endless variety of moods and tenses, through all the declensions of nouns or pronouns, a root always remains the same in Turkish, which could tolerate the Sansk. *as-mi*, but hardly the Lat. *sum*, whilst *lay* as the perfect of *lie*, or *kine* as the plural of *cow* would be utterly repugnant to its genius. Violations, however, of the general rule are to be met with in members of the Turanian family, e.g., the Finnish plural *käsi*, from *kädet*, 'a hand,' and the Tamil plural *karkal*, from *kāl*, 'a stone.' Lastly, the distinction between Agglutinative and Inflectional languages lies chiefly in the fact that the former, retaining the consciousness of their full words, preserve these at least from decay, whilst in the latter, to quote Max Müller, 'the various elements which enter into the composition of words may become so welded together, and suffer so much from phonetic corruption, that none but the educated would be aware of an original distinction between root and termination, and none but the comparative grammarian be able to discover the seams that separate the component parts.' Not that this distinction is always complete and sharply marked. Just as in Chinese we come upon incipient traces of agglutination, and in Finnish of inflection, so in English we find forms such as *truth-ful* and *horse-man* which would not ring strange in Chinese ears, or as *mun-hood* (Old Eng. *hād*, 'state') and *word-lock* (Goth. *lāiks*, 'sport') which might form part of a Turanian vocabulary. But, on the other hand, neither Turk nor Chinaman could for an instant understand how the past tense of *throw* could be expressed by *threw*, of *capio* by *cepi*, or how a plural *mice* could be formed from a singular *mouse*. True, say the advocates of the theory we are now considering, but then change is admittedly the law of every living language. The *Bébé* has lost its meaning for the Englishman of to-day, Cicero's *Philippics* for the Parisian, and the *Zend-Avesta* for the modern Persian. Yet English, French, and Persian can trace an unbroken descent from the languages in which those works were written; their present form is the work of two gradual but ceaseless processes—Phonetic Decay and Dialectic Regeneration. The desire to save time and trouble, to do everything with the least expenditure of energy, has caused us to drop or change the difficult guttural sounds of *high* and *laugh*; has worn away *utaticum* to *age*; and in Bohemian has reduced the parent-Aryan *duhitā* ('daughter,' 'milkmaid') to *di*. It has also lessened the tax upon the speaker's memory by sweeping away a host of so-called irregularities, and substituting for them forms based on analogy—giving *sept* for the older *seis*, in Italian conjugating all verbs as though they belonged to the first conjugation, and in modern Greek making every nominative terminate in *s*, as *pateras* for *pater* and *geras* for *geron*. Were phonetic decay the only principle at work, languages would in the lapse of ages be worn away almost to nothing. If all the obsolete phrases, words, and inflections were struck out from Wyclif's Bible, and no new ones substituted in their stead, the residuum would indeed be small, and its meaning hard to discover. How poorly would the Romance languages fare had they no words to represent the obsolete Lat. *equus* and *ignis*, no mode of expressing futurity, or nothing to supply the loss of the case-endings. But, as a matter of fact, we find that new words, drawn from the treasure-house of dialects, and cast perhaps in a fresh mould, replace those that have been lost or obliterated, and that when broken-down inflections no longer suffice, men analyse their concepts anew, resolving *amabo* (*ama-fuo*) into *amerei* (*amare habeo*) and *dulcius* into *magis* or *plus dulce*. The use of language is the communication of knowledge; accordingly, with every fresh extension of knowledge, whether in the field of art, science, or philosophy, language is called upon to express the new ideas, to supply the botanist and geologist with a nomenclature, and give new names to new inventions like printing or telegraphy—new in the sense of being reapplied or reconstructed, but whose elements are only less ancient than the metals with which we construct the latest improved machinery. Conversely, when any branch of knowledge falls into disuse, its terms grow burdensome and superfluous; men cease to remember the language of the *futurer*, the alchemist or the astrologer. Besides these gradual and internal changes, languages may be powerfully influenced from without, either by conquest or by the accidents of social intercourse. Thus Celtic gave place to Latin in Gaul, and to English in Britain, whilst English in turn, though holding its own against Norman-French, lost nearly all its original inflections and incorporated in its vocabulary a vast number of Romance words. Grammars, however, say some of our greatest

philologists, are never mixed, a statement which, if generally true, is false at least of the Romani or Gypsy dialects. The Welsh gypsies have preserved their ancient inflections almost intact, as *java*, 'I go' (*jama*, 'go I'), and *ghiom*, 'I went' (*ghilo-hom*, 'gone am I'); their brethren of north-west England mix English and Romani forms in nearly equal proportions, retaining *java*, but substituting *mi jawed* for *ghiom*; whilst in the dialect of the southern counties all vestiges of the old case and verb endings have wholly disappeared.

Therefore, as under the action of these various changes, French has been developed from Latin, Persian from Zend, and both Zend and Latin from a parent-Aryan speech, so, it is argued, inflectional languages may once have been agglutinative, agglutinative languages isolating, and in isolation may be seen the primeval type of human speech. The theory is plausible and attractive, but it is only a theory, and one that with wider knowledge may prove as baseless as his who, observing the universal transition from infancy to manhood, should infer that an Ethiopian had power to change his skin. The following are some of the principal objections raised against it by Pott and Sayce:—If the three stages of mental development imply mental progress, how comes it to pass that the highly-cultured Chinese stopped short at the first stage, and the Turanian races at the second; or that they have never improved on their own inferior systems, though brought into contact with Aryan Buddhism and European influences? In agglutinative languages the sign of the plural precedes the case-endings, in the Aryan it follows them—a difference explainable by no amount of phonetic decay. An analysis of Aryan inflections points to a system of pronominal roots, of which no trace is to be found in the agglutinative family. And, lastly, the theory does not take into consideration those forms of speech which do not fall strictly under one of the three heads, the polysynthetic languages of America, for example, in which the sentence is fused into a one long compound; nor account for the fact that, whilst Aryan roots are verbal and monosyllabic, Semitic and Turanian roots are both verbal and nominal, both monosyllabic and polysyllabic. Not until these objections have been met, shall we be able to proceed to a philosophic investigation of the unity of speech. But it is worth perhaps indicating that such unity would by no means, as is so frequently assumed, be necessarily identical with the original unity of the human race. For, allowing mankind to be descended from a single pair of ancestors, languages may not have been originated till long after those ancestors had passed away; and, similar causes producing similar effects, and man possessing like impulses and desires the whole world over, the first efforts at articulation may have been as manifold as are the notes of all the various species of birds. The earliest revelations of Semitic speech point at least to the northern deserts of Arabia, and those of the Aryan language to the Hindu Kush. Or, on the other hand, supposing the negro and the European to have come of distinct stocks, the latter might have been the first to develop the latent faculty of speech, and the negro might have caught the idea from him. These are some of the hypotheses, the 'might-have-beens' of philology, serving to illustrate the need of working backwards from existing facts, and of always combining abstract speculation with historical research, whilst bearing constantly in mind the shifting influences on language of pastoral or nomadic life, of increased culture, or of a standard literature. The art historian can only show the points of contact and divergence between the Italian and Flemish schools of painting by the external and internal evidence at his disposal; were he on abstract principles to argue that all art must of necessity spring from a common centre, and support his argument by chance coincidences between the design of an Egyptian mummy-case and of a painting by Raffael, he would obviously be travelling beyond his legitimate province; the results of his speculations could only excite a smile. Facts must be the arbiters between Professor Whitney and Mr. Sayce, when the former asserts dogmatically that 'Indo-European language, with all its fulness and inflective suppleness, is descended from an original monosyllabic tongue'; whilst the latter, with scarcely less appearance of authority, maintains that 'languages at first were infinitely numerous and diversified; . . . they have gradually diminished and disappeared through the course of ages by a long process of natural selection.' Whether Mr. Sayce is right in his conclusion, as we incline to hold, or whether the upholders of the homogeneity of language will ultimately triumph, time and further investigations alone can defi-

nately show. But in the meanwhile there must be no formulating of hypotheses as laws, or reasoning from foregone conclusions which after all may turn out as idle as that which made Hebrew the mother of all the dialects of Babel.

Philomela, in Greek mythology, a daughter of King Pandion in Attica, who, being dishonoured by her brother-in-law Tereus, was metamorphosed into a nightingale, which bird was ever afterwards called by her name.

Philopœmen, a patriotic Achæan general born at Megalopolis in Arcadia, about 252 B.C., was educated by a citizen of Mantinea called Cleander. His name first occurs in history in 222, when Megalopolis was taken by Cleomenes; and in the following year he distinguished himself at the battle of Sellasia. Next he served in Crete for some years. In 210 he obtained command of the Achæan cavalry, and in 208 he became head of the league. In this position he defeated Nabis about 207. He again sailed for Crete, and returned in 194, routing Nabis a second time in 192. In 188 he took Sparta, treating it with great severity, razing the walls of the city to the ground, and forcing the Achæan laws upon its citizens. In 183 he was captured by a body of Messenian troops, carried to Messene, and forced by Democritus to drink poison. His ashes were brought to Megalopolis by Polybius the historian, amid a procession of great magnificence. See *Plutarch's Lives*.

Philosophy is the universal science aiming at an explanation of all phenomena of the universe by ultimate causes. The name seems to have been coined by Pythagoras, who, unwilling to assume the title of 'wise' (*sophos*) which had been accorded to earlier sages, called himself a 'lover of wisdom' (*philos sophias*). In this modest sense Socrates also used the term *P.*; but it quickly became synonymous with wisdom (*sophia*). The Romans used the word *sapientia* until the time of Cicero, when *philosophia* was imported. The history of *P.*, which, while special sciences study God, and nature, and man, aims at a common explanation of all three, may be epitomised in the definitions of it given by the most celebrated thinkers. The principal are these:—'Knowledge of things divine and human' (Pythagoras); 'Acquisition of true knowledge; a resembling of the Deity in so far as that is possible to man' (Plato); 'Art of arts, science of sciences, the science of being, as being' (Aristotle); 'a striving after virtue in the sciences, physics, ethics, and logic' (Stoics); 'Rational pursuit of happiness' (Epicurus). The modern definitions of *P.* are:—'The science of things, evidently deducible from first principles' (Descartes); 'Science of effects by their causes, and of causes by their effects' (Hobbes); 'Science of sufficient reasons' (Leibniz); 'Science of things possible, in so far as they are possible' (Wolff); 'Science of the connecting principles of nature' (Adam Smith); 'Science of truths, sensible and abstract' (Condillac); 'Science of the relations of all knowledge to the necessary ends of human reason' (Kant); 'Science of the original form of the Ego, or mental self' (Krug and Fichte); 'Transformation of the notions of experience' (Herbart); 'Science of the absolute, or of the absolute indifference of the ideal and real' (Schelling); 'Science of reason, in so far as the latter is the conscious idea of universal being in its necessary development' (Hegel); 'Knowledge of effects as dependent on their causes' (Hamilton); 'Attainment of truth by the way of reason; substitution of true ideas, that is, of necessary truths of reason, in place of oversight of popular opinion' (Fénelon). See under such heads as Dualism, Ethics, God, Idea, Matter, Metaphysics, Nominalism, Perception, Reason, Scepticism, Soul, Space, Time.

Philosophy. Moral. See **ETHICS**.

Philostatus, the name of a distinguished Lemnian family of which the most celebrated was **Flavius P.**, born about 182

A.D. He studied and taught at Athens (whence he is called 'the Athenian'), and afterwards removed to Rome, where he was introduced to the literary circle of which Julia Domna, wife of the Emperor Severus, was the centre. *P.* was alive in the reign of the Emperor Philip (244-249). The following are the extant works of *P.*:—*Ta eis ton Tyanea Apollonion*, in eight books; *Bioi Sophiston*, in two books, a history of the Sophists from Gorgias to his own time; *Hērōika* or *Hērōikos*, a dialogue concerning the heroes of the Trojan war; *Eikones*, in two books, an account of various paintings, showing great richness of fancy, and written in a pleasing style; and 73 *Epistolai*, chiefly of an amatory character. The best edition of *P.*'s works is by Kayser (Zur. 1844).—*P.*, the younger, usually called **The Lemnian**, grandson of the former, taught at Athens, died at Imbros, and wrote, in imitation of his grandfather, a work called *Eikones*, a portion of which still exists.

Philpotts, Henry, D.D., born at Bridgewater in Somersetshire, May 6, 1778, passed from the College School, Gloucester, to Corpus Christi College, Oxford, graduated B.A. (1793), and was elected a fellow of Magdalen. He became chaplain to the Bishop of Durham (1806), prebendary of Durham (1809), rector of Stanhope (1819), Dean of Chester (1828), and Bishop of Exeter (1830). A strong High Churchman, he was the originator of the Gorham Controversy (q. v.), whilst in Parliament he signalled himself by his bitter eloquence against the Reform Bill, the Ecclesiastical Commission, and other Liberal measures. He died at Torquay, September 18, 1869.

Phil'ter, or **Phil'tre** (Gr. *philtion*, 'a love charm or potion'), the name given by the Greeks and Romans to various drugs or preparations possessing the virtue of exciting love, the recipe for which has not come down to our time. Madness and death were frequently caused by the administration of powerful potions of this kind. The Thessalian philtres were notorious in Juvenal's time.

Phlebitis, or **Inflammation of the Veins** (Gr. *phlebs*, 'a vein'), consists, in some measure at least, of diffuse inflammation spreading along the cellular membrane in which the vein lies, the anatomical characters being perceived partly on the cellular tissue which supports the vein, partly on the coats of the vessel and partly in its contents. The leading symptoms of *P.* are hardness along the course of the vein caused by coagulation of the contents, pain, redness, and some amount of general fever. Such passive coagulation used to be called *adhesive P.* on the supposition that it was caused by effusion of lymph from the lining membrane of the vein; but in many cases there is no evidence of any inflammation, and it has been shown that the lining membrane of the veins does not secrete lymph. The condition is now called *thrombosis*, depending upon pressure or obstruction to the return of blood, from diminished power of the circulation from the varicosity of the veins, from clots of blood being lodged in the veins, and from conditions of the blood itself which are as yet but imperfectly understood. In the thrombosis which occurs in the disease called *phlegmaria dolens* the coagulation takes place in the uterine sinuses and extends down the iliac, femoral, and other veins. Sometimes the veins become blocked, to a very great extent, in consequence of some condition of general disease though without any definite local exciting cause. The varieties of *P.* are enumerated by Mr. Paget as follows: (1) the traumatic, including those due to distension; (2) those occurring in exhaustion, during or after either acute or chronic disease; (3) those due to extension of inflammation, or of blood-clotting from ulcers, morbid growths, or gangrenous or acutely inflamed parts; (4) those of the so-called idiopathic or rheumatic form; (5) the pyæmic; (6) the puerperal (among which it is probable that examples of all kinds, only modified by the puerperal state are grouped); and (7) the gouty.

The treatment of *P.* is merely expectant, the constitutional or general disorder being treated according to its own indications. Perfect rest is necessary, and the part should be put in a position to favour the return of blood; warm lotions are grateful and reduce the pain arising from tension. When there is much diffuse inflammation, incisions around the affected vein may be necessary. Pain must be allayed by opium, and alkalis should be administered in rheumatic and gouty cases. See *Clinical Lectures*, by Sir James Paget, and *Practical Pathology*, 3d ed. by Mr. Lee.

Phlebotolithes (Gr. *phlebs*, 'a vein,' and *lithos*, 'a stone'), are small chalky concretions found in the cavity of the veins, and such concretions are occasionally recognised during life in the spermatic veins. P. are formed from the degeneration of clots, and consist of phosphate of lime, with some sulphate of potash and sulphate of lime, intermixed with protein substances from the blood.

Phlebotomy. See BLOOD-LETTING.

Phleg'ethon (Gr. 'flaming'), in the later Greek mythology, was a river of the lower world, whose waves were of fire instead of water, whence it was also named *Pyrphlegethon* (from *pyr*, 'fire'). Like the *Cocytus*, it flowed into the *Acherusian Lake*.

Phlegmasia Dolens, a disease almost peculiar to the puerperal state, is variously called *milk-leg*, *edema dolens*, *edema lacteum*, *dépôt du lait*, *metastasis lactis*, and *crural phlebitis*. It is properly a puerperal disease, and generally occurs between the end of the first and fourth weeks after delivery. P. D. attacks one extremity only at the commencement; but the other occasionally becomes affected subsequently, the left being more frequently attacked than the right. It generally occurs in those of broken-down constitutions, or who have suffered from debilitating discharges, as from profuse uterine hæmorrhage before or after delivery. P. D. is marked by a general and diffused swelling attacking the lower extremity, hard and elastic to the touch, and is attended with extreme pain, which is increased by movement or pressure. The swelling does not pit on pressure, the surface is glossy and white, the temperature high, and from a puncture or incision only a few drops of viscid serum exude which readily coagulates. P. D. is of uncertain duration, from a few weeks to many months or even years, and the acute symptoms may subside though the limb continues more or less swollen. A fatal termination is comparatively rare, but the patient may sink under the febrile paroxysm, or from debility, suppuration, or gangrene in the affected limb or other parts.—The treatment of P. D. consists in early evacuations from the bowels, sedatives, and medicinal agents to act on the liver, kidneys, and skin. The limb should be wrapped in a fold of new flannel, and the whole enveloped in oiled silk. Warm anodyne fomentations, or a tepid spirituous lotion, may be useful, and the early application of leeches to the hypogastrium, the groin, and the upper part of the thigh, have been recommended. In the chronic stage, frictions, with or without stimulant embrocations, and a properly adapted bandage, are of essential service.

Phle'um. See TIMOTHY GRASS.

Phlogiston (Gr. 'what burns, from *phlegrein*, 'to burn'), an imaginary principle of fire, invented by Stahl and his school to account for the phenomena of combustion. Thus lead when calcined is oxidised, and becomes the oxide. On the P. theory, this was explained by saying that during calcination lead lost P., and so became the calx or oxide of lead. Again, by heating the calx with a substance rich in P. (carbon, for instance), P. is absorbed and the metal results. The theory was completely disproved by Lavoisier, who established the modern system of chemistry.

Phlox is a genus of showy herbaceous N. American plants, belonging to the natural order *Polemoniaceæ*, of which a number of species have long been garden favourites. The flowers usually vary in shades of blue and red, whilst some are white and others variegated. Most of the species are perennial, but *P. Drummondii* is an annual, and is one of the most popular.

Phlyctenæ or **Phlyctenulæ**, are semitransparent vesicles, filled with watery fluid, which occur during humid mortification, and frequently on the edges of the eyelids, especially at the inner canthus, sometimes single, often in groups, varying in size from a mustard seed to a pea.

Pho'ca. See SEAL.

Phocæ'na. See PORPOISE.

Pho'cas, a common centurion of Cappadocian birth, in 602 was raised by the faction of the Greens to the throne of Constantinople, on which he sought to secure himself by the murder of his predecessor *Mauricius*, his sons, and principal adherents. But *Khosru II.*, the Persian Shah, refused to recognise the

usurpation, and opened a campaign, that lasted more than twenty years, by the reduction of Merdin, Dara, Amida, and Edessa. At home the insurrections of *Narses*, the Persian general, and of the widowed Empress *Constantine*, were quenched in blood; the former being burnt alive in the market-place of Constantinople, and the latter beheaded at Chalcedon. But an insult put upon P.'s own son-in-law, the patrician *Crispus*, led to an intrigue with *Heraclius*, the Exarch of Africa, and suddenly the Emperor beheld the African fleet, commanded by the younger *Heraclius* (q. v.), steering through the Propontis. The Greens were easily bribed to desert their fallen master, who, after suffering every species of contumely and torture, was finally beheaded, October 4, 610. Hideous and deformed, a lustful, drunken savage, P. forsook the soldier's trade without assuming the duties of a prince. His reign, says *Gibbon*, 'afflicted Europe with ignominious peace, and Asia with desolating war.' See *Gibbon's Decline and Fall*, ch. xlvii.

Pho'cidæ. See SEAL.

Pho'cion (Gr. *Phokion*), a celebrated Athenian general and statesman, and for a number of years the chief political opponent of *Demosthenes*, was born of poor parents at Athens about 402 B.C. After having been educated by *Plato* and *Xenocrates*, he entered upon his military career under *Chabrias*, and first gained distinction in the sea-battle at *Naxos* (376), where he commanded part of the Athenian fleet, and by his courage and skill greatly contributed to the victory. About 354 he led an expedition to *Eubœa*, and although betrayed by the *Eretrians*, who had called him to their assistance, he maintained a successful struggle against forces immensely superior to his own, and gained a signal victory over *Callias* of *Chalcis* at *Tamynæ*. In 341 he saved *Megara*, which a powerful party wished to deliver into the hands of *Philip* of *Macedonia*. In 340 he rendered a still more signal service to the Athenian state by forcing *Philip* to raise the siege of *Byzantium* and *Perinthus*, and by clearing the *Hellespont* of *Macedonian* cruisers. Notwithstanding these successes, however, P. was far from believing that his country was able to combat the growing power of her rival, and he continued to lend all his influence towards the maintenance of peace, and to bringing about a better understanding between *Athens* and *Macedonia*. He thus won the friendship of *Alexander*, and after the destruction of *Thebes* by the latter (B.C. 335), was able to gain easier terms for the conquered city, and to prevent the banishment of several of its patriotic defenders. He greatly offended the Athenians, however, by advising them to comply with *Alexander's* demand for the surrender of *Demosthenes* and the other leaders of the anti-Macedonian party. After the death of *Alexander*, when the Athenians prepared to renew the struggle for their independence, P. tried in vain to dissuade them, and after the united Greek forces had been defeated by the *Macedonians* at *Cranon* (322), leaving *Athens* at the mercy of *Antipater*, he became again mediator between the victor and the vanquished. But instead of gaining thereby the gratitude of his countrymen, he became the object of their hatred and persecution. Accused of treason, he fled with some friends to *Phocis*, where he sought refuge with *Polysperchon*. The latter, however, delivered him up as a peace-offering to the Athenians, by whom he was condemned to drink the hemlock. He perished in 317 B.C., at the age of eighty-five. His fickle countrymen soon afterwards repented of their conduct, and raised a brazen statue to his memory, at the same time condemning his accuser *Agnonides* to death. The private character of P. presents a noble example of unselfishness, and strict, if somewhat austere, integrity. But he did an irreparable wrong to his country by opposing the efforts of *Demosthenes*; and by unconsciously lending the weight of his name to the manoeuvres of those Athenian orators who were in the pay of *Philip*, he must be considered as having mainly contributed to destroy the independence of *Athens*. See *Plutarch's Lives*.

Pho'cis, a country in Northern Greece, bounded N. by the *Locri Epiconemidii* and *Opuntii*, W. by the *Locri Ozolæ* and *Doris*, S. by the *Gulf of Corinth*, and E. by *Boeotia*. Mountainous and barren, except on the *Crissæan plain* in the S.W., and in the valley of the river *Cephissus*, it owed its importance to its possessing the oracle of *Delphi*. *Mount Parnassus* rose in the interior of P.; other noted mountains were *Helicon* in the S.E., *Cirphis* in the S., and *Cnemis* in the N. Till the time of

Philip II. of Macedon, P. had little part in the history of Hellas. It then became merged in a war, called the Phocian or Sacred War, which engaged the chief states of Hellas, and cost P. its independence. The Phocians having tilled a part of the Crissaean plain, which the Amphictyonic Council had decreed (585 B.C.) should be waste for ever, the Thebans, who had long been hostile, persuaded the council to impose a fine upon the Phocians, and, on their refusal to pay it, to declare the Phocian land forfeited to the Delphian god. The Phocians seized the treasures of Delphi (357), and with them carried on the war that was waged for the next ten years. The Amphictyons and Thebans, failing to overpower the Phocians and their allies, called in the aid of Philip, who put an end to the war in 346. All the towns of the Phocians were now razed to the ground, with the exception of Abæ, their inhabitants dispersed by fifties in scattered villages, and their two votes in the Amphictyonic Council handed over to Philip.

Phœbus (Gr. *Phoibos*, 'the bright' or 'shining'), is used by Homer as an epithet of Apollo, to signify the purity and radiant beauty of youth. At a later period, when Apollo became identified with the sun (Helios), the name P. was applied to him as the sun-god.

Phœnicia (variously derived from Gr. *phoinix*, 'palm tree,' from *phoinos*, 'purple,' in reference to the dye which was one of the principal articles of its commerce, to the sun-burnt complexion of the inhabitants, or to the Red (Erythrean) Sea, from which, according to Herodotus, they emigrated; from Phoenix, the brother of Cadmus and son of Agenor; &c.) was the name given by the Greeks to the country lying between the Mediterranean Sea and the mountains of Lebanon, and very indefinitely (or variously at different times) bounded by Syria on the N. and Palestine on the S. The native name was Kanaan (Canaan), but as the Phœnicians or Zidonians were the most powerful of the Canaanitish tribes at the time of the arrival of the Hebrews in Palestine (*cf.* Gen. x. 15; Josh. xi. 8), their territory gave its name to the whole country, just as that of the Philistines gave it the later name of Palestina (Philistia).

Geography.—P. proper was only about 28 miles long (varying from one to five miles broad), or little more than what was sufficient to include the two cities of Tyre (q. v.) and Zidon (q. v.), which were about 20 miles apart: Tyre in lat. 33° 17' N., and Zidon 33° 34'; Zarephath lying between the two, about 8 miles S. of Zidon. But at a later period the name was applied to a district extending from the same point in the S., along the coast a distance of about 120 miles, not exceeding about 20 in breadth at any part. In this larger P. the first town to the N. of Zidon, at a distance of 16 miles, was Berytus (mod. *Beirut*, q. v.). Next to Berytus was Byblos (q. v.), the Gebal of the Bible (Ez. xxvii. 9), then Tripolis (q. v.), and lastly, near the northern extremity, Aradus, the Arvad of the Bible (Gen. x. 18, Ez. xxvii. 8), situated, like Tyre, on an island, opposite which was a small town on the mainland called Antaradus. By some authorities P. is made to extend some distance along the coast to the S., so as to include Acco (Acre, Ptolemais, q. v.) and even (which can hardly be warrantable) Joppa (q. v.), the port of communication between P. and Jerusalem. P. was extremely fertile, being composed for the most part of cross valleys formed by streams descending from the mountains on the E. Of these streams the chief were the Kasiniich (perhaps the same as the Leontes, mod. *El Litani*), five miles N. of Tyre; the Bostienus, N. of Zidon; the Lycus (mod. *Kelbi*), N. of Berytus; the Aionis (mod. *Ibrahim*), five miles S. of Byblos; and the Eleutherus (mod. *Kelbi*), between Tripolis and Antaradus.

Race.—Regarding the origin of the nation little can be known with certainty, but all existing evidence goes to prove that the highly civilised nationality which was already constituted in the time of Abraham was of the same race as the Canaanites. (1) We have seen that it was their territory to which the name of Canaan, given by the Hebrews to the whole of Palestine, properly belonged; so that they were actually the Canaanites, which, as appears from their coins, was the name the Phœnicians gave to themselves, being retained by the Carthaginians even in the 5th c. A.D., as testified by Augustine (*Expos. Ep. ad Rom.*). (2) This is confirmed by Gen. x. 15, according to which Zidon was the first-born of Canaan, which probably means that from time immemorial Zidon had been the greatest Canaanite power, and by Obadiah 20, which includes the P. among the Canaanites.

Trade and Manufactures.—A graphic account is given in the Bible of the general relations that existed between P. and Palestine. P. had many valuable natural products of her own, *e.g.*, the unlimited supply of timber on the Lebanon mountains, marble, &c., while her markets were supplied with the products of almost every country of the known world; which, as well as her skilled artisans, would all be in demand in Palestine. And the latter country, again, was the granary of P., from which were exported to it wheat, barley, honey, oil, wine, and balm (Ez. xxvii. *cf.* 2 Sam. v. 11; 1 Chron. xxii. 4; 1 Kings v. vii. 13, 14; 2 Chron. ii.). In the time of Solomon, if not in that of David as well (*cf.* 1 Chron. xxii. 4), a distinct alliance of mutual accommodation was formed between the two nations, and a common trade carried on by them for a time on the Red Sea (1 Kings ix. 26-28). A remarkable departure from these friendly relations on the part of the Phœnicians is alluded to by the prophets Joel (iii. 4) and Amos (i. 9), who speak of their selling as slaves captive Israelites, who had been taken in war by their enemies and sold to the Phœnicians. But the trade with Palestine was but a small part of the commerce of P. It formed, greatly owing to its geographical position, the link between the East and the West, and by means of its countless traders, held in its hands for a time the exchange of the whole civilised world. From the shores of the Euxine were brought copper, lead, and slaves; from Armenia, horses and mules; from Damascus and Babylon, wine; from Arabia, India, and the E. of Africa, gold, precious stones, spices, aromatic gums, ivory, ebony, &c.; from Egypt, as well as Palestine, wheat; from Egypt and Babylon, linen, woollen, and embroidered goods; from the N. of Africa, skins of wild beasts, cattle, &c.; from Spain and the Scilly Islands, silver, iron, lead, and tin; from Greece, pottery and the purple dye so well known in connection with the Tyrians. All these articles, raw or manufactured, were exchanged for each other in the marts of P., or by Phœnician traders.

The skill of the Phœnicians in manufactures, as well as in mining and navigation, was considerable. The purple dye which they imported at first from Peloponnesus they afterwards learned to extract for themselves from fish found on their own coast; and, according to Strabo, Tyre was unpleasant to live in on account of its numerous dye-works. They carried to a great pitch of excellence the manufacture of Glass (q. v.), which Pliny says was accidentally discovered on the shore of P., but which was probably derived from Egypt. They were also famed for their skill, not only in architecture, but in the manufacture of beautiful vessels and ornaments in gold, silver, ivory, ebony, &c. (*cf.* 1 Kings v. vii. 13, 14; Homer, *Il.* xxiii. 743, *Od.* iv. 618).

Colonies.—A system of colonisation was carried on by the Phœnicians almost co-extensive with their trade, settlements being formed at almost every point where their commerce was established. Either as mere commercial depôts, or as more permanent colonies and cities, they had settlements in Cyprus, Cethium, Rhodes, Crete, the Cycladic and Sporadic Islands, Cilicia, Lycia, and Caria; in Chios, Samos, Tenedos, Bithynia, the coast of the Euxine, Samothrace, Lemnos, Thasos, Boeotia, and Eubœa; in Sicily, Malta, Sardinia, and the Balearic Islands; in Spain, at Cadiz, Malaga, Belon, Abdarach; probably in Cornwall and the Scilly Islands, and even on the Baltic; on the N. coast of Africa, at Hippo, Carthage, Utica, Leptis, Hadrumetum, and on the N.W. at Mauritania and Lerne. Probably they had a settlement at Ophir (q. v.), wherever that may have been.

Religion.—The religion of the Phœnicians, like that of the Philistines, to which it was closely allied, as it was in fact to that of all the other Semitic tribes, was a species of nature-worship. The powers of nature—the sun, moon, planets, and the elements—were worshipped as male—Baal (q. v.), Moloch (q. v.), Dagon (q. v.)—or female—Baalus, Astarte (q. v.)—according as they were regarded in their destructive or their productive aspect. Besides the above deities, who were known by a number of other names expressing their different attributes, there were a number of minor ones, worshipped especially as the patrons of the seafaring class, notably Esmun (Esculapius), and a number of infernal deities. A number of natural phenomena, personal attributes, abstract ideas, seasons, trades, professions, and animals, were also deified: the last either as sacred themselves or as symbols, *e.g.*, the serpent, bull, lion, ass, dog, fishes, doves, goat, &c.

Language and Literature.—Regarding the language of the Phœnicians, the conclusion arrived at by scholars is that it was the same as the language of Canaan, which was adopted by the Hebrews (see *Jews: Language and Literature*); in other words, that it was Semitic, and of the three branches of that language—the Aramaic, Arabic, and Hebrew—was so closely allied to the last, that the two may practically be regarded as two dialects of one language. This conclusion is favoured (1) by the name Canaan, which was not merely a Hebrew translation of the native name, but, while it is a Hebrew word signifying 'low-land' (from the Heb. root *cana*, 'to kneel, be low,' cf. *Is. xxiii. 13*; *Zeph. ii. 5*), was actually the native name, as is proved by Phœnician coins. (2) The Hebrew is called the language of Canaan in the Bible (*Is. xix. 18*). (3) All the fragments of the Phœnician language which have been preserved have a remarkable affinity with Hebrew: (a) The names of persons and places in Canaan when the Hebrews arrived, which have been preserved in the Bible, are Hebrew, e.g., Abimelech (Heb. 'father-king'), Melchizedek (Heb. 'king of righteousness'), Kirjath-sepher (Heb. 'city of the book'). (b) The inscriptions on Phœnician coins and stone monuments, of which a large number have been found in modern times, correspond very closely with Hebrew. (c) Both Jerome (q. v.) and Augustine (q. v.) expressly mention that in their time (4th c. A.D.) there was a great similarity between Hebrew and the Carthaginian or Punic language, which was Phœnician, but no doubt corrupted with African and Latin words and idioms. (d) This last testimony is confirmed by a passage in the *Panulus* (v. 1) of Plautus, given, along with a Latin translation, as the speech in the Punic language of Hanno, and which can be partially read as Hebrew, so as to give a corresponding meaning. (e) Many Phœnician and Punic names of persons and places, well known in a Greek or Latin form, but unintelligible or with fanciful meanings in these languages, can have their meaning opened at once with the key of Hebrew; e.g., Zidon (Heb. *tzidon*, 'fishery'), Tyre (Heb. *tzor*, 'cliffs'), Berytos (Heb. *beroth*, 'wells'), Carthage or Carthado (Heb. *kereth kadashah*, 'new town'), Byrsa (Heb. *botsrah*, 'citadel,' cf. *Is. lxvii. 17*), Sufes (Heb. *shophet*, 'judge'), Asdrubal (Heb. 'Baal's help'), Hannibal and Hamilcar (Heb. 'favour of Baal' and of 'Milcar'), &c. Among Phœnician writers the first place is usually assigned to a certain Sanchuniathon (q. v.), a work by whom is said to have been translated into Greek by Philo of Byblos, a Phœnician of the time of the Emperor Adrian (117-138 A.D.), of which translation fragments have been preserved by Eusebius (*Præp. Evang.*); but the very existence of Sanchuniathon is now strenuously denied, and the work that goes under his name is held to be a forgery by Philo-himself. Three Phœnician historians are mentioned by Tatian (*adv. Gent.*)—Theodotus, Hysicrates, and Mochus; the last also by Athenæus, Strabo, Josephus (*Ant. i. 3, 9*). The Carthaginians could also boast of their literature. Mago, a general, about 600 B.C., wrote a work on agriculture, which, after the destruction of Carthage, was translated into Latin (*De Re Rustica*) and Greek. Hamilcar, perhaps the son of Mago, wrote on the same subject. Himilco, the son of Hamilcar, wrote an account of his voyages to the W. coast of Europe, as did his brother Hanno for his voyages to the W. of Africa. The famous Hannibal (q. v.) is said by Livy to have written an account of his deeds. Several of the Numidian kings also wrote works in the Punic language. Of the scanty remains of Phœnician civilisation, the principal are the inscriptions (1) on the sarcophagus of King Eshmunazar discovered near Zidon in 1854, (2) on a stone disinterred in 1845 near Marseille, and (3) on the monument at Dhiban in Moab, discovered in 1868. As to the invention of the alphabet by the Phœnicians, see SEMITIC LANGUAGES.

History.—The history of P. may be divided into four periods—(1) the first or pre-historic, ending about B.C. 1500; (2) the period of the supremacy of Zidon, from about B.C. 1500 to B.C. 1209; (3) that of the supremacy of Tyre, from B.C. 1209 to about B.C. 750; and (4) a period of decline, from about B.C. 750 to B.C. 65, when the country was merged in the Roman Empire. 1. Till about B.C. 1500 the attention of the early settlers in P. seems to have been occupied with the development of their immense internal resources, and laying the foundation of that commerce which afterwards filled the world. 2. About that time Zidon began to assume the rule, which marks the beginning of a new era. When the Hebrews arrived in Palestine, Zidon was

already the first-born of Canaan (*Gen. x. 15*), and the 'great Zidon' (*Joshua xi. 8*; *xix. 28*), in fact giving its name to the whole nation (*Joshua xiii. 6*; *Judges xviii. 7*). 3. Tyre, which had, however, existed for a time independently of her supposed mother-city Zidon, having been a 'strong city' in the time of Joshua (*xix. 29*), was greatly augmented in the year 1209 B.C., when the Zidonians, defeated by the Philistines, transferred themselves, commerce, manufactures, and all, to the more secure position of Tyre, which was situated on an island. At this point Zidon almost disappears from history for a time, being completely eclipsed and perhaps rendered tributary by her younger rival, which remained the capital of the whole country, although the name of Zidonians, seems to have been applied to the Phœnicians generally. Thus Hiram, King of Tyre (B.C. 980-947), who formed an alliance with Solomon (*1 Kings v. 1*; *ix. 27*), and with whom the real history of P. begins, is supposed to have command of the Zidonians (*1 Kings v. 6*), and Ethbaal (B.C. 898-866), the father-in-law of Baal, who in the Bible is called King of the Zidonians (*1 Kings xvi. 31*) was, according to Menander (*Jos. Ant. viii. 13, 2*), king of Tyre. Tyre in turn was weakened by the departure, owing to political dissensions and party quarrels, of the emigrants who established the city of Carthage (B.C. 813). That city, by drawing off a great deal of the wealth and trade of the parent city, injured it, just as Tyre itself had formerly injured Zidon. About the same time similar causes produced a similar emigration from Zidon, by which the town of Aradus was founded. This town afterwards entered into a confederation with Tyre and Zidon, which gave rise to the building, by settlements from the three, of the triple town of Tripolis, for the holding of their common council. 4. On the invasion of Palestine by Shalmaneser, king of Assyria (about B.C. 730), Zidon, Ake (Acre), Palætyrus (Old Tyre), and other cities of P. voluntarily submitted to him, and, when Tyre refused to do likewise, helped him against that city. But the Tyrians defeated with twelve vessels the fleet of sixty with which the other Phœnicians had provided Shalmaneser, who thereupon attempted to compel them to surrender by cutting off their water supply. The siege, however, after having been kept up for five years, seems to have been raised, probably on the death of Shalmaneser. This account by Menander (*Jos. Ant. ix. 14, 2*) is unconfirmed by any other authority, and some think the invasion must rather have taken place under Shalmaneser's successor, Sargon; but however that may be, Tyre, although not heard of again for about a century, still remained a powerful and wealthy state, with its own kings, and even employing mercenary troops (cf. *Jer. xxvii. 3*; *Ez. xxvi.-xxviii.*; *Zech. ix. 3*). On the invasion of Nebuchadnezzar (about B.C. 605), Zidon, which had meantime been again rising in importance, and perhaps got a king of its own (cf. *Jer. xxv. 22, xxvii. 3*), submitted at once, while Tyre, holding out as before, was subjected to a siege of thirteen years, although the result is again uncertain (*Jos. c. Apion, i. 21*). During the Persian domination, Zidon seems to have attained to its highest point of prosperity, and was for a time the wealthiest and most important city of P. In the expedition of Xerxes against Greece (B.C. 484), the Phœnicians supplied the best vessels of his fleet, and the Zidonians the best of them. But having revolted against the Persians under Artaxerxes Ochus (B.C. 359-338), and being betrayed by their king Tennes when their city was besieged, the Zidonians set fire to their own houses, and 40,000 are said to have perished (B.C. 351). After the battle of Issus (B.C. 333), Zidon, which had been speedily rebuilt and repeopled, as on two former occasions, opened her gates to the invader, while Tyre was besieged. Alexander, being greatly assisted by ships furnished by the other cities, Zidon, Aradus, and Byblos, it was this time undoubtedly taken, after a siege of seven months. Under the successors of Alexander the whole of P. came under the sway of the Seleucids (q. v.), and shared their fortunes, with the exception of Zidon, which again rose to such wealth and power, that Antiochus (III.), in his war with Ptolemy, was afraid to attack it (B.C. 218-216). P. was incorporated as a part of the Roman province of Syria by Pompey (B.C. 65). During the civil wars Tyre and Zidon seem to have again enjoyed a kind of independence (cf. *Jos. Ant. xv. 4, 1*), the former even having a king of its own; but of this they were finally deprived when Augustus visited the East (B.C. 20); although they continued to be towns of some importance till the end of the 13th c. See Robinson's *Bibl. Res.* (1841 and 1856); Kenrick's *P.* (Lond. 1855); Porter's

Handbook for Syria and Pal. (1858); Morer's *Die Phänizier und Das Phan. Alterthum* (Berl. 1841-56); Ewald's *Lehrbuch d. Hebr. Sprache. Erklär. d. gr. Phän. Inschr. v. Sidon* (Gött. 1856); and in *Abhandl. d. Königl. Gesellsch. d. Juden* (Leips. 1874); Renan's *Mission de Phénice* (1874), and Von Hans Prutz' *Aus Phönizien: Geographische Skizzen und Historischen Studien* (Leips. 1876).

Phœnicopterus. See FLAMINGO.

Phœnix, a fabulous bird, in shape and size resembling an eagle, with red and golden plumage, was said to burn itself upon a pyre, from whose ashes a new P. sprang. Another version ran that the old bird, at the approach of death, built itself a nest in Arabia, and that from this nest a young one was generated, who, casing its parent's body in an egg of myrrh, flew away with it to the temple of Heliopolis in Egypt. The P. was variously held to live for 500 or 1500 years, was said to have been four times seen in Egypt, and was regarded both by the ancient Egyptians and by early Christian writers (e.g., in the Epistle of Clement) as a symbol of immortality.

Phoenix. See DATE PALM and PALMS.

Pho'las, or **Pidd'ock**, a genus of *Lamellibranchiate* Mollusca, noted for a habit of stone-boring. By means of their shells they bore into rocks of all kinds, and lie ensconced in their burrows, communication being kept up with the outer world by means of the elongated *siphons* or breathing-tubes, which protrude from one extremity of the shell. The genus P. belongs to the family *Pholadidae*. In this group the shell gapes at either end, and has no hinge or ligament, being often provided with accessory valves or pieces. The P. has a short body and a small foot. The mantle is partly closed, and the siphons are long and are united throughout their length. *P. dactylus*, *P. papyracea*, *P. candida*, are three familiar species, and one species *P. costata* of the S. American coasts affords food to the natives. Allied to the P. is the *Teredo* (q. v.) or Shipworm, so famous for its destructive habit of boring into wood of all kinds.

Phonetic Writing has been defined as 'visible speech.' With our present orthography a foreigner can only learn the sound of *gaol* just as the first spectators of *Hamlet* or *Macbeth* knew whether the scene was laid in Denmark or in Scotland, viz., by being told. And this telling, and the remembering what is told, take no little time. A child will learn a thousand words phonetically spelled, like *fun*, *pig*, *mat*, in shorter time than twenty-five such traditional spellings as *buy*, *by*, *bye*, *tu*, and *high*. Well, then, if he belongs to the upper classes of society, where 'correct' orthography is a *sine qua non*, he may, after fifteen years of constant practice, attain a fair proficiency, or he may be one of the 90 per cent. who, Dr. Morell tells us, are plucked for spelling in the Civil Service examinations. If, on the other hand, he is one of the masses, whose education ceases with entrance on their 'teens, not only will he spell like Thackeray's 'Jeames,' but he will be unable to read our simplest writers; in the first two paragraphs of *Robinson Crusoe*, for example, being brought to a standstill by *colonel*, *foreigner*, and *lieutenant*. In 1873, 60 per cent. of the children leaving school had not reached the fourth standard, only 10 per cent. had passed in the sixth. The problem, therefore, of spelling reform, is to reduce all difficulties to a minimum, both in point of quality and quantity—to spell *buy*, for instance, *bi*, and *high*, *ti*, &c., on a similar principle. In America, where Franklin put forward a system more than a century back, phonetic spelling has found considerable favour, and an American book is easily recognised by the forms *honor*, *skeptic*, *traveler*, &c. In Germany, too, there is a growing tendency to drop such superfluous letters as the *h* in *theil*, or the second *n* in *mann*. But in England the question of spelling reform, though ably brought before the public for close on forty years, has been taken up by few educationists and fewer philologists, and even these are now divided between three separate schemes, each claiming to be better than the rest. These, to take the one that is least radical in its changes first, are the Glossic of Mr. Ellis, the Romic of Mr. Sweet, and, earliest of the three in point of date, the system invented by Mr. Isaac Pitman. Glossic, based on the present value of letters, takes as its vowel key-words: in *a*, *giat*, *baa*, *buil*,

caul; in *e*, *net*, *beet*, *height*, *feud*; in *i*, *knit*; in *o*, *not*, *cool*, *coal*, *foal*, *foul*; and in *u*, *nut*, *fuot* (for *foot*). Its only consonantal symbols calling for special notice are exemplified in *chest* and *jest*, in *skin* and *chen* (for *then*), and in *rush* and *rouche* (for *rouge*). Specimens of Glossic are *lain* for *lane*, *groo* for *grew*, *myth* for *myth*, *tis* for *phthisis*, *eil* for *isle*, *nau* for *gnaw*, and so on. Here we see an essentially conciliatory method, introducing no new characters, applying no new principle, and altering a comparatively small number of words, whilst at the same time it is calculated to reduce the time and labour spent in teaching reading and spelling by at least one third. Romic, which stands next, returns to the original Roman value of the letters, giving to *i* and *u* the sound they have respectively in *pique* and *pull*. That it is a far more complicated system than the foregoing may be gathered from the fact that to Mr. Sweet's *Handbook* a list is prefixed of 130 'of the more important symbols employed in the work.' Among these symbols 'turned' letters figure conspicuously, *air* being expressed by *æw*, and *up* by *ʒp*. Mr. Sweet professes to have avoided the use of new types, but there can be no question that, with existing founts, a compositor would set up Greek or Hebrew more easily than such a line as the following: 'and ewriwān dhāt hiirith dhiiz seingz ov main, and duuith dhēm not, shæl bi laikōnd ant'uu,' &c. This is as perplexing to the reader as was the 'Looking Glass' writing to Alice, and further suggests an uncomfortable impression of topsy-turviness. Eminent scientific Romic may be, and doubtless is, but it is strikingly deficient in those practical features without which no phonetic system can ever hope to come into general use. Lastly, in Mr. Pitman's method new symbols are freely introduced, *tch*, *dg*, *ng*, *oo*, &c., having each their respective character. The alphabet comprises forty letters, viz., eight mutes (*p*, *b*, *t*, *d*, *tch* of *etch*, *j*, *k*, *g*), eight continuants (*f*, *v*, *th* of *wreath*, *th* of *wreathe*, *s*, *z*, *c* of *rudus*, *s* of *vision*), three nasals (*m*, *n*, *ng*), two liquids (*l*, *r*), two coascent (*re*, *y*), one aspirate (*h*), twelve vowels (*a* of *am*, *a* of *alm*, *e* of *el*, *a* of *ale*, *i* of *ill*, *ee* of *et*, *o* of *on*, *a* of *all*, *u* of *up*, *u* of *fully* *oo* of *food*), and four diphthongs (*y* of *by*, *ew* of *new*, *ow* of *now*, *oy* of *boy*). With these forty letters Mr. Pitman endeavours, and successfully, to express the English language on broad and simple principles, avoiding those infinite shades of pronunciation which may be interesting enough to an investigator of acoustics or phonetics, but to an unscientific learner could only be as bewildering as a lecture on the structural anatomy of the leg to a toddling child. It is this very simplicity which has won for Mr. Pitman's method the cordial approbation of no less an authority than Professor Max Müller, and which has enabled poor Glasgow children to read the Sermon on the Mount after six hours' teaching. Phonetic spelling is not pledged, as Archbishop Trench assumes in his *English Past and Present*, to record every dialectic variety—in Somersetshire to spell *sow* with a *z*, and in London omit the aspirate in *head*. On the contrary, its first and indispensable duty is to provide a standard of pronunciation, which may show the only way in which a word should be pronounced, and consequently written. As a single example, with our present orthography a Cockney might defend his *'ome* and *'orse* by pointing to *hair* and *honour*, but phonetic spelling, by abolishing the mute, would at once dispel the doubt. Which, or whether any of the systems now proposed, will ultimately prevail, natural selection must show. Mr. Sweet's is, we believe, too artificial and pre-Raphaelite in its minuteness; against Mr. Pitman's the vested interests of a vast body of printers stand arrayed. But that a change will come, sooner or later, in the orthography of the English language is evinced by the awakening interest of school boards and other potentates, of literary journals, and of the country at large. See ORTHOGRAPHY: A. J. Ellis, *Plea for Phonetic Spelling, or the Necessity for Orthographic Reform* (Lond. 1844), *The Essentials of Phonetics* (Lond. 1848), *English Phonetics* (Lond. 1854), and *Universal Writing and Printing with Ordinary Letters* (Edinb. 1856); I. Pitman, *Phonography, or Writing of Sound* (Bath, 1840); B. Pitman, *Manual of Phonography* (New York, 1860); M. A. Bell, *Visible Speech* (1867); F. Jones, *Popular Education: A Revision of English Spelling a National Necessity* (Lond. 1875); H. Sweet, *Handbook of Phonetics* (Oxf. Clar. Press, 1877); Max Müller, *On Spelling* (Bath, 1878); and F. G. Fleay, *English Sounds and English Spelling* (Lond. 1878).

Pho'nograph (Gr. *phōnē*, a 'sound' of the voice, and *graphē*, a 'writing'), is an ingenious contrivance by which a per-

manent record of uttered sounds is so obtained that they can be reproduced any number of times afterwards. It is the invention of Mr. Eddison of New York, and its most wonderful characteristic is its extreme simplicity. It consists of a thin membrane stretched in front of the side of a cylinder coated with soft tinfoil. To the membrane a sharp point is fixed, which presses against the tinfoil. If a person speaks into the membrane, it and the attached style will be set into vibrations which coincide with the air-vibrations generated by the spoken sounds, and if at the same time the cylinder be rotated uniformly round its axis, the point of the style will impress a furrow upon the tinfoil. This furrow is an exact impress of the vibrations, and may be used to reverse the process—that is, by its action upon the point, the membrane may be set into vibrations exactly similar to the vibrations by which the furrow was originally formed, and those vibrations may be transferred to the air and heard as sounds. The instrument, like the telephone, is still in its infancy, and to what extent it may be developed can only as yet be matter of wildest conjecture.

Phonology. See PHONETIC WRITING.

Phonomania. See HOMICIDAL MANIA.

Phormium, or **New Zealand Flax**, as it was formerly misleadingly termed, is a plant belonging to the natural order *Liliaceæ*, and indigenous to New Zealand and Norfolk Island. Two species, *P. tenax* and *P. Colensoi*, are known, but the Maoris (q. v.) distinguish fifty-eight different varieties. The *P.* grows in bunches, each bunch producing about fifty leaves,

Phormium tenax.

which are perennial, hard, sword-shaped, from 5 to 7 feet long, and from 2 to 4 inches wide. The flower-stalk is 4 or 5 feet longer, and bears a profusion of red or brownish-yellow flowers. The seeds are flat, shining, and black, and are enclosed in a triangular capsule. The *P.* flourishes best by the side of running streams or in well-drained swamps. It does not grow at a higher elevation than 2000 feet, nor, in the South Island, far from the coast. Its inability to withstand frost prevents it from being reared in the open air in Britain, except in a few sheltered spots. The fibre is used by the Maoris in the manufacture of cordage, nets, and mats. Their mode of preparing it is by scraping the leaf with a mussel-shell, which produces an excellent article, but is very wasteful. By the use of machinery, sixteen times as much fibre can be obtained from an acre of *P.* plants. In 1870 the value of the *P.* fibre exported from New Zealand was £132,578, but is now (1878) probably only a tenth of that amount. The principal difficulty encountered is in the removal of a viscid juice which the leaves contain, but regular cultivation and cheaper labour are also required. Even under the present disadvantageous conditions, however, ropes of *P.* fibre are manufactured in the colony, while its adaptability for sacking, sheeting, towel-

ling, and even for fine tablecloths, has been proved at Arbroath, Kirkcaldy, and Leven. *P.* ropes will bear a very severe longitudinal strain, but break much more easily when knotted. They will not take tar, and must be oiled to resist the action of sea-water. *P.* cultivation on an extensive scale has recently been commenced at St. Helena, where the plant is reported to thrive.

Phosgene Gas, a compound of chlorine and carbonic acid, formed by the direct union of equal quantities of these gases in the sunlight. The action does not take place in the dark. It is a colourless gas, with a strong, suffocating odour; is decomposed by water into hydrochloric and carbonic acids; and has a specific gravity of 3.4249. Its composition is COCl_2 .

Phosphates. See PHOSPHORUS.

Phosphatic Diathesis, in medicine, designates the constitutional tendency to deposit *white gravel* in the urine. The deposit of phosphate of lime generally appears as a white cloudy mass resembling mucus or muco-pus; but which is distinguished from albumen by the precipitate which is produced by heat being re-dissolved by acids. On microscopic examination, it generally appears as an amorphous mass; but after standing it appears as spherules which may coalesce in a dumb-bell or rosette-like form, or in oblique hexagonal prisms. The triple phosphate of ammonia and magnesia appears in the form of large, conspicuous, triangular prisms, with truncated extremities, or of foliaceous or stellate prisms. Both kinds of phosphatic deposit may be mixed in the urine, which is often very fetid, and frequently acid or neutral, though generally alkaline. Alkalescence of the urine may be caused by the presence of the carbonate of soda or of potash, or of the alkaline phosphate of soda; or from the presence of the carbonate of ammonia, due to the decomposition of urea, from the action of the mucus of the bladder. The *white gravel*, under the latter condition, is composed of the triple phosphates, which are thus formed. Healthy urine contains phosphate of magnesia in solution; but when the urine becomes alkaline from the decomposition of the urea, a portion of the freed ammonia combines with the phosphate of magnesia and forms the triple salt, which is almost always mixed with a portion of the amorphous phosphate of lime. The *P. D.* is especially observed in chronic inflammation of the mucous coat of the bladder, and in disease or injury of the spinal cord. When phosphate of lime is present, the urine is alkaline, pale, slightly turbid, of a peculiar odour and of low specific gravity. It renders litmus paper *permanently* blue; while ammoniacal urine does so only *temporarily*. The *P. D.* is frequently characteristic of persons of a sallow, languid, unhealthy appearance, whose constitutions have suffered from general ill-health, mental anxiety, or sexual excesses. The treatment of such cases is chiefly dietetic, and tonics are of great value. Benzoic acid may be given with the view of restoring the acidity to the urine; and, in the ammoniacal form of the disease, the bladder should be washed out with tepid injections.

Phosphorescence (from Gr. *phosphorus*, 'light bearer'), a property possessed by almost all bodies, in virtue of which they remain visible for a longer or shorter time after they have been completely shut off from extraneous sources of light. The shining of phosphorus in the dark is the phenomenon from which the name is derived. This phenomenon is generally explained as due to the slow combustion of the phosphorus in the air, the energy of chemical combination being transformed into light. It is therefore not a true case of *P.* excited by the action of light was fully investigated by E. Becquerel. Aided by an ingenious instrument called the phosphoroscope, its presence could be detected though it lasted for only $\frac{1}{100000}$ th part of a second after the shutting off of the light. Action of heat renders certain bodies, such as the diamond, fluorspar, &c., phosphorescent; and many crystals, when simply broken, exhibit the same phenomenon. The rays which produce *P.* are of high refrangibility, becoming, as it were, degraded by absorption, and emitted as light rays. Fluorescence (q. v.) is a similar phenomenon; and the two have indeed many peculiarities in common.

Phosphorus (Gr. 'light bearer') ($P = 31$), a non-metallic element, discovered in 1669 by Brandt. When pure, it has a specific gravity of 1.82, and is a nearly colourless and transparent solid, but exposed to sunlight soon becomes opaque and reddish.

To preserve it pure it must be kept in water, free from air, since it gradually changes when exposed to the atmosphere even in the dark. It melts at 44°C ., and boils at 290°C . It spontaneously takes fire in air when heated a little above its melting point, burning with a brilliant white flame and evolving dense clouds of solid phosphoric acid. Even a stick of it will take fire under slight friction. It exists in several allotropic modifications. Besides the pure transparent kind and the white P. produced by sunlight, there is black P. It is formed by melting and sudden cooling, and is reconverted by refusion and slow cooling. If P. is heated to near its melting point and then suddenly cooled, it takes the viscous form. By subjecting ordinary P. for two or three days to a temperature of 230°C . under pressure in carbonic acid gas, it becomes an amorphous substance, red when pure, and of specific gravity 2.14. This modification differs markedly from the ordinary kind. It does not oxidise in the air at ordinary temperatures, has no odour, is not poisonous, and is insoluble in bisulphide of carbon and other phosphorus solvents. P. forms a large and most important series of compounds with other elements. It forms two oxides, known as phosphorous and phosphoric acids, and perhaps a third, the suboxide (P_2O), of which, however, little is known. Phosphorous acid (P_2O_3) is the product of the slow combustion of P., and decomposes when strongly heated into P. and phosphoric acid. Its hydrate ($\text{H}_3\text{P}_2\text{O}_5$) in solution is gradually converted into phosphoric acid by absorption of oxygen. Its salts are unimportant. Anhydrous phosphoric acid is produced when P. burns in air or oxygen. It is a white amorphous substance, extremely deliquescent. It is a powerful acid, and forms three distinct hydrates which differ in their chemical properties. They are the result of the combination of one molecule of the anhydrous with one, two, and three molecules of water, and are called respectively meta-, pyro-, and ortho-phosphoric acids. The first, also known as glacial phosphoric acid, is produced when the anhydrous acid is dissolved in water, and may be formed by oxidising P. with dilute nitric acid. Its formula is $\text{H}_2\text{O}, \text{P}_2\text{O}_5$, or HPO_3 . It acts on nitrate of silver to form the metaphosphate of silver ($\text{Ag}_3\text{O}, \text{P}_2\text{O}_5$). If the action take place in the presence of ammonia, the pyrophosphate of silver ($2\text{Ag}_2\text{O}, \text{P}_2\text{O}_5$) results. Similarly when a boiled solution of pyrophosphoric acid ($2\text{H}_2\text{O}, \text{P}_2\text{O}_5$) be tested with nitrate of silver and ammonia, the orthophosphate ($3\text{Ag}_2\text{O}, \text{P}_2\text{O}_5$) is obtained. Each hydrate then gives rise to a distinct series of salts. In the case of pyrophosphoric and ortho or common phosphoric acid, double salts may be formed, in which not all the molecules of water are replaced by another base, or in which the different molecules are replaced by equivalents of different bases. Thus common phosphate of soda is represented by the formula $2\text{Na}_2\text{O}, \text{H}_2\text{O}, \text{P}_2\text{O}_5$; microcosmic salt, a double phosphate of soda and ammonia, by the formula $\text{Na}_2\text{O}, (\text{NH}_4)_2\text{O}, \text{H}_2\text{O}, \text{P}_2\text{O}_5$; while a pyrophosphate of soda, having the composition $\text{Na}_2\text{O}, \text{H}_2\text{O}, \text{P}_2\text{O}_5$, has also been prepared. Two chlorides of P. are known, the trichloride (PCl_3) and the pentachloride (PCl_5). Both result from combustion of P. in chlorine gas, the former being obtained when P. is in excess, the latter when chlorine is in excess. The trichloride is somewhat unstable, and decomposes easily into P. and the pentachloride. With hydrogen P. forms three compounds—one solid (HP_2), one liquid (H_2P), and a gas, phosphureted hydrogen (H_3P). The liquid is volatile, and its vapour is spontaneously inflammable in the air. Phosphureted hydrogen is obtained by gently heating P. in a solution of caustic potash. It is insoluble in water, and highly inflammable in the air when prepared by this method. This inflammability, however, is due to the presence of the vapour of the liquid phosphide, since the pure gas, obtained by heating phosphorous acid, does not take fire spontaneously. The compounds of P. with nitrogen, sulphur, &c., are unimportant. P. is never found uncombined in nature; but its phosphates are common in mineral, vegetable, and animal matter. The principal earthy component of the bones is phosphate of calcium, which is obtained by the animal from the seeds of plants, where the processes of nature have stored it up. The bone ash which is left after the burning of bones is the great source of our P., and consists for the most part of phosphate of lime ($3\text{CaO}, \text{P}_2\text{O}_5$). This is reduced to a fine powder and treated with a solution of sulphuric acid, when the sulphate of lime and the acid phosphate of lime are obtained. To obtain P., the solution of acid phosphate is evaporated down to a syrupy consistency, intimately mixed with powdered char-

coal, and subjected to a white heat. The acid phosphate is decomposed, the calcium combines with P. and oxygen present to form the normal phosphate, the orthophosphoric acid breaks up in the presence of the carbon, and P., hydrogen, and carbonic oxide result. The most important of the industrial uses of pure P. is the manufacture of lucifer matches.

PHOTIUS, the great promoter of the schism between the Eastern and Western Churches, came of illustrious though unknown lineage, and had filled various high offices of state, when in the winter of 858 he was suddenly called to the patriarchate of Constantinople in place of Ignatius (q. v.), deposed by the profligate Bardas, uncle to the Emperor Michael VI. Hurried in five successive days through the preliminary orders of monk, reader, subdeacon, deacon, and priest, P. himself owned the irregularity of his investiture by the apologetic tone of his letter to Pope Nicholas I. But Ignatius, also appealing to the same supreme arbiter, prevailed, and in the teeth of packed and servile councils was reinstated in his see (862). Thereupon P. answered anathema by anathema, in a fresh council (867) deposed his deposer, and renounced communion with Rome. The murder of Bardas and Michael, and the accession of Basil the Macedonian (September 24, 867) were followed by the restoration of Ignatius and the banishment of P., a sentence confirmed in the eighth Ecumenical Council (869). But the fallen patriarch soon flattered himself into the new emperor's confidence, and scarcely was Ignatius dead (877) when he was once more seated on the patriarchal throne. Joannes VIII., more pliant than his predecessor Nicholas, granted him absolution, but disputed the jurisdiction of Bulgaria, and in 879 P. convened the fourth Council of Constantinople, which sealed the schism beyond recall by its nullification of the Council of 869 and by excising the *filioque* from the Creed. A charge of conspiring against Leo VI., Basil's son and successor, caused P.'s banishment to Armenia, where he died about the year 891. The protagonist in an eventful drama, P. has been held up by his partisans as a model of holiness and purity of morals, by his opponents as a forger, a hypocrite, a very monster of iniquity. Here, as so often, the truth lies probably somewhere between the two extremes, and much of P.'s laxity of conduct was the inevitable outcome of the venal and corrupt society on which his lot was cast. His learning, at least, was peculiarly his own, and its depth and variety are preserved to us in thirteen of his published writings, the principal of which are the *Myriobiblon seu Bibliotheca*, a summary of 280 Greek MSS., most of which have otherwise perished (edit. by Bekker, 2 vols. Berl. 1824-25); *Novum canon*, a collection of the canons of the councils recognised by the Greek Church (edit. by Voellus, Par. 1661); *Lexicon* (edit. by Porson, Lond. 1822); and 248 *Epistole* (edit. by Mountagu, Lond. 1651). Other treatises are given in vols. i. and ii. of Mai's *Scriptorum Veterum Nova Collectio* (Rome, 1825-27). See Jäger's *Histoire de P.* (Par. 1844), Neale's *History of the Holy Eastern Church* (4 vols. 1847-51), and Lämmer's *Papst Nikolaus I. und die Byzantinische Staatskirche seiner Zeit* (Berl. 1857).

Photographic Engraving, is a term embracing the numerous processes which have been devised for producing an engraved plate from which impressions of a design obtained by the agency of light may be printed with ink. Niepce in 1827 first accomplished this by coating a metal plate with bitumen, which becomes insoluble when exposed to light. After exposing the plate in the camera, he dissolved with the usual menstrua the portions of the bitumen unaltered by light, and then etched with acid the revealed portions of the metal. This method is still practised in the production of zinc relief blocks suitable for letterpress printing. In 1845, Fizeau employed an acid menstruum to bite the dark parts of a Daguerreotype plate, whereby he obtained an image in relief. A more successful process, termed *photoglyphic engraving*, was invented by Fox Talbot in 1853. It depends on the imperviousness of bichromated gelatine, acted on by light, to an etching fluid. A metal plate is coated with that substance, and on being removed from exposure to light under a negative, a solution of bichloride of platinum or perchloride of iron is poured on, which penetrates the gelatine film with a rapidity directly proportional to the degree of protection afforded to the parts while exposed, and corrodes the supporting plate to varying depths. In 1854, Paul Pretsch, utilising the property possessed by bichromated gelatine, unaltered by light, of absorbing water and swelling,

obtained by electro-deposition an intaglio or a relief-printing surface. By means of a negative he procured a gelatine relief image, and, moulding this in gutta-percha, he prepared by electrolysis an intaglio plate. A transparent positive yielded a relief plate. P. called his process *photogalvanography*. The swelled gelatine process and the dissolved gelatine process (see PHOTOGRAPHY) are now utilised for the production of relief stereotype plates in place of woodcuts for book illustrations, but in most cases the plates are touched up with the tool before printing. See PHOTOLITHOGRAPHY.

Photography (Gr. *phōs*, 'light,' and *graphē*, 'a writing'). The art of producing pictures on chemically prepared surfaces by the agency of light. P. is founded on the chemical or molecular changes which the actinic or chemical rays of light effect on certain compounds, especially salts of silver, and salts of chromium in presence of organic matter. The chloride, bromide, and iodide of silver give off chlorine, bromine, and iodine respectively, being thus reduced to dark coloured sub-compounds of the metal. The iodide only changes, under the influence of light, when an absorbent for the free iodine is present, and the sensitiveness of the other two is materially increased in presence of such a body. Silver chloride or horn silver (*luna cornua* of the alchemists) was long ago known to blacken on exposure to sunlight. In 1777 Scheele the Swedish chemist ascertained that the blue and violet rays of the solar spectrum were most active in promoting this discolouration, and in 1801 Ritter demonstrated the existence of chemically active rays beyond the violet end of the spectrum. In 1802 Wedgwood and Sir Humphrey Davy published a process for obtaining profile delineations, and for copying paintings on glass, by the agency of light on nitrate of silver supported on white leather or paper. Wet chloride of silver was found to be more sensitive, but in no case could the fleeting image be rendered permanent. P. made no further advance till Nicéphore de Niépce of Châlons-sur-Saône succeeded in 1827 in producing a permanent sun-picture by a process which he called *Heliography*. He discovered that asphaltum, or bitumen of Judæa, acted on by light resisted the action of the usual solvents for that substance. Following up this important discovery he coated a silver plate with bitumen, and, after exposing it for some hours to the influence of light, controlled by the lens of a camera-obscura, he washed away the portions of bitumen unchanged by light, by means of naphtha and other fluids, and thus obtained a picture, the lights of which were represented by the bitumen, and shadows by the exposed portions of the plate. Niépce aimed at the production of a photo-engraved plate which could be printed from, and by etching the portions unprotected by bitumen he accomplished this in a rude way. This process is still utilised in the production of relief-blocks for letterpress printing (see PHOTOGRAPHIC ENGRAVING). Subsequently Niépce became acquainted with Daguerre, a French painter, who had likewise been endeavouring to obtain a permanent photographic image, and the two agreed to work in concert. After years of patient labour, Daguerre, whilst working with a silver plate coated with iodine, found that the vapour of mercury condensed on the parts of the plate affected by light and developed the image which had hitherto remained invisible. Niépce died before the important discovery could be communicated to him, and thereafter a copartnership was formed between Daguerre and Niépce's son, Isidore. A fixing agent had still to be sought for, and this in time being secured, a practicable photographic process became a reality (see DAGUERRETYPE). On failing to start a company to work the new invention, Daguerre offered it to the French Government, and he and Niépce the younger were rewarded with annuities. Daguerre's process was published in 1839. Concurrently with Daguerre's researches the late Mr. Fox Talbot was experimenting with silver chloride, and so early as 1834 he copied the forms of ferns, lace, &c., by the agency of light. He termed these permanent pictures *photogenic drawings*. The method by which they were obtained is the foundation of the present positive-printing process. In 1839 Talbot published his Calotype (q. v.) paper process, and two years later he patented his improvements on it. The calotype picture was a negative, that is, the lights and shades were reversed, and by waxing it to give transparency he obtained a positive picture, having the lights and shades as in nature, on sensitive paper placed in contact with the negative and exposed to sunlight. The calotype process was obviously a great

advance on the Daguerreotype, for whilst the latter required an exposure in the camera for each image, the former afforded an easy means of multiplying prints from the negative. On the publication of the foregoing processes many earnest workers furthered the new art by introducing new photographic agents and improving the camera. The use of hyposulphite of sodium, which is still employed as a fixing agent, was suggested by Sir John Herschell. Le Gray modified the calotype process by waxing the paper before the application of the sensitive film, and this modification proved of great value in landscape P., since the paper remained longer sensitive. In 1847 Niépce de St. Victor introduced his *albumen* process. He coated glass (the use of which as a support had been previously suggested by Herschell) with sensitised albumen, and thereby obtained a smoother surface than paper. That process gave excellent results, and continued to be practised till 1851, when Archer published his *collodion* process. Le Gray is known to have tried collodion as a support for the sensitive film, but Archer was the first to bring it into practical use. The collodion process yielded brilliant results, and it is now almost universally adopted. The following is an outline of it as practised:—A thin film of collodion containing an iodide and bromide is poured over a clean glass plate. When the film has 'set' the plate is plunged into nitrate of silver, whereby the film is impregnated with iodide and bromide of silver. The wet sensitive plate placed in a 'dark slide' is conveyed to the camera, where the light of an object is allowed to fall on it for a few seconds. The image, as yet invisible, is developed in the 'dark room' by pouring on ferrous-sulphate solution. The dark room is a chamber from which the actinic rays of light are excluded by the use of yellow or red glass. The image gradually appears with the application of the developing solution, and after washing in water it may be intensified with a solution containing pyrogallie acid, citric acid, and nitrate of silver. The plate is again washed and the image is fixed by removing the unaltered salts of silver with a solution of hyposulphite of sodium or cyanide of potassium. On removing with water all traces of the fixing agent, the plate is dried and varnished. The image is a negative one, and from it positive prints are procured on prepared albuminised paper containing chloride of sodium or ammonium. The paper is sensitised in nitrate of silver and afterwards exposed to sunlight in contact with the negative in a *printing-frame*. The light passes through the lights and half tones of the negative in varying intensity, and produces a proportionate blackening of the chloride of silver on the albuminised paper. On removing the print from the frame it is strengthened by means of a *toning* solution of chloride of gold and acetate of sodium. After washing in water the print is fixed with the hyposulphite of sodium solution, and thorough rinsing in water being repeated, the print is dried, mounted, and glazed under rollers. No developing agent is needed in positive printing on account of the extra sensitiveness of chloride of silver in presence of an excess of nitrate of silver to the action of the actinic rays.

The collodion negative process requires that the sensitised plate be exposed *wet*, for when dry it loses sensibility. This drawback renders the process impracticable for field-work, owing to the impedimenta requisite for its practice. By the invention of *dry plates*, however, the disadvantage has been surmounted, and the practice of landscape and astronomical P. greatly extended. In dry plates the collodion is preserved in a sensitive state for an indefinite time by coating it or mixing with it an 'organiser,' or organic substance, such as albumen, tannin, gelatine, gum, coffee, &c. After receiving the impact of light in the camera, these plates have simply to be protected from light for development at leisure. The preparation of sensitive plates for field use has lately been greatly simplified by the production of emulsions containing all the elements of a sensitive film. These compounds are prepared by emulsifying bromide of silver with collodion or gelatine, and adding glycerine; on being washed and dried, cut into shreds, and packed in the dark, they may be carried to any part of the world ready to be converted—the *collodio-bromide* by a mixture of ether and alcohol, and the *gelatino-bromide* by the action of warm water—into emulsions for immediate use. An alkaline re-agent instead of an acid one is employed in the development of dry plates.

Carbon Printing.—The want of permanency in silver prints, through careless manipulation, chiefly in washing away the

fixing agent, has created a fear that all silver prints may succumb to the action of time. Out of this fear of instability have arisen numerous processes for printing in permanent pigments. These processes are based on a peculiar property acquired by gelatine, or any similar colloid body, when sensitised with a chromium salt and acted on by light. The salt is split up, and the gelatine absorbing oxygen becomes insoluble in water. The germ of this change was discovered by Mungo Ponton in 1839. If paper be coated with gelatine containing a bichromate and a pigment, and be exposed to the varying intensities of light passing through a negative, the gelatine becomes insoluble to proportional depths. The soluble gelatine may then be washed away with hot water, with the result of developing a beautiful positive print in permanent colour. Such is the principle of carbon printing, or more correctly, pigment printing. This printing process, first rendered practicable by Mr. J. W. Swan of Newcastle, has of late years advanced to a great state of perfection, as demonstrated by the prints issued by the Autotype Company in London. They employ a 'tissue,' or paper thinly coated with gelatine charged with lampblack or other pigment and bichromate of potash or ammonia, and on removal from the printing-frame the tissue face is brought by pressure into close contact with gelatinised paper treated previously with chrome alum. The whole is then placed in warm water, in which the original paper support floats off, and the soluble gelatine is dissolved. If a 'double transfer' be necessary to bring the print into proper position, a temporary support of zinc or glass is employed during the washing operation, and the picture is thereafter transferred to paper.

Photo-Mechanical Printing Processes.—The gelatine image is further used to produce a matrix from which prints are mechanically obtained without the action of light. In the Woodbury-type process (named after the inventor) a relief picture in gelatine, hardened with chrome alum or other substance, is procured by the method adopted in carbon printing, and an impression of it is taken on a soft metal plate, as in *Nature Printing* (q. v.). Liquid coloured gelatine is poured over the plate, paper is laid on, and a perfectly flat and true metal plate is brought down over it. The gelatine is pressed into the depressions of the matrix, and the excess makes its exit at the edges. When the gelatine 'sets,' the paper is removed with the image adhering to it, and dipping into an alum solution renders the print insoluble. These gelatine pictures are mounted and used for illustrating books. By introducing a gritty powder into the bichromated gelatine before the formation of the image, a *grained* matrix is secured, from which impressions may be taken as in copperplate printing. The heliotype process of Mr. Ernest Edwards may be taken as a type of another class of photo-mechanical printing processes, embracing the Albertype, pantotype, &c., in which the hardened film of bichromated gelatine is itself printed from in an ordinary type or lithographic press. Bichromated gelatine on exposure to light, not only becomes insoluble, but it repels water and absorbs grease. Taking then a film and exposing it behind a negative, the property is acquired of refusing to absorb water in the exact ratio in which light has acted, while it takes a depth of fatty ink directly proportional to its repellent action on water. In the practice of the typical process, the gelatine film, supported on plate-glass, is, on removal from behind a 'reversed' negative, placed in cold water to remove the excess of bichromate and to develop the image in very slight relief. The impressions in lithographic ink pulled from the gelatine image exhibit all the gradations of tone of an ordinary photograph, and are particularly adapted for book illustration.

Photomicrography, by which enlarged permanent images of microscopic objects are depicted, through the adaptation of the microscope to the camera, and *astronomical P.*, are among the most recent triumphs of P. in promoting scientific research. For a description of these and other applications of P. to science and art (see PHOTOGRAPHIC ENGRAVING and PHOTOLITHOGRAPHY), as well as for full details of the operations and processes practised, Thomson's *Handbook and History of P.* (translated from the French of G. Tissandier, Lond. 1876), and Abney's *Treatise on P.* (Lond. 1877) should be consulted.

Photolithography is a method of producing photographic designs on stone which may be printed from in the ordinary way. P. is dependent on the reducing action of light on gelatine, and similar organic bodies, mixed with a bichromate. The parts acted on by light become insoluble in water, repel moisture,

and absorb grease. Poitevin, in 1855, patented a process for coating lithographic stone with bichromated gelatine and albumen, washing away the parts protected from light by the shades of a photographic negative, and pulling proofs directly from the developed image. P. is now accomplished by the *transfer* process. The gelatine film, subsequent to exposure beneath a negative, is coated with greasy ink, and the soluble parts of the film being washed away, the print is transferred by pressure to a lithographic stone, and impressions are obtained in the usual way. P., while eminently adapted for multiplying copies of maps, plans, &c., is not suited for reproducing pictures with fine gradations of light and shade.

Photoincography differs from P. in the substitution of a zinc plate for stone. It is extensively practised in the Ordnance Survey Office, Southampton, in reproducing plans, historical manuscripts, &c.

Photometer (Gr. *phōs*, 'light,' and *metron*, 'a measure'), an instrument for conducting photometry, or the measurement of light, by comparing one light with another and expressing their relative intensities numerically in virtue of the law of inverse squares. Several photometers have been invented. Bunsen's P. is generally adopted to ascertain the illuminating power of coal gas or other artificial light, the standard of comparison in Great Britain being a sperm candle of six to the pound weight burning 120 grains per hour. A grease spot on paper appears bright by transmitted light, and dark by reflected light; but if the paper be placed midway between two lights of equal intensity, the grease spot appears equally illuminated with the surrounding paper. This is the principle of Bunsen's P. The lights to be compared are placed on opposite sides of an oiled screen, and the brighter illuminant is removed farther from it, till equally illuminated surfaces be obtained: the distances of the lights from the screen are then measured and squared, and the two squares express the relative intensities of the lights. In Rumford's P. comparison is made of two shadows of an upright opaque rod cast upon a white screen from two sources of light. The darker shadow is produced by the more intense light, but by gradually withdrawing it the shadows at length become of equal force. The relative illuminating values are then determined as before. In the P. of Bouguer and in that invented by Ritchie, light from two sources is separately received by two inclined mirrors, placed in a box, and is reflected upwards to adjoining discs of oiled paper, equality of brightness being obtained by shifting one of the lights. Arago founded a P. on the properties of polarised light, but it, together with the instruments designed by Wheatstone, Leslie, and others, is of little value for practical purposes. The use of the radiometer for photometry has recently been suggested by Mr. Crookes.

Photophobia (Gr. *phōs*, 'light,' and *phobos*, 'fear') is an intolerance or dread of light characteristic of some forms of ophthalmia, more especially those of a strumous nature. In cases of recurrent vascular ulcer, the P. is excessive, and the child hides its head in the darkest corners or in its mother's dress, screams and struggles at every attempt to expose it to the light, and contracts the orbicular muscles spasmodically. The subjects of this disorder are nearly always strumous children, and the state of their eyes often renders them additionally unhealthy.

Photosculpture, invented in 1861 by M. Willème, an eminent French sculptor, is an art in which photography is turned to account in reproducing facsimiles of statues or living persons. The model is placed in the centre of a circular studio, and twenty-four simultaneous photographs are taken of it from different points of view. The block of clay to be modelled being now placed on a turn-plate, the outline of No. 1 photograph is scratched on it by means of the pantograph, an instrument for counter-drawing. On turning the block round $\frac{1}{24}$ th of a revolution, the contour of No. 2 photograph is similarly transferred to the clay, which is then cut according to the difference of the two profiles. Obviously, by so operating with the remaining photographs in their proper order, the clay block will, in a complete revolution, present the exact exterior outlines of the model, and the *minutiae* of the pictures being thereafter traced with the points of the pantograph, a solid figure, perfect in all the details of the photographs, is obtained. P., though an accurate and simple art, has not been extensively practised out of the country of its origin. The late M. A. Claudet of London was its most able exponent in Great Britain.

Photozincography. See **PHOTOLITHOGRAPHY.**

Phragmites. See **REED.**

Phrase, in music, a short portion of a section, containing one or more feet of one accented and one or two unaccented beats. *Phrasing* in compositions is the due indication of rhythmical divisions for performance, by giving proper stress to accented notes, &c., in order to ensure correct musical expression.

Phrenitis. See **MENINGITIS.**

Phrenology, a system of classification and localisation of the powers of mind, first propounded by Dr. Franz Joseph Gall, and subsequently by Dr. Spurzheim, Dr. A. Combe, Dr. G. Combe, and others. Gall is said, when a schoolboy, to have remarked that certain qualities of mind were associated in his fellow-pupils with special developments of certain parts of the brain, and he was hence led to correlate the two observations by assuming that it was possible to determine the mental constitution of man by observing the size and shape of the skull and its regions. His opinion is necessarily based on the idea that the brain is an aggregation of parts or organs, and that each organ has a distinct and separate function in the evolution of mind or mental acts. This idea forms one of the fundamental propositions of P., and may be accompanied by another, namely, that *ceteris paribus*, the size of the 'organs' or parts of the brain is indicative of this activity and power. Having thus mapped out the basis of the study, the phrenologist proceeds to assert that by observation of the conformation of the external surface of the brain the character may be accurately determined, and that by studying the elevations and depressions, alleged to be capable of being felt in the skull through the scalp, the exact form of the brain mass may be ascertained. The surface of the skull and head generally is thus mapped out by phrenologists with some thirty-five 'organs,' each being supposed to correspond with a definite mental power. The recognition of these organs by the phrenologist has necessitated the construction of a special system of classification of the mental powers. The arrangement of Combe divides the intellectual powers into *Affective* and *Intellectual* faculties. The affective faculties are further divided into *Propensities* and *Sentiments*, and the intellectual into *Perceptive* and *Reflective* faculties. The following is the list of faculties according to Combe:—

AFFECTIVE

I. PROPENSITIES.

1. Amativeness.
2. Philoprogenitiveness.
3. Concentrativeness.
4. Adhesiveness.
5. Combaticiveness.
6. Destructiveness.
7. Secretiveness.
8. Acquisitiveness.
9. Constructiveness.

II. SENTIMENTS.

10. Self-esteem.
11. Love of approbation.
12. Cautiousness.
13. Benevolence.
14. Veneration.
15. Firmness.
16. Conscientiousness.
17. Hope.
18. Wonder.
19. Ideality.
20. Wit.
21. Imitation.

INTELLECTUAL.

I. PERCEPTIVE.

22. Individuality.
23. Form.
24. Size.
25. Weight.
26. Colour.
27. Locality.
28. Number.
29. Order.
30. Eventuality.
31. Time.
32. Tune.
33. Language.

II. REFLECTIVE.

34. Comparison.
35. Causality.

Admitting with the phrenologists themselves that this system of classification is by no means perfect, there are yet sufficient materials offered therein for criticism of the system at large. One of the chief objections to P. has always been that the brain substance shows no trace or appearance of being divided into 'organs' or parts such as the phrenologist theoretically recognises. Nor does the development of the brain afford any support to the phrenologist. The development of an organ is regarded in modern physiology as the surest clue to its nature and structure. The brain arises from three 'vesicles,' which make their appearance at an early stage of development, and in its early growth exhibits no convolutions such as are seen in the brain of

the adult. There is thus not the slightest trace in the brain substance of any separation into the 'organs' of the phrenologist. Neither does comparative anatomy support P. Many animals (e.g., frogs) which exhibit the highest development of sexual activity have the cerebellum or lesser brain (where *amativeness* is placed by the phrenologist) represented by a mere strip of brain matter. Moreover, the knowledge we now possess of the functions of the cerebellum entirely refutes the phrenological idea of its being the seat of the sexual passion. This portion of the brain regulates the movements of the body and co-ordinates muscular motion. When removed from an animal, the creature has no power of moving harmoniously, but flies or walks in the most unsteady fashion. So also P. receives no support from pathology; for the cerebellum is not found diseased in those insane who are subject to strong sexual desires and to utter perversion of the sexual functions. What has just been said of the cerebellum, and of the phrenological doctrine of its uses, applies to every other 'organ' and to the system as a whole. The fact must not be lost sight of that if the convolutions of the brain are to be regarded as of equal value—and there is no justification for assuming the reverse notion—then those convolutions which are situated on the base of the skull must also be considered to possess definite functions. But P. has no means of reaching the base or floor of the skull, and the faculties of mind must therefore be regarded as being situated solely on the upper surface and outer parts of the brain—a supposition which in itself would effectually show the weakness and inapplicability of P. as a system of mind. Perhaps, however, the arguments which militate most powerfully against P. as a system of mind-localisation are derived from recent researches into the functions of the brain. With these researches the names of Hitzig and Ferrier are associated. By exposing and by electrically stimulating the brain, it has been ascertained that there is localisation of function in the brain it is true, but not of the mental or intellectual functions as postulated by P. It has been found that certain portions of the brain are associated with muscular movements of certain parts; and as far as research has yet proceeded, it would seem that groups of muscles derive their nerve power from, or are stimulated by, certain localised parts of the brain. Language, and the power of expressing ideas, has been located by P. in the eye, which organ is itself removed from the brain, and in its development corresponds largely to an infolded skin surface. Professor Ferrier's researches have shown that the condition of *aphasia* or *speechlessness* is produced by disease of the left hemisphere of the brain at the hinder part of its lower and frontal convolution. More curious still is it to find that aphasia is associated invariably with disease of the left hemisphere of the brain; the right side being invariably unaffected. Other regions of the brain have been shown to be the seat of sight, smell, taste, and touch. Thus the localisation of ordinary bodily functions in the brain has already been demonstrated, but the localisation of mind-functions is yet an unattempted physiological labour. One fact remains clear, however, and that is, that P. is utterly insufficient, when judged by the standard of physiology, to localise the functions of mind. It is founded on no certain experimental or scientific basis. See Prof. Laycock's *Mind and Brain*, &c. (Edinb. 1860), Sir Benjamin C. Brodie's *Psychological Inquiries* (Lond. 1854), Bailey's *Letters on the Philosophy of the Human Mind* (Lond. 1858), Sir William Hamilton's *Lectures on Metaphysics* (Edinb. 1859), Combe's *Relation between Religion and Science* (Edinb. 1857), and Prof. Bain, *On the Study of Character*, including an *Estimate of Phrenology* (Lond. 1861).

Phrygæna. See **CADDICE.**

Phrygia, called **P. Major** to distinguish it from **P. Minor** in Mysia, was a province in Asia Minor bounded E. by Galatia and Lycæonia, S. by Pisidia, W. by Caria, Lydia, and Mysia, and N. by Bithynia and Paphlagonia. It was traversed by irregular offsets from the mountain ranges of Olympus, Taurus, and Cadmus, and watered by the upper courses of the Hermus, the Meander with its tributaries the Marsyas and Lycus, and the Sangarius with its tributaries the Thymbres and Alander. In the S. were the salt lakes of Anaua (*Chardak*) and Ascania (*Buddur*). P. was divided into four parts—Salutaris, the central; Pacatiana, on the Carian frontier; Epictetus in the N., and Parorios, the mountainous district, in the S.; and was crossed by several important roads, those between Ephesus and the East meeting at Synnada, from which roads led to Cilicia, to Cæsarea in Cappadocia, and

thence into Armenia. The chief towns were Dorylæum (*Eske-Shehr*), Lynnada, Ipsus, Celenæ, Apamea, Colossæ, Laodicea, Hierapolis. The inhabitants came probably from the Armenian highlands, and settled in the plateau of Asia Minor. They are believed to have spread over Thrace, Macedonia, and Illyria, to have been an Aryan people, and kinsmen of the Hellenes. Though a brave race, they were forced to yield successively to the Semitic Assyrians, the Lydians, and the Persians. P. was permanently attached to the Roman province of Asia (B.C. 43). In religion the Phrygians were noted for a certain barbaric fervour. They loved orgies, were addicted to a kind of sensual mysticism, and exercised an influence more powerful than wholesome on Hellenic and Roman worship.

Phryne, a famous Greek courtesan, was born at Thespiae in Boeotia in the latter half of the 4th c. B.C. Coming early to Athens, she there acquired such riches by her venal charms that she was able to offer to rebuild the ruined walls of Thebes, if only an inscription might be set thereon—'Alexander demolished Thebes, but P., the hetaira, built it up.' Amongst her lovers were Apelles, who painted her as 'Venus Anadyomene'; the sculptor Praxiteles, who took her for his model of the 'Cnidian Venus'; and the orator Hyperides, who gained her acquittal from a charge of atheism by bidding her unveil her bosom before the judges.

Phthiria'sis. See LOUSINESS.

Phthisis (Gr. *phthiō*, 'I consume'), or **Pulmonary Consumption**, is an extremely common and a very fatal disease. It may attack either sex, at any age, and is more or less common to every race of mankind and to every clime. P. may be hereditary or acquired, acute or chronic. *Acute P.* is a comparatively rare disease, and runs a rapid course. The onset is sudden, the prominent symptoms being shivering followed by high fever, profuse perspiration, rapidly increasing weakness, pain, cough, dyspnoea, and hurried breathing. *Acute P.* seems dependent on tubercular degeneration, following catarrhal pneumonia, the consolidation breaking down into soft cheesy matter, cavities of various sizes being sometimes formed all over the chest. Small and large crepitations may be everywhere detected. *Chronic P.* is a much more common form of the disease. The more prominent general symptoms are loss of appetite, impaired digestion, an aversion to fatty foods, general debility, loss of weight, night sweats, and a dry cough, most severe at night or early in the morning. The cough is soon afterwards accompanied with a clear, sticky expectoration, frequently tinged with streaks or dots of blood, and when the expectoration of blood is abundant, vomiting accompanies the cough, and hence the term 'vomiting of blood.' In hæmorrhage from the stomach, the blood comes away by a single act of vomiting, followed by black discharges from the bowels; but in hæmorrhage from the lungs, succeeding coughs generally bring up remaining portions of blood, the colour becoming darker and darker, and finally of a dirty brownish-red. There is not generally any fixed pain; but often a dull, aching feeling between the shoulders or below the clavicles. Sometimes the fingers are club-shaped, the nails curved, and a red line may be seen on the gums. The tubercular deposit, as a rule, affects the apex of one lung at first, and want of elasticity or actual dulness may be detected in the supra-spinous or supra-clavicular region. Stethoscopic examination elicits prolonged expiration; and a feebleness, jerking, or dry clicking accompanies the respiratory sound. Increased exudation is evinced by sub-crepitant, bubbling sounds, or by bronchial or tubular breathing. When the general and local symptoms are obscure, the nature of the case may be decided by the thermometer, which will indicate an increase of the evening temperature over that of the morning to a greater or less extent. In the second and third stages of chronic P. the general symptoms are increased in intensity. The fever is intensified and hectic; there are profuse night sweats and diarrhoea; frequent and irritable cough, often accompanied with vomiting; capricious appetite, and impaired digestion; the expectoration is thick, yellow, heavy, and pellet-shaped or mummular, sometimes purulent and of an offensive odour, and there is flattening above and below the clavicles of one or both sides. The tubercles formed in the first stage break down, and cavities are formed, and the walls of the cavities are usually thick and solid. The percussion sound is dull, but if there be free communication

with the open bronchi and the mouth, there is the cracked-pot sound (*bruit de pot fêlé*). On auscultation gurgling may be heard, caused by the air bubbling through liquid, or cavernous or amphoric respiration if the cavity be dry, or both may be combined if the cavity contains fluid at its lower part and be dry above. Broncophony or well-marked pectoriloquy may be observed by the vocal resonance. A murmur is frequently heard below the clavicles, especially on the left side, following the first sound of the heart, probably due to adhesions at the apex of the lung. The nature of the disease can be determined by an examination of the sputa, for tubercular matter can be detected, and at times the elastic fibres of the lung-tissue.

Treatment.—From the first appearance of suspicious symptoms, cod-liver oil should be given, at first in tea-spoonful doses, mixed with lime-water, and gradually increased. Glycerine, either alone or with the syrup of the iodide of iron, or a bitter tonic, may be given, and pancreatic emulsion has been recommended. The curative treatment is essentially dietetic and hygienic, and in the early stage of the disease a change of air and scene is recommended. When circumstances admit, a sea-voyage should be tried, or a residence for some time in a genial climate such as Torquay, Mentone, Algiers, or Madeira. The palliative treatment consists in measures to allay the cough, such as the hop inhalation, which is preferable to cough mixtures. This is prepared by mixing half a drachm of oil of hops and one drachm of heavy carbonate of magnesia in three ounces of water. A tea-spoonful of the mixture added to a pint of boiling water may be used by the Maw's inhaler. Opium, or some of its preparations, may be used as a cough mixture. In cases of hæmoptysis, gallic acid or ice may be given internally, and the injection of ergotine is recommended. Chlorodyne is useful to control diarrhoea, and the hypophosphite of lime, or the injection of atropine, to control excessive perspiration. The hypophosphite of lime is recommended in the early stages of hereditary P. See TUBERCULOSIS.

Phulwara Tree is a name given in India to the butter-tree, for which see *BASSIA BUTYRACEA*.

Phylactery (Gr. 'a safeguard,' 'amulet,' the name in the New Testament for the Old Testament *frontlet*, Heb. *totapheth*, 'a tie, a band,' from *toph*, 'to bind round') is a small square box made of parchment or black calf-skin, in which are enclosed four slips of parchment or vellum, with a passage of Scripture written on each (Exod. xiii. 1-10, 11-16; Deut. vi. 4-9, xi. 13-21), which is worn by every Jew on week-day mornings during the time of prayer, one on the hand and another on the head. Each is fastened on by a long thong, and the chief difference between the two is that inside the one for the head are four cells, one for each of the four slips of parchment, while the one for the hand has only one cell. See *Kitto's Cyclopædia of Biblical Literature* (3d ed. Edinb. 1876).

Phyllopoda, an order of *Crustacea* (q. v.), which have usually though not always a *carapace* or shell investing the head and thorax. The feet never number less than eight pairs; while, as indicated by the name P. ('leaf-footed'), they are foliaceous or leaf-like in form, and bear the respiratory or breathing organs. The first pair of feet are used for swimming, and have no gills. In their development the P. undergo a somewhat modified metamorphosis, and the young appear as *Nauplii*. In this order several well-known crustacean forms are included. Of these, the genera *Apus*, *Limnadia*, and *Branchipus* are familiar groups, and the *Chirocephalus*, or genus of 'Fairy-shrimps,' also belong to this order. The well-known 'Brine-shrimps' (*Artemia*), found in the pans of saltworks, and in the Great Salt Lake of Utah, are also P. They live in a briny solution of sufficient strength to pickle beef.

Phylloxera, a genus of insects peculiarly destructive to vines. The French vineyards have suffered terribly from their attacks, and all the resources of entomologists and chemists have been called in to repress their ravages. Originally brought from America, they were apparently first noticed by Fitch, an American naturalist, in 1854, in the form of galls situated on the lower surface of the vine leaves. Each gall contained a small insect, invariably a female, and capable of producing some hundreds of eggs. From each egg a little larva issued; these larvae ascended to the upper part of the vines, and destroying the plant tissues, ultimately formed 'galls,' in which they became enclosed like

their parents. Dr. Shimer, in 1867, was fortunate enough to discern the male insect, which was winged. Meanwhile vine-pests were being met with in England. They appeared near London in 1863, but in 1867, in France, the vine-growers were forced to take measures for the repression of the new and mysterious lesion which affected their plants. The cause of this lesion long remained a mystery, until a careful examination of the diseased vines showed that they were infested with insects, which by their numbers caused the gangrene and decay of the plants. The conditions favouring the development of the P. are said to be cold and drought; but in reality our knowledge on this point is very slight and uncertain. Nor have the remedies hitherto proposed been thoroughly successful in the attempt to eradicate these pests. The most hopeful method appears to be that of fostering other insects which are harmless to the vines, but which prey on the P. Certain species of vines (e.g., *Vitis rotundifolia*) seem to escape its attack, and the cultivation of these has been recommended as likely to exterminate it.

Physalia, a genus of *Cœlenterate* animals, including the 'Portuguese men-of-war.' *P. pelagica* and *P. utriculus* are two well-known species. The P. is met with floating on the surface of tropical seas. The body consists of a beautifully tinted bladder or 'float,' which serves to buoy the organism on the surface of the water, and which attains a length of 8 or 9 inches. To the under surface of the float a large number of *zooids* or *polypites* are attached, the P. being thus a compound animal. Long contractile tentacles are also developed. These animals sting very severely by means of the *cnide* or 'thread-cells' with which, like all other *Cœlenterata*, they are provided. The effects of the sting may last for a long time, the symptoms resembling those of a very severe and acute inflammatory attack. Occasionally specimens of P. have been found on the coasts of Britain.

Physalis (Gr. *phusa*, 'a puffing up') is a genus of herbs and shrubs belonging to the natural order *Solanaceæ*, in which the calyx enlarges considerably after flowering, so that the succulent fruit is enclosed in a large leafy bladder. The species are widely distributed in tropical countries, and *P. Alkekengi*, or the winter cherry, is a native of middle and S. Europe. Its fruit, which is like a small cherry within the vernilion-coloured inflated calyx, has a slightly acid taste, and is eaten in some countries. It is also said to have some medicinal value. *P. Peruviana*, the Peruvian cherry, and *P. pubescens*, both natives of temperate and tropical America, yield a luscious fruit that is used for dessert

Physalis Alkekengi.

or made into preserves. The first is occasionally cultivated in forcing-houses in Britain, and is often very naively called Cape Gooseberry.

Physæter. See CACHALOT.

Phys'ical Geography. See GEOGRAPHY.

Physicians, The Royal College of (of London), was founded in 1518 by Thomas Linacre (q.v.). Through the influence of Cardinal Wolsey, Linacre obtained from Henry VIII. letters patent granting to John Chambre, Ferdinandus de Victoria, and himself, physicians to the king, along with Nicholas Halsewell, John Francis, Robert Yaxley, and all other men of the same faculty in London, to be incorporated as a perpetual community or college. Linacre was the first president, and held the office till his death. The parties named were empowered to hold assemblies, and form laws for the government of the College, and of all who practised medicine in London and within seven miles thereof, with the power to interdict from practice any individual, unless previously licensed by the president and College. The original charter was obtained 'to check men who

profess physic rather from avarice than from good faith, to the damage of credulous people.' The charter ordains that 'no one shall exercise the faculty of physic in the said city, or within seven miles, without the College licence, under a penalty of £5; that, in addition to the President, 'four censors be elected annually to have correction of physicians in London and seven miles' circuit, and of their medicines, and to punish by fine and imprisonment,' and that 'the President and College be exempt from serving on juries.' In 1523, an Act was passed confirming the charter, and enacting that the six persons named 'shall choose to them two men of the said commonality from henceforward to be called and cleaped elects, and that the same elects yearly choose one of them to be president of the said community.' It was further enacted that, in the event of a vacancy, the elects 'shall choose, name, and admit, one or two, as needs shall require, of the most cunning and expert men, of and in the said faculty in London,' and that 'no person from henceforth be suffered to exercise or practise in physic except he be a graduate of Oxford or Cambridge, until such time as he be examined at London by the said President and three of the said elects, and have from them letters or testimonials of their approving and examination.' Additional privileges and powers were conferred by an Act passed in 1540, by which the President and College were exempted, on account of their professional duties, from certain public duties which devolved on other citizens; and empowered to enter and search the houses and shops of apothecaries, and to destroy such articles as they might find 'not meet nor convenient to be ministered in any medicine for the health of man's body.' In this Act it was declared that 'surgery is a part of physic, and may be practised by any of the company or fellowship of physicians;' but, until very recent times, this recognition was denied by the College. Several Acts were subsequently passed, but nothing of any great importance occurred until the passing of the Medical Act of 1858, which provided for the granting of a new charter to the College, which was obtained in 1862. In 1860 'An Act to Amend the Medical Act' was passed, by which the provisions of the Act 1522-23, as to the elects, were repealed on the ground that their main function was licensing country physicians, and that it had virtually ceased. The Act further declares that the office and name of elects of the said College shall henceforth wholly cease, and that the presidency shall, in future, be an annual office, open to the fellows at large, who shall also be the electing body.

The meetings of the College were first held at the house of Linacre in Knightrider Street, which he bequeathed to the College, and which they possessed till 1860. During the reign of Charles I., more accommodation being required, a house was taken at the bottom of Amen Corner, which was the seat of the College till 1666, when it was destroyed by the great fire of London. A new building was afterwards erected in Warwick Lane, which was opened in 1674 under the presidency of Sir George Ent, and where the meetings were held until 1825, when the present building in Pall Mall East was opened under the presidency of Sir Henry Hallford.

The College consists of fellows, members, licentiates, and extra-licentiates, and the government of the College is vested in the president and fellows only, the members of the College being alone eligible to the fellowship. The College, under its charter, grants licences to practise physic, including therein the practice of medicine, surgery, and midwifery, to persons who conform to the byelaws of the College. Each candidate for the licence must produce evidence (1) of having attained the age of twenty-one years; (2) of moral character; (3) of having passed, before the commencement of professional study, an examination in the subjects of general education recognised by the College; (4) of having been registered as a medical student in the manner prescribed by the General Medical Council; (5) of having been engaged in professional studies during four years; (6) of having attended, during three winter sessions and two summer sessions, the medical and surgical practice at a recognised hospital or hospitals, &c.; (7) of having pursued a prescribed course of study; (8) of having passed the professional examination. Licentiates of the College prior to 1859 are entitled to be admitted as members. Extra-licentiates, not engaged in the practice of pharmacy, may be proposed as members. There are twenty-one byelaws and regulations regarding the admission of members. Candidates must have attained the age of twenty-five; must produce a testimonial as to character, &c., from a

member or fellow; and evidence of having been engaged in professional study during a period of five years. No candidate can be admitted who is engaged in trade, or who dispenses medicines, or who practises medicine or surgery in partnership; or who refuses to make known, when required by the President or censors, the nature and composition of any remedy he uses.

According to the byelaws of the College—(1) no fellow of the College is entitled to sue for professional aid rendered by him; but this byelaw does not extend to members; (2) no fellow, member, or licentiate of the College is entitled to assume the title of doctor of medicine unless he be a graduate in medicine of a university; (3) no fellow or member of the College shall officially, or under colour of a benevolent purpose, offer medical aid to, or prescribe for, any patient whom he knows to be under the care of another legally qualified medical practitioner. See *Medical Directory*, published annually by Churchill, London.

Physic Nut, or *Curcas purgans* (sometimes placed under *Jatropha*, q. v.), is a soft-wooded shrub or small tree belonging to *Euphorbiaceæ*, a native of tropical America, and now generally cultivated in all hot countries for the sake of its seeds, which yield a purgative oil commonly employed in native medicine, and used also for burning in lamps, for cloth dressing, and as a substitute for linseed oil. The fruit is about the size of a filbert, containing three seeds, the kernels of which have a nutty pleasant taste, but are injurious, or even dangerous, if eaten in quantity. The leaves are used for fomentation; the juice of the young buds, which dries into a brilliant transparent substance of the colour and consistence of shellac, as an application to cuts and ulcerated wounds; and the bark of the root externally for rheumatism. By the Chinese the juice is made into a black varnish by boiling it with oxide of iron. The above species is generally called English P. N., to distinguish it from the French P. N. (*C. multiflorus*), also a native of tropical America, and furnishing an oil of like purgative properties called Pinhoen oil.

Physics, or **Natural Philosophy**, is the science which treats of the laws that regulate all natural phenomena. It therefore lies at the basis of all true accurate knowledge of such branches of science as chemistry, geology, biology, and physiology. Much detailed knowledge of facts may, indeed, be acquired in these various departments without any sure acquaintance with the laws of P.; but in such case, a comprehensive grasp of the principles underlying the special branch of science is impossible. P. is best defined, perhaps, as the science of Energy (q. v.). It deals with matter and the properties of matter only in so far as they are intimately associated with the transformations of energy. The study of matter as matter is the province of chemistry, which in its turn recognises energy solely as affecting matter and its combinations. P. and chemistry, then, differ only in the relative importance which each attaches to these great *existences* of nature—energy and matter. Geology confines its investigations to the materials forming the earth's crust, and to the agencies which are modifying these. In physical geography it joins hands with pure P.; in mineralogy and petrology it touches on chemistry; and in paleontology it has much in common with biology. Biology concerns itself with life, and really includes physiology, which might be defined as the P. of life or the dynamics of life. Energy, then, is the subject-matter of P., and consequently the great law of P. is that grand generalisation of the 19th c.—the conservation of energy. The history of the science, viewed in the light of this principle, beautifully illustrates the gradual development of law out of chaos. Among the ancients, a deity was supposed to lurk behind every phenomenon. But this superstition soon gave way as experience grew and knowledge deepened; and we find Lucretius referring all the actions of nature to the molecular structure of matter, dowering his atoms with properties at once ingenious and wild. The world, however, was not ready for such generalisation; and no safe generalisation can be made unless founded on experience or logical induction from experience. All down through the ages we find experiment leading to the establishing of empirical laws; these directed the investigator along paths which gradually joined and converged to one great centre, while this great centre, once gained, disclosed other lines of inquiry, which led to truths more startling than man had ever before conceived. The labours of Copernicus, Brahe, Galileo, and Kepler suggested to Newton the universal law of gravitation, and resulted in the establishment of the whole of

dynamical science with a fulness and exactness which has never been excelled. Newton's experiments on light, and Huyghen's theory, developed in the hands of Young and Fresnel into the beautiful undulatory hypothesis; while the early work of Rumford and Davy, supplemented by the experiments of Joule, Colding, and Mayer, and the mathematical analysis of Rankine, Thomson, and Clausius, grew by gradual process into the united system of thermodynamics. The theory of exchanges, established by Prevost, Stewart, and others, for heat radiations, was extended by Stokes, Kirchhoff, and Bunsen, to explain the dark absorption lines of the solar spectrum, first observed by Wollaston and mapped by Fraunhofer. Ampère's investigations into the mutual effects of voltaic currents, the discovery by Oersted of the fundamental fact of electromagnetism, and the brilliant researches of Faraday into electric and magnetic induction, have been gradually linked together by Weber, Helmholtz, Thomson, and Maxwell, so that now all the correlations of electricity and magnetism are recognised as instances of transformations of energy regulated in all cases by the conservation principle. Newton all but enunciated this principle in its most general form. Expressed in mathematical language, it shaped itself under the hands of Laplace and Lagrange into a complete system of celestial dynamics. It was a development co-existent with the growth of thermodynamics, but immeasurably more extensive, and now it embraces in its wide grasp the whole circle of the sciences. Thus, though the conservation of energy is common to all branches of scientific inquiry, it is peculiarly the property of P., which is the nucleus of all science.

Physiognomy (Gr. *physis*, 'nature,' and *gnōmē*, 'a means of knowing'), the study of the face as an index to character and mental disposition. The writings of Lavater (q. v.) contain a full exposition of this study, which was begun by Della Porta of Naples in 1615. The face, like the body at large, sympathises to a great extent with the mental disposition of individuals and of race. As the portion of the frame more especially concerned in the 'expression of the emotions,' the face may be regarded as being intimately related to the mind and intellect, and to reflect to a greater or less degree the mental emotions. Then, also, types of facial conformation may be noted to accompany certain types of habit, race, &c. The study of P. reveals thus much, and in a general fashion may be said to possess a standing of a higher kind than Phrenology (q. v.) as a means of determining character. But its more special applications to determine the innate phases of human character, or to invariably show the working of the emotions, have not been successfully carried out. Darwin's work on the *Expression of the Emotions* may be said to present the most succinct view of the modern relations of P.; facial conformation being shown to arise from the special use of certain muscles over others.

Physiology (Gr. *physis*, the 'nature' of anything, and *logos*, an 'account' or 'description'), the department of Biology (q. v.) which investigates the *functions* of living beings. P. is thus the companion science of Morphology, which deals with the *structure* or form of organisms, and a knowledge of morphology and P. constitutes the only sure basis for the classification and arrangement of animals and plants. The study of P. may be said to include the investigation of three great functions, viz., *nutrition*, *reproduction*, and *innervation*—this last having reference to the working of the nervous system. *Nutrition* includes the processes by which the individual living being maintains its growth, whilst *reproduction* refers to the perpetuation of the species or race. *Human P.* is sometimes named the *Institutes of Medicine*, inasmuch as this branch of medical study forms the basis of rational medicine. The knowledge of the healthy processes or functions of the body, in other words, enables the physician to understand the nature of abnormal or diseased action. P. was first taught in ancient times as a branch of philosophy by Plato and other scholars. The ancient physicians (Hippocrates, Galen, Erasistratus, &c.) necessarily embodied observations on the structure and functions of the human body in the course of their studies in medicine, but only within a comparatively recent date has the science been specially studied. Harvey's discovery of the circulation in 1620 gave a great impulse to it. Haller's influence was also well marked, and John Hunter may be said to have advanced it in no slight degree.

Physophorida, an order of *Hydrozoa* represented by the *Physalia* or 'Portuguese men-of-war,' by the genera *Veitella*

(q. v.), *Porpita*, &c. These are free-swimming organisms which swim on the surface of the sea through the agency of a *pneumatophore* or float. Each organism consists of several polypites, and has long tentacles and thread-cells or stinging-cells.

Physostom'ata, a division of *Teleostean* fishes (otherwise named *Malacopteri*) represented by the eels, herring, salmon, pikes, &c. In this group the air-bladder opens into the throat by means of a *pneumatic duct*, and the fin-rays are 'soft' or many-jointed. The scales are *cycloid*, although some of the fishes included in this group are destitute of scales, and in one or two cases *ganoid* scales may be developed. Ventral fins may be absent, as in the eels (*Apoda*), and when present, they are abdominal in position (e.g., salmon).

Phytolac'ca, the type genus of *Phytolaccaceæ*, consisting of about ten species of strong herbs or shrubs, distributed throughout the tropical and sub-tropical regions of both hemispheres, but most abundant in the western.

Phytolacca decandra.

After boiling, the young shoots become harmless, and are eaten as asparagus. *P. dioica*, known as *Bella sombra*, is a fast-growing tree, with a thick-based trunk, and soft, coarse-grained, fibrous wood, indigenous in La Plata and Brazil, and used as an avenue tree in Spain, Gibraltar, and Malta. In some parts of India the leaves of *P. acinosa* are eaten as a vegetable, while in the West Indies the berries of *P. octandra* serve as a substitute for soap.

Phytology (Gr. *phyton*, 'a plant,' and *logos*, 'a description') is that part of Botany that treats of plants in general.

Phytozo'a (Gr. *phyton*, 'a plant;' *zōon*, 'an animal') is a name given to certain fertilising organisms in ferns, seaweeds, fungi, and other of the lower order of plants, but they are now generally called *antherozoids*, or better still *spermatozoids*, as they perform male functions identical with the pollen in phanerogamous plants, and with spermatozoa in the animal kingdom. They are formed in a cell called an *antheridium*, from which they escape as minute motile bodies, and obtaining entry into the developed female cell or *oosphere*, the reproduction of the species is secured. These movements are effected by filaments called *cilia*, but the internal force by which the motion is performed has not been ascertained. For a long time they were considered to be endowed with animal life.

Piacen'za (Fr. *Plaisance*, the *Placentia* of the Romans), a city of Northern Italy in the province of the same name, lies on the right bank of the Po (here crossed by an iron bridge), 43 miles S.E. of Milan by rail. It is the seat of a bishop, and is fortified with thick walls and a citadel of great strength. The streets are very broad, and the principal of them, the Stradone Farnese, is one of the finest in Italy. The largest square is the Piazza de' Cavalli, in which stand bronze equestrian statues of the Dukes Alessandro and Ranuccio Farnese, erected 1620-24. The cathedral, a Romanesque-Lombard edifice, founded in 1122, contains some fine frescoes by Ludovico Caracci and Guercino, and has a crypt borne by 100 columns. There are other interesting churches, several hospitals, a theatre, and a public library of 40,000 vols. It was for the church of St. Sisto (1499-1511)

here that Raphael about 1518 painted his masterpiece, the Sistine Madonna, which is now at Dresden. There are slight silk and linen industries, and some trade in grain, wine, cheese, &c. Pop. (1874) 34,985. *Colonia Placentia* was founded by the Romans in 218 B.C., to intercept the advance of Hannibal. Twenty years afterwards it was plundered and destroyed by the Gauls, but was soon rebuilt and fortified by the Romans. During the Middle Ages P. was governed by various noble families, the Scotti, Torriani, and Visconti, while in 1488 it was plundered by Francesco Sforza, and never entirely recovered from the blow. It came finally into the possession of the Farnese (1545), under whom it was united to Parma. Church councils were held here in 1095 and 1132.

Piana dei Gre'ci, a town of Sicily, province of Palermo, 8½ miles S. by W. of Palermo. It was founded in 1488 by an Albanian colony, but the inhabitants, noted for their predatory habits, are losing their peculiarities of language and custom. The Greek church is adorned with fine frescoes. Pop. (1874) 7714.

Pia'no (Ital. 'soft'), a direction in music, abridged *p.*; pianissimo, *pp.* 'as soft as possible.'

Pianoforte (Ital. 'soft-loud'), a musical stringed instrument with a keyboard, deriving its name from its capability of producing gradations of tone, its strings being struck by hammers instead of being twanged by quills or other plectra, as in the instruments of similar construction formerly in use. We may trace the origin of the P. from the dulcimer through such instruments as the clavicytherum (the oldest keyboarded instrument; the clavichord or clavicord, which had strings of wire instead of gut; the clavicymbalum, or 'dulcimer with a keyboard,' the strings of which were made of steel wire; the virginal or spinet; and the harpsichord or clavier, which enjoyed a long reign of popularity, and for which many of the best compositions of Handel, Bach, Haydn, and Mozart were written. The compass of the harpsichord, which was in shape like a grand piano, was from three to five octaves. It had originally two strings in unison and one in octave for each note, and afterwards three strings in unison. Double harpsichords, with two rows of keys acting on two sets of strings, were common, many of Bach's thirty variations being written for such instruments. Harpsichords were constructed with more than twenty modifications to imitate the sounds of various instruments; but with all the complications of stops, springs, extra rows of keys, &c., it was found impossible to produce a pianoforte shading. Moreover, the quills in a well-used instrument required continual renewal. The invention of the P. has been variously claimed for Schröter, a German organist; Mairus, a French harpsichord maker; Father Wood, an English monk at Rome; and Bartolomeo Cristofali, a maker of Parma, who is supposed to be most justly entitled to the honour. A number of foreign makers settled in London in the 18th c., and to them and their English brethren is due the present high perfection of the mechanism of the instrument. Among the list of eminent makers are Broadwood, Kirkman, Erard, Stodart, Clementi, Collard, Hopkinson, &c. The compass of the earliest pianofortes was five octaves. It is now usually seven octaves. The older instruments were provided with *sordini* (small pieces of wood tipped with cloth which the performer might use in lessening the vibration), hence the directions in music *con* (with) and *senza* (without) *sordini*. The dampers in modern pianofortes have a similar effect. The right-hand pedal (used in 'senza sordini' passages) raises the dampers, which otherwise fall on the strings immediately after the hammer has struck them. The left-hand pedal, producing the effect of only one string, is to be used when the words 'una corda' occur, the result being a genuine piano in tone; but its frequent use puts the instrument out of tune. There are four principal parts in a P.—the framework, the sounding-board, the mechanism, and the case. The frame is the skeleton, across which the strings are stretched by means of pins. It is made of wood or metal, and wrought-iron bars and plates are used for strengthening purposes, so that it may bear an enormous tension, amounting in a modern grand piano to nearly ten tons. Messrs. Hopkinson adopt a complete cast-iron frame in one piece, whilst the firm of Kirkman use steel. A metal frame produces the most powerful and brilliant tone, but that of wood is the sweetest. The sounding-board is made of wood. By the mechanism or action is meant the contrivances, the lever, button, check, damper, &c., affecting the hammer and the keys, and although the principle

is similar, the varieties in manufacture are almost endless, nearly every maker having some peculiar and ingenious system. At least 150 different patents have been obtained for different actions, in which the mode of striking the strings, and the control of the sounds by check and repetition apparatus are variously managed. By the invention of upright (as in the cottage P.) instead of horizontal action, a P. can be made whose mechanism is confined in one-fourth of the depth of a grand piano. The strings of the P. are of varying length and thickness. In older instruments the strings were all parallel and in the same plane, but now the longer strings are often arranged obliquely. The number of strings varies according as the instrument is a bichord or trichord. In so-called trichords the lowest octave notes have single strings of very thick steel wire covered with a double coil of fine brass wire; the strings of the next octave are similarly covered with a single coil, then one or two octaves have two plain steel wires, and the remainder of the notes in the instrument, including the middle and upper part, three plain steel wires. Among the different kinds of pianos are the grand (known in Germany as *flügel* from its wing-like shape), the cottage, the boudoir, the concert-room, the drawing-room, &c. In the manufacture of elaborate pianofortes, there are as many as 4000 distinct pieces, separately fashioned, made of many different varieties of wood, metal, and other materials.

The P., being the most charming and suitable single instrument for private use, being capable of producing the greatest variety of harmony, like a miniature orchestra, and invaluable for the accompaniment of vocal music, is considered an almost indispensable piece of household furniture, and this universal demand gives employment to thousands of workmen in the great cities of Europe. The English action is being rapidly introduced into Germany, and the London makers still rank pre-eminent for the excellence of their productions. In America, the manufacture has been carried to great perfection by Steinway, Chickering, Lindeman, Steck, &c. Beethoven, Mozart, Weber, Mendelssohn, Schumann, &c., have written some of their most beautiful pieces for the P., while such composers as Chopin, Hummel, Kalkbrenner, and Heller have almost confined themselves to this instrument. The long roll of illustrious performers on the P. contains such names as Moscheles, Thalberg, Liszt, Halle, Von Bulow, Pauer, and Rubinstein, and Mesdames Pleyel, Schumann, and Arabella Goddard. See Rimbault's *P., its Origin, Progress, and Construction* (Lond. 1860), Paul's *Geschichte des Klaviers* (Leips. 1868), Blickthor & Gretscher's *Lehrbuch des Pianofortebaus* (1871), and Brinsmead's *History of the P.* (last ed. 1877).

Piarists (Lat. *Patres Piarum Scholarum* or *Scalopini*), a religious order, devoted to the instruction of the people, and founded in 1599 by the Spaniard St. Joseph Calasanz (1556-1648). They were confirmed in 1617 by Paul V., and again in 1612 by Gregory XV., when they were raised to a congregation of 'Regular Clerks of the Pious Schools.' The habit and constitution of the P. resemble those of the Jesuits, but unlike the latter the P. have never mixed in politics. Hungary and Poland have been the chief scene of their labours, and they have also founded colleges in Bohemia, Moravia, Silesia, &c.

Piassaba, Piassava, or Piaçaba, is a stout woody fibre, obtained in Bahia, from the leafstalks of a palm called *Attalea funifera*. After the withering of the leaf, the petiole remains attached to the stem by its sheathing base, and as the decay of its cellular matter takes place, the fibrous portion is liberated, ultimately hanging down in masses of considerable length. The natives make it into ropes, but the great use for which it is imported into European countries is for manufacture into brooms and brushes, particularly those used for scavenging purposes. Para P. is a finer and more valuable kind, obtained from *Leopoldinia P.*, a Brazilian palm. See *ATTALEA* and *COQUILLANUTS*.

Piat'ra, an old town of Moldavia, Roumania, on the W. bank of the Bistritza, an affluent of the Sereth, about 40 miles N. W. of Iakán, a station on the Sereth valley railway. It has paper-mills, and one of the oldest churches in Moldavia. Pop. 20,000.

Pias'tre (Ital. *pietra*, 'a thin plate of metal,' Gr. *emplastron*, 'a plaster') is the Italian name of a silver coin, first used in Spain, where it is called *peso duro* or simply *duro*, but afterwards adopted in Spain, Turkey, and the Spanish Republics of the New World. In Spain the P., better known as the Spanish dollar, is equal to about 4s. sterling. Under Turkish mis-govern-

ment, however, the coin has sunk to a mere fraction of its original value, and is at present worth from 1½d. to 2½d., and the English sovereign is considered equivalent to the piece of 100 piastres.

Piatt'i, Alfred, violoncellist, was born at Bergamos, in N. Italy, in 1825. He received his first lessons in music from Zanetti, after which he was a pupil of Merighi at the Conservatorio of Milan. After obtaining a high Continental reputation, he took up his residence in England in 1846, where he has never had a rival as a performer on the violoncello, particularly in chamber music. He has composed some excellent music, including *Un Passtempo Musicale*, *Mazurka Sentimentale*, &c. One of the best of his songs is *The Swallow*, sung with great success by Mr. Santley.

Piaz'za (Italian *piazza*, 'square, market-place'), an uncovered space enclosed by buildings.

Piaz'za Armeri'na, a town of Sicily, province of Caltanissetta, on the left bank of the Terranova, 17 miles E. by S. of Caltanissetta. It has an episcopal palace, several good churches enriched with pictures, and many fine villas. Its trade is in grain, wine, oil, chestnuts, and walnuts. Pop. (1874) 20,310. P. is said to have been founded by Greeks from Platea.

Piaz'zi, Giuseppe, a celebrated Italian astronomer, was born at Ponte, in the Valtellina, 16th July 1746. He was originally destined for the Church, and joined the order of the Theatins at Milan in 1764. He had early shown an extraordinary aptitude for mathematical studies, which he continued to cultivate under such renowned teachers as Tiraboschi, Lesueur, and Jacquier, and he was soon called to a professor's chair at Genoa. Here his openly avowed preference for the philosophy of Locke and Condillac exposed him to much petty persecution, to save him from which his friend Pinto, the grand-master of the Dominicans, transferred him in 1770 to the Chair of Mathematics in the newly founded university of Malta. After remaining here some years he was sent to Ravenna, where he taught philosophy in the College of the Nobles. Thence he passed to Cremona in the capacity of a preacher-in-ordinary, and shortly afterwards to Rome, where he filled the Chair of Dogmatic Theology in the college of San Andrea della Valle. By the advice of Jacquier, who used to employ him to verify his calculations, P. accepted, in 1780, the Chair of Mathematics at Palermo. Having obtained from the Government permission to establish an observatory here, he visited France and England in order to take advantage of the most recent improvements in the construction of his instruments. On his return to Palermo he superintended the building of the observatory, which was completed in 1789. In 1792 he published the first results of his observations, which embraced the correction of various errors regarding the obliquity of the ecliptic, the aberration of light, and the parallax and movements of the heavenly bodies. The praises which this work received from all quarters induced P. to undertake a general catalogue of fixed stars, which he published in 1803, and which was crowned by the Institute of France. In 1801 he greatly added to his fame by the discovery of a new planet, which he named Ceres, between Mars and Jupiter. In 1814 he published a second and much augmented catalogue of fixed stars (containing 7646), a work which was again crowned by the Institute. P. died at Naples, 22d July 1826. Besides his greatest work, *Lezioni di Astronomia* (2 vols. Palermo, 1817) and the star catalogues referred to, he also published *Della Specola Astronomica di Palermo* (3 vols. fol. 1792-1806); *Sull'Orologio Italiano ed Europeo* (ibid. 1798); *Risultati delle Osservazioni della nuova Stella scoperta, il 1° Gennaio* (ibid. 1801); *Codice Metrico Siculo* (1812); *Ragguaglio dell'Osservatorio di Napoli* (Naples, 1821). See Scroliani's *Elogio del P. Piazzi* (Pal. 1826).

Pi'broch (Gael. *probaircachd*, 'the pipe summons'), a piece of military music played on the Highland bagpipe. The term has also been erroneously applied by Lord Byron and others to the instrument itself. It is said that every clan had its own P. The music, harsh in tone and martial and defiant in character, has often fired the patriotic fervour of the Highland troops and led them on to battle. It rallied the clansmen at Quebec and sounded the great deliverance of Lucknow. The oldest known P. 'The Battle of Harlaw' was probably composed a considerable time after the struggle between the Lord of the Isles and the Earl of Mar (1411), as there is no mention of the bagpipe in the poetical account of the battle. Such instruments are re-

arded to have formed part of the Scotch military music at the time of the battle of Balrinnies (1594).

Pica. See TYPES AND TYPEFOUNDING.

Picardy (*Picardie*), an old province of N.E. France, bounded by the Netherlands, Champagne, Isle-de-France, Normandy, and the English Channel and Straits of Dover. It included the present department of Somme, with parts of Pas-de-Calais, Oise, and Aisne. P. came early under the power of the Franks, whose kings at first fixed their capital at Amiens, the chief town. In 1157, Philip of Elsass, Count of Flanders, obtained P. as the dower of his wife Isabella. On their decease it became a part of France.

The P. dialect of French is historically famous. It was formed by a mixture of the aboriginal Celtic of Gaul with Latin, and was not greatly affected by the conquest of the Franks, but betrays the influence of a later Teutonic conquest, that of the Normans, in numerous words and grammatical forms. The names of many towns, villages, and hamlets are still Norman. The dialect of P. is one of the two great branches of the *Langue d'Oïl* (see FRENCH LANGUAGE AND LITERATURE). It is rich in metrical romances, fabliaux, chansons, proverbs, satires, and rebuses. Several of these have been published. See Gicgoire d'Essigny, *Mémoire. . . . sur l'Origine de la Langue Picarde* (Par. 1811), and d'Abbé G. Corbier, *Glossaire du Patois Picard Ancien et Moderne* (Amiens, 1851).

Picci'ni or Piccinn'i, Nic'olo, a composer of extraordinary fertility, born at Bari, Naples, in 1728, studied for twelve years at the Conservatorio de St. Onofrio under Leo and Durante. On leaving this institution in 1754, he produced his first opera, *Le Donne Dispettose*, followed by shoals of similar works, among the best of which were *Alessandro nell'Indie* (1758) and the graceful *Buona Figliuola* (1760). He visited Paris in 1778, where he produced *Roland* (1778), *Atys* (1780), *Iphigène in Tauride* (1781), and *Didon* (1783), with such success that many critics pronounced him superior to his great contemporary Gluck, a verdict which posterity has scouted. He died at Passy, 7th May 1800. P. wrote over 150 operas, and numerous oratorios and cantatas. See Guingenc, *Notice sur la Vie et les Ouvrages de P.* (Par. 1800); Fétis, *Biographie Universelle des Musiciens* (new ed. 1878).—**Luigi P.**, a second son of the preceding (born 1766, died 1827), had also some musical talent, and composed a number of operas, &c., now forgotten.

Picc'olo-Flute, a small flute playing music an octave higher than written, with a compass of from D to A, its intermediate notes being the best. It is used by composers for striking effects, but requires moderate and judicious treatment from the shrillness of its tone. The organ stop called 'piccolo' is made of wood, and is two feet in length.

Piccolomini, the name of an old and still existing Italian family, which as early as the 15th c. possessed lands near Siena. The last P., Enea Silvio (Pope Pius II.), adopted the sons of his sister, Laudomia Todeschini, who founded the lines of P. of Aragon, the dukes of Amalfi and of Montemarcano, and the Princes of Valle. To this Todeschini-P. family belonged Pope Pius III.—**Ottavio P.**, in the third generation from Caterina, sister of Pius II., was born in 1599, served first at Milan, and commanded the regiment which the Grand Duke of Tuscany sent to the succour of Ferdinand II., and to which was due the death of Gustavus Adolphus at the battle of Lutzen, 1632. In 1634 he served in Bohemia in the army of Wallenstein, who confided to him his treasonable designs, which P. betrayed to the Emperor. He distinguished himself at the battle of Nordlingen, and in the campaigns of Swabia and Franconia, and in 1635 was sent into the Netherlands with 20,000 men to aid the Spaniards. He succeeded in driving out the French, but was not so successful with the Dutch. He was recalled in 1640 to defend the empire against Baner and the victorious Swedes, and in 1641 gained a marked advantage over them at Neuberg, but was defeated subsequently in Silesia by Torstensohn. In 1643 he passed into the service of the King of Spain, who sent him to the Netherlands; but he failed to effect anything with an army dispirited by the terrible defeat at Rocroi (q. v.). P. was re-

called by the Emperor in 1648, and appointed field-marshal, but the peace of Westphalia speedily put an end to the war. He was sent subsequently as plenipotentiary to the Congress of Nürnberg, and raised to the rank of a Prince of the Empire. He was decorated by the King of Spain with the order of the Golden Fleece, and granted the duchy of Amalfi. He died childless at Vienna in 1656, consequently the Max P. of Schiller's *Wallenstein* had no historical existence.

Piccolomini, Marietta, an operatic singer, born at Siena in Tuscany in 1835. Coming to England with a great Italian reputation, she made her first London appearance as 'Violetta' in *La Traviata* (specially written for her by Verdi) in 1856, and achieved a great success in this country. In 1861 she married, and withdrew from professional life at the early age of twenty-six. Among her best characters were 'Lucia di Lammermoor' and 'Zerlina' in *Don Giovanni*.

Pichegru, Charles, a famous French general, was the son of a small farmer, and was born at Arbois, 16th February 1761. He received his education at Brienne, where he showed great aptitude for mathematics, and prepared himself for the life of a monk. In 1783, however, he entered an artillery regiment, and speedily rose, after the outbreak of the Revolution, through all grades until in 1793 he became commander-in-chief of the army of the Rhine. Having formed a junction with Hoche at the head of the army of the Moselle, P. operated against the Austrians and took Gernersheim, Speyer, and Worms. On the 7th February 1794 he superseded Jourdan in the army of the north, and made a brilliant campaign in Holland. Returning to Paris, 1st April 1795, he suppressed the insurrection of the Faubourgs, but shortly left for the Rhine, where he captured Mannheim. But his political opinions had undergone a change. Success made him a Royalist, and, bribed by the Bourbons, he permitted himself to be defeated at Heidelberg. In 1797 he was returned to the legislature, of which he became president, but his intrigues were again unmasked, and he suffered transportation to Cayenne. Escaping from thence to England, he threw himself with zeal into a conspiracy against the First Consul, was captured in Paris, lodged in the prison of the Temple, where he was found strangled, 5th April 1804. There is nothing noble in P.'s character, and his fate, whether it was suicide or assassination, excites no sympathy. Deep-dyed in treason to his country, it is a paltry merit that he became a royalist, and wished to get rid of Bonaparte. See Montgaillard, *Mémoires concernant la Trahison de P. dans les Années III., IV., et V.* (Par. 1804); Cassier, *Vie du General P.* (Par. 1814); Treilhe, *La Vérité dévoilée par les Temps* (Par. 1814); Savary, Duc de Rovigo, *Mémoires sur la Mort de P.* (Par. 1825); Pierret, *P., son Procès et son Suicide* (Par. 1826).

Pichin'cha, a S. American volcano, 11 miles N.W. of Quito (q. v.). It has several peaks, the highest of which is 15,924 feet above the sea. The last serious eruption occurred in 1660, but since 1867 P. has emitted smoke and ashes.

Pichler, Karoline (*née von Greiner*), a German novelist, was born at Vienna, September 7, 1769. She received the most careful education, and, encouraged by Denis, Alxinger, and Haschka, who frequented the house of her parents, early devoted herself to poetry. She was married in 1796 to Councillor Andreas Pichler, and some years afterwards commenced to publish novels. Marked by force and elegance of style, and containing much fine description, they were very well received, but they are now little read, as they are frequently prolix, while the characters are not always well developed. Her chief work is *Agathos* (Vienna, 1808), a philosophical romance in which the beneficial effect of Christianity on civilisation is portrayed. It was written in opposition to the misrepresentations of Gibbon. Her other works were, *Idyllen* (1802); *Lenore* (1804); *Ruth, ein Biblisches Gemälde* (1805); *Erzählungen* (1812); *Die Grafen von Hohenberg* (1814); *Frauenwürde* (1819); *Die Belagerung Wiens von 1683* (1824); *Die Schweden in Prag* (1827); *Friedrich der Streibare* (1831); *Zeitbilder* (1840); *Denkwürdigkeiten aus meinem Leben* (1844). P. died at Vienna 9th July 1843. Her complete works were published at Vienna 1822-45 in 60 vols.

Pichurim Bean or Sass'afra Nuts are the commercial names for the cotyledons of the seeds of *Nectandra Pichury*, a tree of the Amazon district, belonging to the natural order *Lauraceæ*. They were formerly used as astringents and tonics,

but have more recently come into request for flavouring chocolate in substitution of vanilla, being so much cheaper. The flavour resembling that of the nutmeg, the name 'wild nutmeg' has sometimes been applied to them. They are not often imported, although there is a good demand for the article. An allied species (*N. cymbarum*) produces the Orinoco sassafras.

Pick'et (Fr. *piquet*), in military language, is a term variously applied. It denotes (1) in fortifications, a stake, shod at one end with iron, fixed in the ground for marking off distances, tying horses to, fixing tents, &c. Flags are attached when it is desired to make them visible from a distance. Small sharp-pointed pickets are also used for fixing gabions beyond a camp or fortress, and form useful defensive accessories. (2) The name P. is given to a small body of infantry or cavalry posted as sentinels in the front or flanks of an army. (3) The painful punishment of standing with one foot on a stake (picket) for a given time was so called. It was formerly common in the French army, but was abolished by Choiseul.

Pickles consist essentially of the soft parts of certain vegetables and succulent fruits prepared with and preserved in vinegar. P. are generally prepared and sold by manufacturers; but they can with ease be made of excellent quality on a domestic scale, and thereby with care any risk of deleterious admixture with salts of copper and other metallic compounds may be avoided. At one time it was a very common but most reprehensible practice to impart a vivid colour to green P. with verdigris or some other copper compounds. The presence of copper in P. is readily detected by allowing a bright steel knife to remain for a little time inserted in the suspected preparation, a film of copper depositing on the steel blade if that metal is present in solution. In preparing any P. the vegetables or fruits to be used are first well washed in pure water, and thereafter steeped in a strong salt brine. The material is next drained and dried, and placed in the jars or bottles in which they are meant to be preserved. For P. of the best quality, a sufficient quantity of hot strong malt vinegar is then poured over the substance; for lower qualities wood vinegar is used, and in that case a flavouring spice is frequently added. As soon as the jars or bottles have cooled down, they are corked up and tightly covered over to exclude as far as possible the air. It is of great consequence in the preparation of P. to avoid, as far as possible, the use of all metallic vessels and utensils, as vinegar and brine also act powerfully on metals, and the presence of poisonous metallic salt is often accounted for by this cause. Similarly in storing and keeping P. it is desirable not to use lead-glazed earthenware vessels. The fruits and vegetables which form the staple ingredients of P. in Great Britain are beetroot, the young pods of French or kidney beans, cabbage (white, purple, and red), capsciums, cauliflower, cucumbers and gherkins, eschallots, garlic and onions, mushrooms, tomatoes, and walnuts. Capers yield one of the most highly prized of all P., and olives, peaches, mangoes, limes, and melons are also treated and used as P. Mixed P. usually consist of onions, white cabbage, cauliflower, French beans, and gherkins.

Pico, an island in the central group of the Azores (q. v.), consists of a single volcanic mountain, the highest point of which (*El Pico*) is 7613 feet, and still emits smoke and lava. Area 254 sq. miles; pop. 36,000, mostly descendants of Portuguese. The island is fertile and in parts woody, and produces an excellent wine, of which some 25,000 pipes are exported annually.

Pico della Mirandola, Giovanni, an Italian philosopher and theologian, son of the Prince of Mirandola and Concordia, was born February 24, 1463, entered the University of Bologna at the age of fourteen, where he devoted himself chiefly to philosophy and theology, and was distinguished for his rapidity in acquiring knowledge. He next visited the principal schools of Italy and France, and mastered, in addition to Greek and Latin, Hebrew, Chaldee, and Arabic. Returning to Rome at the age of twenty-three, in the pontificate of Innocent VIII., he published 900 theses in logic, ethics, theology, mathematics, physics, and natural and cabalistic magic, which he offered to defend against all Europe. These famous theses, *De omni re scibili*, as P. styled them, *et de quibusdam aliis*, as Voltaire wittily added, apparently daunted the learned world, for no one had the courage to accept the challenge, but some envious

savants got Innocent VIII. to condemn thirteen of them as heretical. P. soon after settled at Florence, where he devoted himself to the twin studies of theology and Platonic philosophy. He died, November 17, 1494. P.'s contemporaries were filled with admiration of his genius. They called him the 'Phoenix.' In point of fact, however, he is perhaps the most striking instance in modern literature of superficial talent, conjoined with extensive reading. In a Civil Service competition he would probably have distanced all competitors; but had he lived and studied for a century, he would have added nothing to the store of human thought. A complete edition of his works was published at Bologna in 1496. Of these, the chief are *Conclusiones Philosophicæ*, *Cabalistica et Theologica*; *Apologia Concordiæ Comitum*; *Disputationes adversus Astrologiam Divinatrium* Libri xii.; *Heptaplus, id est de Dei Creatoris opere sex Dierum* Libri vii.; *De Ente et Uno Opus, unquo plurimi loci in Moise, in Platone et Aristotele explicantur*. The last edition of his works was that published at Basel, in 1601.

Pic'otee. See CARNATION.

Picrotox'in ($C_{12}H_{14}O_6$), a bitter vegetable principle forming small, colourless, stellate needles, soluble in alcohol and barely soluble in water. To it *Cocculus Indicus* owes its active properties.

Pic'ton, Sir Thomas, a distinguished British general, was the second son of John Picton, Esq., of Poyston, Pembrokeshire, where he was born in 1758. He entered upon his military career as an ensign in the 12th Regiment of Foot in 1791, was sent to the Antilles in 1794, and after the capture of Trinidad in 1797 he was appointed governor of that island, with the rank of colonel. In 1809 he assisted at the siege of Flushing, and after it had been taken was appointed governor. He afterwards took part in the Spanish War, and stormed the citadel of Badajoz in the face of a deadly fire. Appointed in 1815 to the command of the 5th Division of the army, P. saw a large part of his troops destroyed in the engagement at Quatre-bras, and he himself received a wound. Notwithstanding, he resumed active command at the battle of Waterloo two days after, and was killed by a cannon-ball as he charged the enemy at the head of his men, June 18, 1815. A monument to his memory was erected by command of Parliament in St. Paul's Cathedral.

Pictou, a flourishing seaport on the N. coast of Nova Scotia, is situated on a small and well-protected bay, 113 miles N.N.E. of Halifax by rail. Steamers ply from P. to Charlottetown, Quebec, and the ports of the Gulf of St. Lawrence. The principal trade is in coal, which is extensively mined in the vicinity. There are also large freestone quarries near the town. The manufactures include iron, leather, and tobacco. Pop. 3462.

Picts, a nation of northern Britain, whose origin, history, and fate were fiercely battled over by the 'learned' Pinkerton, the 'indefatigable and erudite' Chalmers, and their respective adherents, with 'the significant result,' says Burton, 'that the latest author (Robertson) coincided with the first critical inquirer into these matters, the venerable Father Innes.' More ink, indeed, has been spilt in the Pictish than in the Eastern Question, and Oldbuck and Sir Arthur were by no means the only men who lost their tempers over it. Now, when this Sphinx has grown old and unattractive, an Œdipus has at length arisen to solve her riddle in the person of Mr. Skene. His opinions, founded on the ripe knowledge of the present age, have passed unchallenged hitherto, and it will therefore only be necessary to summarise them briefly, leaving aside fantastic speculations on islands in the Danube, inhabited by a fifth part of the whole Teutonic race.

At the time of the invasion of Severus (208) the independent tribes whom Tacitus in the 1st c. had described as occupying that part of Britain known by the name of Caledonia (q. v.), and whom only the threatened invasion of Agricola had formed into a temporary confederacy, were found combined into the two nations of the Caledonii and Meatae. These may be safely identified with the Dicalidonæ and Vecturiones, into whom Ammianus Marcellinus divides the P. in 364. The name *Picti* itself first occurs in a panegyric addressed by Eumenius, professor of rhetoric at Autun, to Constantius Chlorus, the future emperor, on the occasion of his victory over Allectus (296). The speaker alludes to 'the Caledonians and other P.,' and clearly

regarded the latter as a long-established race, affirming that even in Cæsar's day the British had no more formidable foe than the half-naked P. and Scots. The etymology of the name P. has been keenly contested, many scholars, amongst them Trench, Pictet, and Taylor, deriving it from the Celtic *peicta* or *peith*, 'a fighting man,' whilst Pinkerton identified it, somewhat arbitrarily, with the Peukini of Pomponius Mela. Most probably it is really, what it would at first sight appear, the Lat. *picti*, 'the painted men,' corresponding to its Irish equivalent *Cruithneigh*. So at least the Romans undoubtedly employed it (cf. Claudian, *De Tertio Consulatū Honorii*, l. 54), and so Martial had applied the epithet *picti* to the British (*Ep.* xiv. 99). More vital than this question is that of the ethnological affinities of the P., which must be decided on the external evidence of statements made by their own and foreign writers, and the internal evidence of the scanty remnants of the Pictish language. Tacitus, from their red hair and large limbs, inferred that the Caledonians were of Teutonic origin (*Agr.* xi.), but he knew nothing of their language, and it is now commonly admitted that in outward configuration there was no essential diversity between the German and Celtic races. His opinion may therefore be dismissed with Max Müller's dictum that 'it is lost labour to try to extract anything positive from the statements of the Greeks and Romans on the race and the language of their barbarian neighbours.' That the P. were Celts we have the concurrent testimony of the entire literature of Wales, of Gildas, Nennius, and Bede, and of their own national record, the so-called *Pictish Chronicle*, a work of the 10th c. But did they belong to the Cymric or the Gaelic branch of the Celtic race? The best answer to this question may be obtained by comparing the five sole surviving Pictish words with their Cymric and Gaelic congeners, viz. P. *peanfahel*, 'head of the wall,' quoted by Bede, with the C. *penwald* and G. *cenail*, where only the initial *p* agrees with the Cymric; the prefix *nr*, occurring in thirty Pictish names preserved in the Irish *Nennius*, with the C. *gyr* and G. *gyr*; P. *scotofth*, 'a scholar,' quoted by Reginald of Durham, a 12th c. writer, with the C. *yscoltheic* and G. *sgolag*; P. *cartir*, 'a buckie,' given in Cormac's old *Irish Glossary* of the 9th c., with the C. *gwenll* and G. *dealg*; and lastly, the P. *dufer*, 'rich,' from a fragment of the *Pictish Chronicle*, with the C. *goludog* and G. *suobher*, where, *d* and *s* being interchangeable, the Pictish and Gaelic forms are seen to be identical. These five words, then, agreeing partly with Cymric, more closely with Gaelic, tend to show that Pictish, in Mr. Skene's own words, 'was not Welsh, neither was it Gaelic, but a Gaelic dialect partaking largely of Welsh forms.' And his view is confirmed, as well by certain lists of Pictish kings as by four topographical names peculiar to the districts held by the P., and met with nowhere else—*fit* (old *fitte*), 'a portion of land'; *auchter* (Gael. *nachter*), 'upper'; *for* (old *fothurr*), and *pu* (old *fothurr*), the two last both obviously Gaelic forms from their initial consonant *f*. The absence, too, of *pens* from Galloway, and the frequent occurrence of *bar* (Gael. *barr*, 'top or point'), and *ar* or *arie* (Gael. *aridh* 'a hill-pasture'), point to the same conclusion, against which Adamnan's statement has been sometimes urged, that St. Columba preached to the P. through an interpreter. But then, Adamnan also represents him as conversing freely with Bride, the Pictish king, and with the king's messengers, and a very slight dialectic variation will suffice to render a formal address unintelligible to the vulgar.

To gain a definite notion of the Pictish territories we must come down to the 7th c., when we find all the country N. of the Firths of Forth and Clyde, with the exception of the Scottish kingdom of Dalriada (Argyllshire), held by the Northern and Southern P., the boundary line between the two being the mountain range of the Mounth or Grampians. The seat of government seems to have alternated between these northern and southern tribes, but the latter were less purely Gaelic in race and language. They had also received the gospel from St. Ninian (q. v.) as early as 397, whilst the former were not converted by Columba (q. v.) till 565. S. of the Forth and Clyde were the P. of Lodonea (Berwick, Roxburgh, and the Lothians), whose name survives in Pentland, i.e., Petland or Pictland; and the Niduari P., whose district, coextensive with Wigton and Kirkcudbright, was known to the Welsh as Galwydel, to the Irish as Gallgaidel—the modern Galloway. And in Ireland itself, in Down and the southern half of Antrim, were the remnants of a Pictish tribe that had formerly extended over the whole of Ulster.

The chief events in the history of the P. from their first attack upon the Roman province in 360, with the subsequent raids of 387, 402, and 407, were their conversion alluded to above, their partial subjugation by the Northumbrian kings Oswald (634-42) and Oswin, his brother (642-70), their revolt (672), and invasion by Egfrid, who was defeated and slain at Dunnichen, May 20, 685. Restored to independence, they conformed in 710 to the Roman observance of Easter under their king, Nectan, who made Scone his capital, and in 731 was ousted from the throne by Angus mac Fergus. The latter, during a reign of thirty years, ravaged Dalriada (736), founded the monastery of St. Andrews, and united with Eadbert, King of Northumbria, in an unsuccessful attempt to subdue the Britons of Alclyde (756). Amongst his successors may be noticed Ciniod (763-75), the close ally of the Angles, Constantine (789-820), in whose reign the Scandinavian pirates first made their appearance, and Angus (820-32), on whose death Alpin the Scot claimed the Pictish crown, but was defeated and beheaded at Pitelpie, near Dundee. The overthrow of Eoganan by the Danes, together with the renewed ascendancy of the Columban clergy, assisted the downfall of the Pictish monarchy; and in 844, Kenneth mac Alpin, partly by right of conquest, partly in virtue of the Pictish law of female succession, obtained the kingdom of Scone. He, however, and his three successors, were still Pictish kings, their territory first changing the name Cruithenath or Pictavia to Alban under Donald in 889, from which date the P. as a nation may be said to disappear. Those of Galloway, surrounded by the Britons of Strathclyde, preserved their individuality longest, and appear at the Battle of the Standard (1138) as one of the divisions of the Scottish army. That they also retained their language as at least a patois is proved by Reginald of Durham, who states that in 1164 the *sermo Pictorum* was still spoken in Kirkcudbright, whilst Buchanan tells us that even in his day, i.e., in Queen Mary's reign, 'a great part of this country still uses its ancient language.' So that Henry of Huntingdon, writing in the 12th c., was clearly wrong in speaking of the P. and their language as something well-nigh fabulous, as too are those who seem to fancy that the present Scottish nation contains no Pictish element, a theory as baseless as that which should make no Celts in France, or infer from the mastery of High German as the literary dialect that the Low German races were being eliminated from the Teutonic empire. See Innes, *Critical Inquiry on the Ancient Inhabitants of Scotland* (1729); Pinkerton, *Inquiry into the History of Scotland* (1789); Chalmers, *Caledonia* (1807); Robertson, *Scotland under her Early Kings* (1862); Hill Burton, *History of Scotland* (2d ed. 1873); A. P. Forbes, *Life of St. Ninian*, in vol. v., and W. Reeves, *Life of St. Columba*, in vol. vi. of *The Historians of Scotland* (1874); and W. F. Skene, *Chronicles of the P. and Scots, and other Early Memorials of Scottish History* (1867), *The Four Ancient Books of Wales* (1868), and *Celtic Scotland* (1876).

Picts' Houses. See EARTH-HOUSES.

Picus and Picidae. See WOODPECKER.

Piddock. See PHOLAS.

Pie, the lowest fraction of the Indian currency, being $\frac{1}{16}$ th of an anna, or half a farthing in value, used only in accounts. The actual coin in use is the pice = 3 pies, or $\frac{1}{8}$ farthings.

Pie, a name given to numerous well-known culinary preparations, in the whole of which certain substances are baked or cooked within a crust or covering of prepared flour paste. Pies are of two chief kinds—meat pies and fruit pies; in the former almost all varieties of animal food may be used, in the latter nearly all varieties of fruit. The pies which have attained the most world-wide reputation are the Strassburg pies, *pâtés-à-fougeras*, in which the livers of geese in a condition of artificial fatty degeneration are employed. The veal and ham pies of Melton Mowbray, in England, are also well known throughout Great Britain.

Piedimonte d'Alife, a town of S. Italy, province of Caserta, on an affluent of the Volturno, at the base of Monte Cila, 20 miles N. by E. of Caserta, and 3 N.E. of Alife, the *Alife* of the Samnites, and now a mere village. P. is a thriving industrial town, with manufactures of excellent cottons, woollens, luns, paper, copper, &c. There are also large fulling and flour mills. Water-power is supplied by a torrent that issues from a cavern in the Val d'Inferno, a romantic gorge in the

vicinity. Pop. (1874) 7073.—**P. Etneo**, a town of Catania, Sicily, amidst wild volcanic scenery, near which is the famous chestnut tree known as the 'Castagno dei cento Cavalli.' Pop. (1874) 5140.

Piedmont (Fr. *Piémont*, Ital. *Piemonte*, 'at the foot of the mountain'), a former Italian principality, enclosed on three sides by the Alps and Apennines, and separated from Lombardy by the Ticino. It comprises, according to the present division, the provinces of Turin, Novara, Cuneo, and Alessandria, with an area of 11,299 sq. miles, and a pop. (1875) of 2,995,213. From the rich basin of the Po in the E., where rice, maize, and delicious fruits are abundantly produced, the country rises to the uplands, which yield excellent wine and silk, and finally to a bleaker region of forests and pastures. The Tanaro, Bormida, Clusone, the two Doras, Sesia, &c., all affluents of the Po, issue from valleys of singular beauty and fertility. The wild glens of the Cottian Alps in the W. of P. are still inhabited by the Vaudois or Waldensians (q. v.). In every valley are factories for the production of woollen and cotton stuffs, paper, silk, and cotton yarns, &c. Flour mills are numerous, some of the larger being provided with the latest improvements in machinery. Irrigation is conducted with great skill and under minute regulations. The Cavour Canal is one of the chief irrigation works. Turin, the largest town, was the frequent residence of the Dukes of Savoy, and from 1859 to 1865 capital of Italy. The earliest inhabitants of P. were Celtic and Ligurian tribes, who long withstood the influence of Rome. Indeed, the higher valleys were not completely subdued till the reign of Augustus. The dialect universally spoken even by the higher classes still retains traces of affinity to French. Thus, *pièce* is used instead of the Italian *piùere*, *on* for *uomo*, *cœur* for *cuore*, *sità* for *città*, *raison* for *ragione*, *piazza* for *piazza*. Travellers in P. find French quite as serviceable as Italian. The history of P. is closely interwoven with that of its dynasty. The House of Savoy (q. v.) as early as 1048 were sole possessors of Susa, Turin, and Aosta. In the beginning of the 12th c. the Savoy dominions, increased by the addition of Ivrea, Montferrat, Saluzzo, and Nice, were divided between the founders of the separate Savoy and P. lines. In 1367 the subdivisions were united by Amadeus V. the Great, and a law was passed settling the succession on the male line in the order of primogeniture. Amadeus VIII. received the title of duke from the Emperor Sigismund in 1416. In the Spanish War of Succession, Vittorio Amadeo II., boldly allying himself with Austria, threw off the suzerainty of France (1703), and obtained as a reward the Island of Sicily, which he was obliged to exchange for Sardinia in 1720. In 1713 he assumed the title of King, which was subsequently coupled with Sardinia. About this period P. itself was increased by large accession of territory. In 1798 the French deprived Carlo Emanuele IV. of all his Continental possessions. These, however, were restored by the Peace of Vienna, with the addition of Genoa. The name P. has been discarded, unless in a geographical sense, since 1860. See the official Report by Consul Colnaghi, Part iii., No. 13, June 1877.

Piedra Blanca, a town in the province of Catamarca, Argentine Republic, on the slope of an offset of the Andes, 170 miles N.N.E. of Rioja. Pop. 10,000.

Pier (from the Fr. *pierre*, a 'stone'), in architecture, is the name applied to the block of masonry between doors, windows, and other openings, as between the arches of a bridge. Norman and Gothic pillars are frequently called piers.

Pierce, Franklin, the fourteenth President of the United States of America, was born 23d November, 1804, at Hillsborough, New Hampshire, of which State his father, General Benjamin Pierce, was governor. He was educated at Bowdoin College, Maine, where he graduated in 1824, and where he formed an intimate friendship with Nathaniel Hawthorne, which lasted throughout his life. In 1827 P. was called to the bar, and practised with success in Hillsborough and Concord. He was member of Congress (1833-37), and of Senate (1837-42). After twice declining office under President Polk, he entered the army as a colonel of infantry in 1846, and on the outbreak of the Mexican War was appointed brigadier-general in the following year. P. was president of the New Hampshire Constitutional Convention (1850-51), and in 1852 he was elected President of the United States by 254 electoral votes against 42

104

for General Scott, the Whig candidate. His administration was a period of much political excitement, the most prominent events being the Gadsden Purchase, the repeal of the Missouri Compromise, the treaty for reciprocity of trade with the colonies of British America, and the publication of the Ostend Manifesto. It was during his term of office that the Kansas difficulties arose, which led to the war of 1861-65. P. was a zealous supporter of what is known as the State Rights doctrine, and his sympathies during the war were entirely with the Southern States. He died at Concord, October 8, 1869. See his biography by Nathaniel Hawthorne (1852).

Pierced, a heraldic epithet implying that a charge is perforated, displaying the field beneath. When the shape of the aperture is not given, it is presumed to be circular.

Pierre, Saint. See SAINT-PIERRE.

Pietà (Ital. 'piety,' 'affection for relatives'), a term applied in painting and sculpture to a representation of the Virgin Mary embracing the dead Christ, being the counterpart of the Madonna in which the mother holds the child in her arms. In St. Peter's at Rome is a P. by Michael Angelo.

Pietermaritzburg, commonly shortened to **Maritzburg**, the capital of the colony of Natal, is situated in 29° 41' S. lat., 30° 13' E. long. It derives its name from two of the Boer leaders, Pieter Retief and Gert Maritz, and was founded in 1843. P. occupies a remarkably fine site, on an elevated plain near the river Umgeni, is well laid out and substantially built. The water supply is unusually ample for South Africa, and the climate is good, though thunderstorms are very frequent. A railway to connect P. with Port D'Urban (q. v.), 54 miles distant, is being made. Pop. (in Jan. 1876) 7457, of whom 4290 were whites.

Pietists, a name applied in Germany to a class rather than a sect of religionists, who are distinguished by a preference for the practical rather than the doctrinal aspect of religion. Pietism resulted from a reaction against the hard and polemical phase which Lutheranism assumed after the struggle of the Reformation had become forgotten, and, as such, has had its counterpart in the history of every church. Its origin in Germany is ascribed to Johann Arndt's *Vom Wahren Christenthum* (1605), and the *Invitatione Fraternalitatis Christi* (1617) of Johann Val. Andree; but the chief impulse was given by the *Pia Desideria* (1672) of Spener (q. v.). The term was first applied in 1689 to three young *doctores* at Leipzig, who had all been disciples of Spener, and chief among whom was Francke (q. v.). They began to hold meetings, which they called *collegia pietatis*, and which excited the indignation of the authorities, who accused them of unsettling tendencies, of making religion consist of a pious sentimentalism, and of exaggerating the merit of good works, and compelled them to leave Leipzig. Francke repaired to Erfurt, but subsequently obtained a professorship in the new University of Halle, which now became the centre of evangelical religious life in Germany. After the death of Francke in 1727, pietism assumed a less amiable phase, its adherents becoming more spiritually exclusive and denunciatory in tone. The spread of rationalistic theology (*aufklärung*) did much to injure pietism, nor did all the attempts, from political motives, of the Prussian government to revive its simple and unquestioning spirit, give the movement anything of its previous strength.

Pietra Du'ra (Ital. 'hard stone') is a kind of mosaic work of hard stones characterised by brilliancy and variety of colour. The stones employed for the purpose are chiefly agate, chalcedony, carnelian, jasper, amethyst, lapis-lazuli, malachite, and occasionally variegated marbles. This costly and laborious art originated in Italy in the 16th c., and that country still maintains its excellence in the production of table-tops, &c., in P. D. The manufacture is also carried on in the imperial manufactory at St. Petersburg and in some parts of India (see INLAYING). The inland marble work of Derbyshire in England partakes of the nature of P. D.

Pietraperzia, a town of Sicily, province of Caltanissetta, near the left bank of the Salso, in a hilly region 6 miles S.E. of Caltanissetta. It has a trade in grain, almonds, pistachio nuts, sulphur, plaster-of-Paris, and lapis-lazuli, procured in the vicinity. Near it is an interesting old castle. Pop. (1874) 10,150.

Pietrasanta, a town in the province of Lucca, Italy, on a hill 2 miles inland, and 20 N. W. of Lucca. It is girt by a castellated wall, and has many fine buildings of the 14th and 15th centuries. P. is the chief place from which the Serravezza marble is sent to market. The vicinity produces much oil and wine. Pop. (1874) 13,227.

Piezometer, an instrument first constructed by Oersted, for measuring the compressibility of liquids. It consists of a glass bulb and stem open at the top. The liquid to be experimented on is introduced into the glass vessel so as not quite to fill it, and a globule of mercury is placed on the upper surface as an index. The P. is then set upright in a strong glass cylinder which is filled with water, and water pressure is applied by means of a tightly-fitting screw. The pressure is measured by the compression of a quantity of air contained in another glass tube, which is inserted with the open end downwards. Correction of course must be applied for the glass of the P.

Pig. See Hog and Swine.

Pigeon (Fr. *pigeon*, Ital. *pigione* or *pipione*; from Lat. *pipire*, 'to peep or cheep'), the general name given to a large number of birds included in the section *Columbide* of the order *Rasores*—this order including as its other representatives the true Gallinaceous birds, such as fowls, pheasants, partridges, &c. By some ornithologists the pigeons are represented as forming of themselves a distinct order, under the name *Columbe*. They differ in several important respects from the ordinary *Rasores*; e.g., their hinder toe is well developed, and is placed on the ground; their wings are more powerful; and their habits, with a few exceptions, are not those of ground-birds, their feet being of slender build and adapted for perching. The ordinary *Rasores* are, further, polygamous, one male mating it may be with numerous females; the pigeons, on the other hand, are monogamous, and, as a rule, pair for life. It is a noted fact that sometimes a surviving bird of a pair will refuse to mate with another, and may remain disconsolately single for a long period. No birds are more interesting to naturalists than the pigeons, since they serve, through the facts connected with their breeding and variation, to demonstrate some of the most important ideas connected with the 'origin of species.' Darwin has collected, in his *Animals and Plants under Domestication*, an immense number of facts showing that all the common, numerous, and widely different breeds of pigeons—e.g., the pouters, tumblers, carriers, and fantails, so different not merely in appearance but in the structure of their skeleton, in the number and arrangement of their tail feathers, &c.—have descended from the Rock P. (*Columba livia*); and thus, from a common stock, forms have been produced which, had they been submitted to a naturalist ignorant of their affinities, would assuredly have been pronounced by him distinct species. In the P. the bill is generally short, straight, and compressed, the nostrils being in a fleshy membrane at the base. The P. may be divided into the sub-family *Columbina* (including the most typical forms of P.) and that of the *Gourina* or Ground P. A third division is usually added, that of the *Didunculina*, represented by the genus *Didunculus*, including the tooth-billed P. of the Navigator's Islands. The *Columbina* have a long bill, narrow nostrils, long toes, and pointed wings. Of this group the genus *Columba* (including all the common pigeons) itself is the most typical. The bill has the membrane above the nostrils somewhat prominent and dilated, and the second quill is the longest. Other genera belonging to the *Columbina* are *Carpophaga*, represented by the Fruit P.; *Ectopistes*, including the Passenger P. (q. v.); *Lopholaimus*, represented by the top-knot P. of Australia; and *Turtur*, including the turtle-dove (*Turtur auritus*). The sub-family *Gourina* includes the Ground P., in which the toes are strongly made, the hinder toe being very long. The tail is of moderate length and rounded in shape. To this sub-family belong the genera *Ocyphaps* (crested pigeons); *Phaps* (bronze-wing P.); *Leucosarcia* (Wonga-Wonga P.); *Calenas* (Nicobar P.); and *Goura* (crowned P.). The sub-family *Didunculina* is represented by the tooth-billed P. (*D. strigirostris*), a near relative of the extinct Dodo (q. v.). In this sub-family the bill is arched, long, and hooked at its tip. The lower mandible has three distinct toothed processes, and the skin of the throat and around the eye is bare.

Law Regarding Pigeons in Great Britain.—Formerly in England none but the lord of the manor, or the parson, might erect a pigeon-house; and now it seems that this can only be lawfully

done by a freeholder, who may build a pigeon-house on his own ground. By 24 and 25 Vict. c. 96, any one unlawfully killing or wounding any house-dove or P., under circumstances which do not constitute larceny, is liable to a penalty, on summary conviction, of £2 above the value of the bird. In Scotland, shooting pigeons without consent of the owner is, by statute, theft; and a tenant is not entitled to shoot his landlord's pigeons on the plea of their being destructive to his farm.

Pigeon Pea is the W. Indian name for the produce of *Cajanus indicus*, a leguminous shrub, a native of the E. Indies, but now widespread in cultivation through tropical Africa and America. In India it is called the *Cajan* pea or *toor*, and there forms a pulse of general and daily use, being either roasted, used in soups, ground into meal, and with a mixture of wheat flour made into cakes, or the seed is split, forming the food called *dál*. The young and green pods are also eaten as a vegetable, and the leaves and the pods after the seed is removed are valuable as fodder. There are numerous varieties. Although naturally a perennial, in cultivation it is treated as an annual. The P. P. contains about 62 per cent. of starch, and 22 per cent. of nitrogenous substances.

Pigment, or Pigment Cells, in physiology the term used to denote colouring matters found in animal and plant bodies, and the cells within which such colouring matters are contained. Examples are seen in those of the *choroid coat* of the eye, but more typically in the skin of the frog. These latter cells are of branched form, and may be well observed in the web of the frog's foot. Under stimuli, such as light or electricity, the P. may be seen to become massed together in the body or centre of the cell leaving the processes of the cell empty, and in this fashion producing the blanched appearance of the frog's skin under the action of light. *Chromatophora* or *colour-cells* in chameleons, cuttlefishes, &c., produce the changes of hue in these animals by alterations in form and situation.

Pigments. See PAINTS.

Pike, a weapon formed of a lance or spear head mounted on a long ash stave, introduced into England at the close of the 15th c., and carried by a foot soldier, called a *pikeman*. It was originally the arm of the Swiss infantry, who usually fought in mass, presenting a serried line of steel. The P. was abandoned in favour of the bayonet in the reign of George II.

Pike (*Esox lucius*), a species of *Teleostean* fishes belonging to the *Malacopectera Abdominales*, or that section in which the ventral fins are abdominal in position. The P. is the type of a family (*Esoctidae*) in which the dorsal fin is set far back in the body; and in the P. genus itself, the body is long and the snout flattened, the teeth being very numerous, and borne by almost every bone entering into the composition of the mouth. The common P. is a well-known freshwater fish, attaining an occasional weight of over 50 lbs. An average weight is from 5 to 10 lbs. Its colour is an olive-brown, tinted with green above and silvery white below. It is exceedingly voracious, and is known frequently to seize ducklings and other birds and drag them beneath the surface of the water. The P. may live to a great age. It is caught by nets, ordinary lines, and by *trammel lines*, the bait of which is made to rest at a certain depth and runs out for some distance when the fish seizes it. P.-fishing usually extends from May to February, and November is regarded as the most favourable month. The P. spawns in spring, the young being sometimes known as 'jack' and 'lucet.' The Scotch name for the P. is 'gadd.' The name P. is also given to other fishes. Thus the Sea-P. is the *Belone vulgaris* or Garfish (q. v.), the Saury P. being the *Scorpaenopsis scorpaenoides* of zoologists. The Bony P. (q. v.) of N. America is a *Canoïd* fish (*Lepidosteus osseus*). Several species of true P. belonging to the genus *Esox* are found in N. American lakes.

Pike Perch (*Lucioperca sandra*), otherwise named the 'Giant Perch,' occurs in many European lakes and rivers, and may attain a length of 3 or 4 feet. Its colour is an olive-green banded with brown. It belongs to the family *Percidae*, and while agreeing with the perch in most of its characters, presents in its outward aspect a strong resemblance to the Pike (q. v.). The P. P. possesses two dorsal fins. It is named the *Sander* and *Sandai* in Germany, and *Schill* in Austria. An allied species (*L. Americana*) is found in N. American fresh waters.

Pike's Peak, a summit of the Rocky Mountains in Colorado, U.S., is 14,336 feet above the sea. The ascent is difficult, but is well repaid by the magnificent view to be obtained, which embraces the sources of four great rivers—the Platte, Rio Grande, Arkansas, and Colorado. It received its name in honour of General Z. M. Pike, who first described it in 1806. The district abounds in auriferous quartz, and has since 1859 been a favourite resort for gold-diggers.

Pila'ster (Ital. *pila'stro*), in architecture a square pillar attached to a wall, from which it projects a third, fourth, fifth, or sixth of its breadth.

Pil'chard (*Clupea pilchardus*), a Teleostean fish, attaining a size little inferior to that of the Herring (q. v.), and belonging to the family *Clupeide*, of which the latter fish is the type. The mouth is of moderate size, and, as in the herring, the scales are large, bright, silvery, and readily detached. Pilchards are caught in immense numbers in August and September on the Cornish coast. They are fished by means of *seine* nets, enclosing a shoal of pilchards after the fashion of a pocket, and being gradually drawn shorewards. They are removed from the 'seine' by another and smaller net known as the 'tuck-net,' and are packed in hogheads, each of which contains over 3000 pilchards. As many as 10,000 barrels have been filled in one day's successful fishing. These fish are chiefly consumed by Roman Catholic communities during Lent and other seasons of fasting. The spawning time of the P. is the month of October. It would appear probable that it does not leave the British coasts in summer, as was formerly supposed, but, like the herrings, merely retires to deeper water. In Scotland the P. is known as the 'Gipsy Herring.'

Pilcoma'yo, a river of S. America, is formed by the junction in 21° 35' S. lat. of the Suipacha and Pilaya, two streams issuing from the Bolivian Andes, and after a S.E. course of about 1200 miles, unites with the river Paraguay opposite Asuncion. The middle portion of the course of the P. is still very imperfectly explored, but many rapids, and a large marshy lagoon 185 miles in circumference, are known to exist. Its lower waters have been ascended by a steamer for 150 miles, and the least depth ascertained to be 4½ feet. Probably the P. will prove navigable by barges and canoes for 500 miles. Its banks are apparently fertile, but the hostility of the Indian inhabitants renders exploration dangerous.

Pile, in heraldry, a sub-ordinary, of a wedge-shape, issuing from the middle chief, and tapering downwards to the middle base, said to represent the piles used in building bridges, &c.

Pile'olus, a fossil genus of *Gastropodous* molluscs, the shells of which are of small size and of limpet-shape, and occur in the Lower Oolitic rocks. It belongs to the family *Neritide*.

Piles, in engineering, are strong pieces of timber, usually elm, fir, or beech, pointed and occasionally shod with iron, that are driven into marshy or loose soils to afford a secure foundation for buildings, piers, wharves, &c. These timbers vary in length from 20 to 40 feet, according to the depth at which a firm foundation exists, and in thickness they commonly measure from 12 to 15 inches square. Many cities, for instance, Stockholm and Amsterdam, are built in great part on P. Pointed cast-iron P. are sometimes substituted for those of timber. In either case the P. are driven into the earth by repeated blows from a great iron weight called a *ram* or *monkey*, which is raised by manual or steam-power to the top of lofty guide-posts, and then suddenly disengaged and allowed to fall with tremendous force on the head of a pile. Of late years, timber and cast iron P. have been provided with screw-points; these P. penetrate the soil by imparting a rotatory motion by means of levers fixed to the upper end. In some recent works of construction, subaqueous foundations for piers have been formed by employing hollow P. or cast iron cylinders in short lengths. They are sunk into the ground by removing the soil beneath them by inside operations. As one section is sunk another is bolted vertically on to it, and others are added as the work of excavation proceeds. When the solid rock is reached the jointed pile is formed into a solid column by filling in concrete or other material.

Piles, or **Hæmorrhoids**, are small tumours situated either within or at the verge of the anus, formed of enlarged vessels surrounded by infiltrated cellular tissue. *External* P. consist of

an enlarged vein or veins filled with clots, the skin and connective tissue being more or less thickened and inflamed when the veins become distended. There are also, generally, folds of loose integument around the anus in which no enlarged vessels can be detected. P. are caused by conditions which determine the blood to the part, or prevent its return, such as pregnancy, obstruction to the portal circulation, luxurious habits, sedentary employment, cold, wet, and too free purging. P. are also divided into *bleeding* and *blind* P., according as they are or are not accompanied with hæmorrhage. *Internal* P. are produced by similar causes; but they constitute a much more formidable malady, being frequently attended with copious and constant hæmorrhage during defecation. The tumours, when large, sometimes protrude even when the bowel is not acting, and they occasionally drag the whole end of the gut out of the anus, giving rise to prolapsus. *Internal* P. are generally situated close to the anus at a little distance up the bowel; but they are often partly external as well. Some consist chiefly of varicose veins with condensed cellular tissue; in some the mucous membrane is also hypertrophied, the hypertrophy of the membrane and its capillaries constituting the greater part of the tumour; while in others large arteries and veins are intermingled with the hypertrophied mucous membrane. The form of the tumours varies, some being sessile and bright red, others pendulous and livid, while in others there are but little traces of vascularity, the consistence being harder.

The following are the more frequent symptoms of P. There is first a feeling of heat, fulness, and a dull pain about the lower part of the bowel, with a sensation as if there were a foreign body in the anus. This gives rise to straining at stool, and a small tumour, usually about the size of a grape is protruded, which may remain outside or be retracted, according as it originated outside or inside the sphincter ani. Sometimes the tumour greatly increases in size, and may cause comparatively little annoyance; but, in the majority of cases, it becomes inflamed from stangulation of the sphincter muscle; it is exquisitely sensitive to the touch, and the seat of burning stinging pain rendering defecation difficult and excessively painful. In severe cases, the patient can neither sit nor stand, and every position is painful.

The treatment of *external* P. consists in the removal or palliation of their cause and the application of sedative and astringent agents. Habitual constipation must be relieved, and the bowels kept rather loose by some mild laxative such as the *confectio scamac sulphure* and the *confectio piperis nigri*. When the inflammation is mild, leeching is useful; but when severe, the tumour should be cut across with a lancet and the blood squeezed out. When old P. are much indurated, they should be stripped off, and along with them all loose folds of skin. The treatment of *internal* P. varies according to their extent, appearance, and form. When recent and small, the treatment is the same as for external P. The *unguentum gallæ co.* may be applied to the P. when protruded, or astringent injections after the bowels have acted; and when protruded they should always be returned by gentle pressure. In urgent cases, especially when the bleeding is considerable, the P. should be removed. Those of the sessile and capillary variety may be safely removed by the application of strong nitric acid to the whole of the surface; but when the tumours are large and pendulous, or hardened from inflammation, other means must be adopted. The chief plans of operating for P. are with the ligature, the clamp, and the cautery. In operating with the ligature, each pile is drawn out in succession with the forceps, and its base transfixed with a double silk ligature, or encircled in a ligature, the ligature being tied as tightly as possible and cut short. When all have been tied, the mass is returned into the bowel. In operating with the clamp and cautery, each pile having been drawn out, the clamp is applied to the base, and if the P. be small, the whole tissue may be seared down nearly to the level of the clamp; but it is generally necessary to cut off part of the pile, and sear the base of it till a thick eschar is formed. The galvanic is preferred by some surgeons to the actual cautery, as forming a thicker eschar. The operation by the clamp and cautery is the best mode, the recovery being more rapid, the operation being less painful, and there being less need of confinement to bed.

Pile'wort. See RANUNCULUS.

Pil'grim, a name meaning literally 'a traveller' (Ital. *pellegrino*, Lat. *peregrinus*), came to be reserved for those who made

a journey ("pilgrimage") to some place rendered sacred by association with the founder of their religion, or with some other holy person, being prompted either by veneration for the person in question or by the belief that they would thereby receive the pardon of sin. The practice of making pilgrimages is one that has prevailed in almost all countries and in connection with all religions, but perhaps most of all with Buddhism. After that religion was established as one of the three state religions of the Chinese Empire, pilgrims began to resort to India, which was the Holy Land of Buddhism. Many Buddhist pilgrims still visit annually Adam's Peak in Ceylon, and other places in India. The Hindus resort in thousands to the Ganges, the temple of Juggernaut in Orissa, &c. The different sects of the Japanese have all their regular places of resort, and, according to the Koran, a Mohammedan might as well die a Christian or a Jew as without making the pilgrimage to Mecca. The Holy Land of Christians is, of course, Palestine, almost every spot of which is hallowed by association with some incident in the life of Christ. Perhaps the first Christian pilgrim was Helena, the mother of Constantine, who in 327 visited Jerusalem and "discovered" the Holy Sepulchre and the Cross. Multitudes followed this illustrious example; and afterwards a pilgrimage to the Holy Land or the shrine of some saint became a common form of Penance (q. v.). In the Middle Ages these pilgrimages became the occasion of great abuses—idleness, begging, and debauchery—when Europe was swarming with men and women travelling in promiscuous companies. The ill-treatment received by the pilgrims from the Turks, after the latter conquered Palestine in the 11th c., led to the Crusades (q. v.), and when the country was finally abandoned by the Christians, pilgrimages to it were in a great measure stopped. This, however, only developed more fully pilgrimages to places in Europe—Loretto in Italy, St. Jago de Compostella in Spain, Canterbury in England, &c. The Reformation put a stop to the practice in the countries that adopted the new doctrines, and it seemed gradually dying out even in Catholic countries, in spite of the device of Jubilees (q. v.); but quite recently it has taken something like a fresh start, and thousands of Roman Catholics have been flocking to various places on the Continent where the Virgin Mary has been making her appearance.

Pilgrimage of Grace, the name assumed by the North Country insurgents of 1536, who, taking as their badge the Five Wounds of Christ, demanded the fall of Cromwell, union with Rome, redress to the Church, and the total reversal of the royal policy. Headed by Aske and other gentlemen, and 30,000 in number, "all tall men and well horsed," they marched upon York, chose Lord Dacre for their chief, with Lords Westmoreland and Latimer and nearly all the northern nobility as his subordinates, and within a few days had mastered all England N. of the Humber, with the single exception of Skippon Castle, commanded by the Earl of Cumberland. Under the imminence of the danger, Henry VIII. promised a free parliament at York; but scarcely had the insurgents returned home in triumph, when all concessions were revoked, and a renewal of the revolt (1537) was suppressed with ruthless rigour. The whole countryside was studded with gibbets, Lords Darcy and Hussey were sent to the block, the abbots of Fountains, Jervaulx, Barlings, and Kirkstead hanged, and Lady Bulmer burnt at the stake. See the Histories of Lingard, Froude, and Green.

Pillar, in architecture, a detached support, differs from a Column (q. v.) in not necessarily being of circular shape, and in not being regulated by the rules of classical proportion. During the successive periods of medieval architecture the P. assumed almost every variety of form. In the Norman style it is generally massive and plain, though sometimes fluted in a spiral or zigzag manner. In the Early English the P. becomes more complicated, and often consists of a group of smaller shafts, which correspond to the vaulting which they support; while in edifices of the Decorated Period this group of columns has an oblong or square instead of a circular arrangement. In the Perpendicular style the mouldings of the P. frequently run up into the arches, and occasionally the whole of the mouldings run up into the arches without any capital at all.

Pillar Saints (Lat. *Sancti Columnares*, Gr. *Stylitai*) were a peculiar class of monks who began to appear in the Christian Church in the 5th c. In the neighbourhood of Antioch, a monk

named Simeon (born at Sisan, in Syria, about 390 A.D.), whose excessive austerities had attracted admirers from all parts, had a pillar erected six cubits high, on which he took his stand, in order to escape the pressure of the crowd, and "in order to be nearer heaven." The better to accomplish this latter purpose he had the pillar heightened successively to twelve, twenty-two, thirty-six, and forty cubits. The top of it was three feet in diameter, with a balustrade round it. On this he stood constantly, eating only once a week, and engaged in prayer all night, and all day in giving counsel to the multitudes who resorted to him. In this manner he lived till his death, a period of thirty-seven years. Simeon found many imitators in the East, where the practice continued down to the 12th c., but in the West they were never allowed to carry out their purpose. See *Acta Sanctorum*, Asseman's *Acta Martyrorum Orient et Occident* (Rome, 1848).

Pillnitz, a village and modern royal château on the right bank of the Elbe, 7 miles S.E. of Dresden, and at the base of the Porsberg, which commands a splendid view of the surrounding country. The chapel and dining-room of the château are adorned with frescoes by Vogel. In a part of the château, since burned down, the P. Convention, an alliance between the Emperor Leopold II. and King Friedrich Wilhelm of Prussia, was framed, 27th August 1791.

Pillory (Fr. *pilorie*, Low Lat. *pilloricum*, from Class. Lat. *pila*, 'a pillar'), an obsolete instrument of punishment, in which the head and hands of the offender were secured through holes, in the same manner as the feet are held in the stocks. The P. was mounted on a scaffold, and the culprit was thus exposed to public opprobrium, which found vent in vocal abuse and showers of noisome missiles. The P. was used for many centuries in most European countries. In England it existed before the Conquest in the form of the *heafange* or *halsfang* ('catch-neck'). In *Piers the Plowman* (14th c.), a reference to the P. occurs—

'And yif ye lacche lyer, late hym nougth a capen
Er he be put on the pilorye.'—(Pass. ii. l. 202, 203.)

The P. was intended 'magis ad ludibrium et infamiam quam ad penam,' but serious injury and even loss of life has occurred where the mob was inflamed against the offender. On the other hand, when the victim was a favourite, or the prosecution unpopular, the punishment was transformed into a kind of triumph. The P. was exclusively the award of the 'forestallers, users of deceitful weights, perjury, forgery,' and such offences, till about 1637, when the press was hampered by restrictions, and all who printed books without a licence might be thus punishable. Henceforth those who suffered in the P. were chiefly authors and publishers of so-called libels and seditious pamphlets. Well-known cases are those of Leighton, Lilburn, and Warton the printers; Pymme, Bastwick, and Defoe. As late as 1814, the Earl of Dundonald (q. v.), for alleged stock-exchange swindling, was ordered to stand in the P., but the penalty was not enforced. The P. was finally abolished by the statute 1 Viet. c. 23, in 1837. The French *pillorie* or *canon* was abolished in 1832, and the *pranger* or *schandstuhl* of Germany has also been set aside by recent legislation.

Pills are the most convenient and portable form for the administration of most medicines, and this form is especially suitable for (1) all remedies which operate in small doses, as metallic salts; (2) those which are designed to act slowly and gradually, as certain alteratives; (3) those which are too readily soluble when exhibited in other forms; (4) substances whose operation it is desirable to retard until they have reached the lower intestines, as in certain P. for habitual costiveness; (5) bodies whose specific gravities are too inconsiderable to allow their suspension in aqueous vehicles; and (6) fetid substances; while it is unsuitable for (1) medicines which require to be given in large doses; (2) deliquescent salts; (3) fluid or semi-fluid substances, such as oils, balsams, &c., which require a very large proportion of some dry powder to render them sufficiently tenacious to form into a mass; (4) substances so insoluble, that when exhibited in solid form they pass through the intestinal canal unaltered, as extract of logwood (Paris's *Pharmacologia*). P. are formed from masses sufficiently firm in consistence to preserve the globular shape, and not so hard as to be of too difficult solution in the stomach and intestines. P. are rolled in flour, starch, magnesia, liquorice powder, and, on the Continent, in lycopodium. To prevent them from becoming dry and hard, as

well as to prevent their being tasted, P. may be enveloped in silver leaf, or coated with egg-albumen and ethereal solution of tolu. When P. are intended to pass through the stomach, so as to act entirely on the lower bowels, they are made up with alcohol, and varnished with an ethereal solution of tolu. The following are the P. contained in the British Pharmacopœia:—*P. aloes*, *P. aloes et assafœtida*, *P. aloes et ferri*, *P. aloes et myrrha*, *P. assafœtida composita*, *P. gambogia composita*, *P. colocynthidis composita*, *P. colocynthidis et hyoscyami*, *P. conii composita*, *P. ferri carbonatis*, *P. ferri iodidi*, *P. hydrargyri*, *P. hydrarg. subchloridi composita*, *P. ipecacuanha cum scilla*, *P. plumbi cum opio*, *P. quinia*, *P. rhei composita*, *P. saponis composita*, *P. scilla composita*. The ordinary weight of a pill is 5 grains, and the dose of all P. should be from 4 to 5 or 10 grains, unless otherwise directed.

Pilot (Fr. *pilote*, Dut. *piloot*, from Low Ger. *pilen*, 'to take soundings,' and Dut. *lood* or *loot*, 'lead'), a qualified sailor, specially licensed, in virtue of local knowledge, to direct the movements of ships passing through waters difficult of navigation, at a fixed rate of payment, which depends on the ship's draught of water, the distance, and the difficulty of the passage. As early as the 14th c. the laws of Wisby demanded that every shipmaster should employ a P. on nearing the coast. The laws regarding pilots and pilotage are consolidated in the Acts 16 and 17 Vict. c. 129, and 17 and 18 Vict. c. 104. It is provided that 'no master or owner of any ship is to be answerable to any person whatever for any damage done by the fault or incapacity of any qualified P. in charge of his ship within any district where the employment of such P. is compulsory.' The master of any vessel of more than 50 tons burden or 6 feet draught navigating the Thames is bound to employ the first P. that offers his services, provided he can produce his certificate and has hailed the vessel from a point near enough to admit of his call being heard by a proper lookout. The responsibility of a P. is limited to the amount of his bond. A P.-boat is distinguished by a large flag of red and white divided horizontally, and by the number of the P. to which it belongs marked on its bows and sails. A ship demanding a P. hoists a square blue flag. The chief guilds or 'brotherhoods' of English pilots are those of the 'Trinity Houses' of Deptford Stroud (whose jurisdiction extends from the Thames to the Isle of Wight), Kingston-upon-Hull, and Newcastle-on-Tyne. The general direction of P. guilds belongs to officials appointed by law as 'Pilotage authorities.' In the United States, pilotage is regulated by the Acts of Congress of 1789, 1837, and 1806, but the pecuniary liability of pilots is not quite settled. In the case of a collision, it has been decided by the Supreme Court that the owner of the ship to which the blame has been proved to belong is liable for damages even though a licensed pilot were on board at the time of the collision. Refusal to employ a licensed P. who makes a 'valid offer of service' vitiates the insurance on a vessel, and renders the master and owners responsible for the loss or damage of the cargo. In 1873, the pilots employed at Liverpool numbered 270; at New York, 176. The numbers of vessels piloted were 17,186 and 10,307 respectively.

Law Regarding Pilotage.—In the Thames and Medway, and along the coast from Orfordness to the Isle of Wight, pilotage is regulated by the Corporation of the Trinity House, and by the Lord Warden of the Cinque Ports. In other parts of the United Kingdom pilots are appointed and regulated by local Acts, or by ancient charters of incorporation, or by the Merchant Marine Act. In those parts of a voyage where a P. is employed by regulation or usage, termed 'a pilot's fair way,' one must be employed by an *oversea* vessel. Coasting vessels are not obliged to make use of them. The master of a vessel having a regular P. on board is not responsible for damage caused by the P. unless through unskillfulness or negligence. But his proceedings must not be controlled by the master, nor will the P.'s presence absolve the master from the consequences of his own carelessness. Authorities are empowered to give certificates to masters or mates who have passed an examination to conduct their own vessels. Where there is concurrent jurisdiction, a certificate must be got from each authority. The fees for pilotage are regulated by the distance and draught of the ship. 35 and 36 Vict. c. 72, empowers Trinity House to modify the rules as to pilotage rates.

Pilooty, Karl, Germany's greatest living painter, was born at Munich, October 1, 1826, and studied first under his father,

Ferdinand P., an eminent lithographer (died January 8, 1844), and afterwards in the Academy of Munich under Schorn. Shortly after his return from a journey to Paris, Brussels, and London, he was commissioned by the king to paint 'The Founding of the Catholic League' (1854), and the same which this picture gained him was greatly enhanced by his 'Send before the Corpse of Wallenstein' (1855). In 1856 P. became a professor in the Munich Academy, and its director in 1874. He has painted some fine portraits, but his masterpieces are the great historical pictures 'Nero on the Ruins of Rome' (1861), exhibited at the London International Exhibition of 1862, 'Galileo in Prison' (1864), 'The Death of Caesar' (1866), 'Thurselda in the Triumphal Procession of Germanicus' (1873), and 'The Arrest of Anne Boleyn' (1874).

Pilot-Fish (*Naucrates* or *Scomber dactylus*), a Teleostean fish belonging to the *Scomberidae* or mackerel family, and deriving its name from the supposition that it guided the shark towards prey. The fact seems to be that the P. follows the shark in the expectation of receiving a portion of the prey. Of old, the P.-F. was credited with directing sailors in the proper course. Its average length is 12 inches. One dorsal fin is developed, the great dorsal fin being represented by detached spines, not united by any fin membrane. The P.-F. resembles the Mackerel (q. v.) in form. Its colour is a silver-grey tinted with blue on the back, the body being encircled with five bands of a dark blue colour. The tail is 'keeled' or ridged above and below.

Pilpay. See BIDPAT.

Pilsen, a town of Austro-Hungaria in Bohemia, at the confluence of the Mies and Radbusa, 53 miles by rail W.S.W. of Prag, and 36 from the Bavarian frontier. It is well built and was formerly fortified. The chief buildings are the Church of St. Bartholomew and the Rathhaus, with a large collection of arms, but it has also a new theatre, 7 churches, and 2 monasteries. An important market is held annually. P. has great alum works and rich coal and iron mines, and produces excellent beer, linens, leather, and musical instruments. P. was stormed by Mansfield in 1618. It was the centre of the conspiracy of Wallenstein (q. v.), and in the market-place here twenty-four of his accomplices were executed in 1634.

Pimento, **All'spice**, or **Jamaica Pepper**, is a cheap and useful spice consisting of the dried unripe fruit of *Eugenia pimenta*, a handsome bushy tree native of the tropics of the western hemisphere, and much cultivated in some of the W. India Islands—particularly Jamaica. The berries are gathered when nearly ripe, their essential oil at that period being most abundant. They are then spread upon sheets on wooden platforms in the full exposure of the sun, and are frequently turned and winnowed until the drying is perfect. In this condition each is a brown rough berry of the size of a small pea crowned with the teeth of the calyx, and contains two dark-brown seeds embedded in a yellowish flesh. Odour and taste are aromatic and peculiar. It is from this peculiarity—a sort of composite flavour of cloves, cinnamon, and nutmeg—that the name allspice originated. P. is a good deal used in cookery and confectionery, and is sometimes given as a carminative to children. An oil distilled from it, known as oil of pimento, is an aromatic stimulant, but appears to be principally employed to communicate warmth and flavour to other drugs. See EUGENIA.

Pimpernel is a name that for some unknown reason has been given to plants of the genus *Anagallis*, belonging to the natural order *Primulaceæ*. It was originally applied to the burnet (*Poterium Sanguisorba*). *Anagallis* consists of about eight species of slender annual or perennial herbs found in Europe, temperate Asia, N. Africa, and S. America. They have axillary flowers, with a rotate or funnel-shaped corolla, succeeded by a many-seeded globose capsule bursting transversely, and are well represented by *A. arvensis*, the scarlet P., or 'poor man's weather-glass,' so called from its flowers closing before rain. It is a weed of wide distribution—common in England, less so in Scotland. The charming little bog P. (*A. tenella*) found creeping over the wet turf of marshy ground, is more particularly plentiful in W. Britain and Ireland. Italian P. (*A. monelli*) and a Barbary species called *A. collina* are with a series of varieties cultivated as ornamental garden plants. The name 'water P.' is given to *Samolus Patens*, another British

plant of the primrose order. It is, however, generally called 'brookweed,' while the 'yellow P.' is *Lysimachia nemorum*, a common copse and hedgebank plant also of the same order.

Pin. See PINS.

Pina Cloth is the name of a textile fabric manufactured in the Philippine Islands from the leaf-fibres of the pine-apple (*Ananassa sativa*). The process of extracting the fibre, dressing and dyeing it, involves much trouble, and as fine qualities only are used, the articles made of it are expensive—a small shawl or handkerchief costing one or two ounces of gold. *Pinilian*, which is the finest quality, exceeding the most delicate lawn in texture, is only woven to order—a piece for the ex-Queen of Spain, for instance, costing \$500.

Pinchbeck, a yellow alloy of copper and zinc, in the proportions of five to one respectively, formerly much used in the manufacture of cheap personal adornments. P. is named after its introducer.

Pind Dadun Khan, the most populous town in the district of Jhilm, Punjab, British India, 1 mile from the right bank of the river Jhilm, and 5 from the foot of the Salt Range. It was founded in 1623, and has manufactures of copper and brass ware, silk *lungis* or scarfs, carries on boat-building, and is the centre of the salt trade of the Punjab. It is an emporium for the distribution of commodities from England and Central Asia. The imports are valued at £130,000; the exports at £60,000. Pop. (1868) 16,740.

Pindar (Gr. *Pindaros*, Lat. *Pindarus*), generally called the 'Theban,' and by comparison the 'Lyrist,' is, by the verdict alike of ancients and moderns, the greatest lyric poet of Greece. He was born in the spring of Olympiad 64-63 (522 B.C.). The parentage of P. is very uncertain. Some say that he was the son of Daiphantos, others of Pagondas or Scopelinos, while his mother's name is variously given as Cleidice, Cleodice, or Myrto. All authorities, however, agree that his parents belonged to Cynoscephalæ, and that he was born at the place of that name between Thebes and Thepiæ. In P.'s family the art of playing the flute was hereditary. He was a kinsman of the Ægidæ and had Dorian blood in his veins. The beautiful myth that the poet in boyhood, on his road to Thepiæ, had been overcome by sleep, and that he awoke with bees clustering round his lips can hardly be passed over in any record, however brief, of the life of P. (For this and similar other myths see the Greek and Roman poets *passim*, but especially of Pausanias, ix. 23, sec. 2; Ælian, V. II. xii. 45; Horace, Od. iii. 4, 17-20.) The father of P., the greatest master of the musical art in his time, sent young P. to Athens for the completion of his education. Lasos of Hermione, the founder of the Athenian school of dithyrambic poetry, and other masters of the poetic art, are said to have been his instructors. Whether he contested the palm of poetry with the great Æolian poetesses Myrtilis and Corinna is of less moment than the fact that he had actually been their pupil. Corinna at first is said to have reproached P. with want of mythical knowledge in his earliest performances, and eventually to have said to him, when his genius was mature, 'Sow not from the full bag but from the hand.' The 10th Pythian Ode was written by him at twenty: the style is immature, the taste a shade below that of a few of the older lyrists, but the power is unquestionable. Once entered on the professional career of poet, P.'s services were in universal demand. At every festival in the Hellenic state he was indispensable. By Hiero of Syracuse, Alexander of Macedon, Theron of Agrigentum, Arcesilaus of Cyrene, and many of the rich and powerful in his own land his pen was not only even welcomed but eagerly solicited. Like Burns—the greatest of modern lyrists—while he was ever ready to lend himself to all that was lovely, pure, true, and generous, P. never swerved from the divine function of the poet. Gifts could not mar, nor could rewards emasculate his transcendent powers. Though most of his time was spent abroad at the courts of kings, P.'s genius was essentially patriotic and national. In 473 B.C. and for four years thereafter he was the guest of Hiero. He is supposed to have died in 442 B.C. P. wrote many poems—hymns, preans, dithyrambs, dirges, and *Encomia*. His triumphal odes—Olympian, Pythian, Ægean, and Isthmian—have a world-wide reputation. The poetical style of P. is peculiar. He abounds in wonderful conceptions and brilliant metaphors, but his *tournaire*

de phrase is so extremely abrupt that he is not only a difficult but even an obscure writer. Those, however, that have the patience to master his style find themselves well repaid by the delight which his vivid and vehement muse inspires.

Of his strength it hardly belongs here to speak; of his metres still less. Suffice it to say that P. belongs to the highest of the *Dii Majores* in Greek poetry. Any attempt to reproduce him in English has been unsuccessful. In no European language indeed does it seem likely that P. will ever be acceptably rendered. See *P.'s Leben und Dichtung* (Bonn, 1852); Villemain's *Essais sur le Génie de Pindare et sur la Poésie Lyrique* (Par. 1859). Cf. also the editions of Böckh (Leips. 2 vols. 1811-22); Donaldson (Lond. 1841); Dissen (2d ed. by Schneidewin, 1843); Cookesley (Lond. 1851); Hartung (1857); and Tychö Mommsen (1866); also Damm, *Lexicon Pindaricum* (Lond. 1814).

Pindaris, a collection of freebooters who established a system of terrorism in Central India at the beginning of the present century. They were mostly Mohammedans, but were bound together by no common nationality or discipline. They followed in the wake of the Mahratta armies, and were encouraged by the Mahratta leaders. In 1812 their numbers were estimated at 60,000 horsemen, armed with spear and matchlock. Their plunderings, torturings, and other excesses knew no bounds; and in 1817 Lord Hastings' resolution to restore order in Central India led to what is sometimes known as the fourth and last Mahratta War, in which the names of Elphinstone and Malcolm figure conspicuously. One of the Pindari chiefs, Ameer Khan, agreed to disband his followers in consideration of a *jageer* which has now become the State of Tonk (q. v.). Of the other three principal chiefs, one took poison, one surrendered himself, and the third was miserably destroyed by a tiger in the jungle. Their Mahratta allies, the Peishwa and Holkar, were completely defeated, and thirty hill fortresses were captured in a few weeks. The native states of Central India and Rajputana were formally taken under British protection; order was enforced among the Bheels and other wild tribes, and this part of India was placed in the direction of progress which it has since continued to pursue.

Pindus, a wild picturesque mountain range of ancient Greece between Thessaly and Epirus, forming the main watershed of the country. See GREECE and TURKEY.

Pine (*Pinus*) is one of the most important genera of the natural order *Conifera*, and has at times been variously united with the spruces, firs (properly so called), larches, and cedars, but is well distinguished from them by having persistent leaves in clusters of two to five in the axils of membranous scales, and the woody carpellary scales of its cones thickened at the apex. The leaves are evergreen, rigid, needle-shaped, varying from about an inch to more than a foot in length; the inflorescence is monœcious, the male catkins being in the axils of membranous bracts clustered round the branch in a dense raceme at the base of the current year's shoot; and the female flowers are solitary or in whorls on separate branches; the cones ripen in the second or sometimes in the third year; there are inverted ovules in pairs at the base of the imbricated scales, and three or more linear cotyledons. All are trees, many attaining a great height and size, and being of gregarious habit, they frequently form extensive forests. The genus consists of about 110 species, is confined to the northern hemisphere, abounding in the temperate and cold regions of Europe, Asia, and America—rarely occurring in the tropics, and not found on the mainland of Africa. The economic products are timber, tar, pitch, rosin, and turpentine; and the following is a selection of some of the most useful species:—*P. australis*—the long-leaved, southern, yellow, or Georgia pitch P.—along the S.E. coast of the United States clothes extensive dry sandy tracts known as the P. Barrens. The tree attains a height of 70 feet, furnishes a strong, durable, and much prized timber for house-builders and shipwrights; and yields the main supply of American turpentine, galipot, resin, pitch, and tar. It is distinguished by its long cylindrical cones, having the scales armed with recurved spines; the leaves are 10 to 15 inches long. *P. Canariensis*—Canary P.—forms large forests at about 5000 feet elevation in the Canary Isles, growing to a height of 70 feet, and furnishing a resinous, durable, very heavy wood, not readily attacked by insects. It is the only African species. *P. cembra* of the European Alps, Siberia, and Tartary,

grows to a height of 120 feet, and yields a good turpentine. The wood is of a yellow colour, very soft and resinous, of an extremely fine texture, and is extensively used for carving and cabinet-work. The seeds are edible, and yield under pressure a great quantity of oil. *P. Coulteri*, indigenous to the eastern slope of the Californian coast range at an elevation of 3000 to 4000 feet, is of rapid growth, attaining a height of about 100 feet, with a diameter of 4 feet, and produces the largest cones of all the pines. *P. Douglasii*—the Oregon P.—on some parts of the N. Pacific coast furnishes the principal timber of export, and is therefore of great commercial value in the lumber trade. The wood is very strong, fine, and clear-grained, splendid for masts and spars, also for flooring; has been known to attain a height of 400 feet and a stem diameter of 14 feet. *P. excelsa*—the Bhotan P.—occurs gregariously between 5000 and 12,500 feet elevation in the Himalayas, as also in Macedonia and Montenegro. It is a fine tree, attaining 100 to 150 feet in height, with abundance of turpentine, and gives a compact even-grained heart-wood, soft and easy to work, ranking in durability next to the Decodar. In India the bark is used to roof forest huts. An edible manna exudes from the leaves and branches. *P. Gerardiana*—the nut P. of Nepal—a middle-sized tree forming forests in the Himalayas, is principally valuable for its edible seeds, which are obtained by heating the cones, and are stored for winter use, forming in Kunnawar the staple food of the inhabitants. *P. Halappensis*—the Aleppo P.—a native of the Mediterranean region, forming irregular and open forests, and in its variety *P. maritima*, thriving on loose coast sands. It yields a kind of Venice turpentine as well as a valuable tar; the wood is esteemed for shipbuilding and furniture, and is useful for torches. The bark is employed for tanning. *P. Lambertiana*—the giant or sugar P.—native of the N.W. American coast region between lat. 40°-43°, is a lofty tree of rapid growth, attaining 300 feet, with a straight naked trunk of from 7 feet to 20 feet diameter. It thrives best in a sandy soil, and produces a soft, white, straight-grained wood, which for internal work (flooring, &c.) is esteemed above any other P. in California. The tree yields an abundance of remarkably pure and clear resin of a sweet taste, forming a substitute for sugar. The cones are 18 inches long, with edible seeds which are used for food by the natives. *P. Laricio*—the Corsican P.—a large tree forming extensive forests in Spain, Corsica, Asia Minor, &c., chiefly in mountainous districts where the soil is calcareous. It attains a height of 120 feet or more, furnishes a valuable, coarse-grained, elastic, and durable wood, is perhaps the most resinous of all pines, and on the French coasts has been extensively planted to stop the inroads of drifting sand. *P. longifolia*—the Emodi or Chir P.—is a large handsome tree of the Himalaya mountains, producing more turpentine and resin than any other conifer of that range. The wood as a rule is not durable, but is easy to work, and in hill districts is extensively used for building. *P. Mutsuwiana* is indigenous to China and Japan. It attains a height of 60 feet, and supplies a resinous, tough, and durable wood used for buildings and furniture. The roots when burned with the oil of *Brassica Orientalis* furnish the Chinese lampblack. *P. Munziesii* of N.W. America, is a very handsome tree, growing to a height of 70 feet, and furnishes a valuable timber. It thrives best in moist ground. *P. montani* (or *P. pumilus*)—the dwarf P.—occurs over large areas of the Alps and Carpathians, &c., luxuriating on the poorest soil. It yields freely an oil of turpentine used for medicinal purposes in Hungary, and exudes a resin. The wood serves for carving, firewood, and charcoal. *P. Pinaster*—cluster P.—occurring plentifully in the Mediterranean region, is marked by its clustered cones, and long thick rigid leaves, is of quick growth, and yields large quantities of the French turpentine. The timber is inferior. Having long spreading roots, it is peculiarly adapted for fixing loose shifting sands, more especially as it will flourish close to the sea, and has been largely planted for this purpose in France, converting enormous coast-wastes into valuable property. *P. Pinca*—the stone P.—also a quick-growing species in countries bordering the Mediterranean, forms a large tree, giving a whitish light resinous wood, much used for buildings, furniture, and ship-work. The cones take three years to ripen. The seeds are edible, and where the tree grows, are used as an article of food in the same way as almonds; they are made into sweetmeats. The taste is somewhat resinous, but not disagreeable. *P. ponderosa* of the mountains of N.W. America attains a height of more than 200 feet, and is of comparatively

quick growth. The heavy wood is in high estimation for general purposes. *P. radiata*, a Californian species, is a fine tree of rapid growth, attaining fully 100 feet high, with a straight trunk 2-4 feet in diameter. The wood is tough, and much sought for boat-building and manufacture of various utensils. It is a species that bears exposure at the very edge of the coast, and tar and pitch can be obtained from it. *P. resinosa*—red P.—indigenous to N. America, particularly Canada and Nova Scotia, furnishes a fine-grained red wood, heavy and durable, very resinous, and suitable for shipbuilding. It flourishes in dry sandy soils, attaining a height of 80 feet. *P. rigida*, or American pitch P., is a native of the northern United States, suits itself to rocky gravelly soils, sea-shores, or swampy ground, and the quality of its timber varies from heavy to light and soft, according to its place of growth. It is principally important for its large yield of resin and tar, but its wholesale destruction in the present century has much limited the supply. *P. Sabiana*—the Californian nut P.—is most frequent on the western slopes of the Rocky Mountains. It produces a large, pale, and soft timber. The cones attain a foot in length, and the seeds are edible. *P. Strobus*—in England called Weymouth P., in America the White P.—a large and important tree, reaching to 250 feet in height and a girth of 18 feet, is a native of the northern United States and S. Canada. The wood is light coloured, soft, but with little strength. It is freely used in N. America for building, furniture, and other purposes, and is a source of supply of turpentine and gallipot. It was introduced into England in 1705, and is now grown on a considerable scale in Germany. The *P. sylvestris*, called Scotch fir, is a native of N. and mid Europe (up to 70° N. lat.), also of N. Asia. It is a very valuable tree, eminently gregarious in its habit, forming extensive natural forests, and thrives best in sandy soil, as it requires free drainage, attaining, under very favourable circumstances, a height of 150 feet. The sap-wood is large, enclosing a distinctly marked reddish heart-wood, which is durable and strong. The red deals from the Baltic and Norway are of this species, as well as a large portion of the European tar. It is frequent in peat-mosses, showing that it was formerly a native of England and Ireland. *F. Tada*—the flankingine or loblolly P.—grows in the marshes that intersect the 'pine barrens' of the southern United States, preferring a position near the coast. It yields turpentine of good quantity, though of inferior quality. The timber is not of much value. In Mexican pines we have *P. Tecote*, which gives a large resinous timber of durable quality; and a Japanese species, *P. Truga*, the wood of which is small, but is highly esteemed for superior furniture.

Pinus Pinus.

The emanations from P., particularly the very resinous species, are antimalarian and antiseptic, as proved by residences near P. forests, and by the use of hospitals constructed of P. wood. Other important trees, mostly belonging to the genera *Abies* and *Cedrus*, that have in the varying botanical nomenclature borne the name of Pinus, and are still sometimes spoken of as P., are purposely excluded from the above selection. For some of such see FIR and CEDAR. Species of *Araucaria* (q. v.) are termed Chili P. and Norfolk Island P., &c., and the *Dammara australis* has the name of Kauri P. (q. v.). These are all *Conifera*, but the plants called Screw P. belong to *Pandanus* (q. v.).

Pinéal Body, or Gland, or Conarium. A small conical body of reddish-grey colour, situated behind the posterior commissure of the brain. It attains a length of about an inch, and a breadth of 2 or 3 inches at its base. It is larger in youth than in age, and in females than in males. The P. B. is connected with the *cerebrum* at its base by *long peduncles* or stalks,

and by some few cross fibres as well. It consists chiefly of grey matter, and is well supplied with blood-vessels. A small cavity exists at its base, and within this cavity a viscid fluid, containing calcareous or limy particles, is found. The functions of the P. B. are unknown.

Pine-Apple belongs to a genus of tropical *Bromeliaceæ* (q. v.), having rigid leaves pointed and edged with sharp spines, and a fruit that is technically called a sorosis—that is, composed of numerous ovaries, floral envelopes, and bracts, all combined so as to form a succulent mass. It is named botanically *Ananassa sativa*, and is believed to be a native of Brazil, whence it has passed to other parts of tropical America, including the W. Indies, and more lately to parts of Asia and Africa. It became known to Europeans about the middle of the 16th c. We hear of it in England a hundred years later, some having been sent as a present to Cromwell; and Evelyn in his *Diary*, under date August 9, 1661, tells of its appearance at a banquet given by Charles II. at which he was present. In 1718 the cultivation of the P.-A. was first successfully established in England in the garden of Sir M. Decker, in Richmond, Surrey, in pits heated with bark, the plants being watered with tepid water. The first formal treatise on its culture was published in 1769. The author (Giles) gives a plan of a pinery heated with tan and flues. Many works have since been written on the subject, including all the minutiae of selection of soils, descriptions of houses and pits, mode of heating, times and manner of potting, watering, manures, shading, temperature, propagation, selection of varieties, expedients for enlarging the size and improving the flavour of the fruit, diseases, malformations, &c.; and the successful growth of the P.-A. is considered a test of the gardener's ability in large establishments. The fruit should be bright and golden in colour, heavy in proportion to bulk, surmounted by a small sturdy cone of leaves, the scent strong, the juice rich, of the consistence of honey, and of an exquisite flavour. These qualities combined render it the king of dessert fruits. It also makes an admirable sweet preserved in sugar or made into jam. In Devonshire pine-apples of 5 lb. weight have been grown and ripened in the open air. The fruit now hawked about the streets of London and elsewhere is imported from the Bahamas, and is a poor variety. The name P.-A. is taken from the general resemblance of the fruit to a large cone of a pine-tree.

Pine Chafer (*Hylophagus piniperda*), a species of beetle, belonging to the *Hylophagidæ* or Bark Beetles (q. v.), and infesting Scotch firs. It feeds on the young shoots of these trees, and appears to eat its way to the stem. It is of small size, and of blackish-brown colour.

Pine Finch, or **Pine Grosbeak** (*Pinicola or Pyrrhula eunclator*), a species of *Insectorial* birds belonging to the section *Corviæstræ*. P. F. is one of the Bullfinches (q. v.), and attains a length varying from 7 to 9 inches. The head, neck, and throat are red, the back blackish-brown, and the under parts light grey. The wings and tail are of a dusky brown, variegated with white markings. The P. F. occurs in the Arctic and northern regions of both hemispheres; but in the western it migrates southwards to the United States in winter. It lays four or five eggs of a pale-green hue spotted with brown. The bird is chiefly found near pine forests, and feeds on the seeds and shoots of these trees as well as on those of the birch willow.

Pinel, Philippe, a French physician, celebrated for his treatment of lunacy, was born at Saint-André (Tarn), April 20, 1745. After studying at Toulouse and Montpellier, he removed to Paris in 1778. Here he devoted his attention to the study of lunacy, and became directing physician to the asylum at Bicêtre in 1791, and at Salpêtrière in 1795. In the latter institution, which admitted female lunatics only, he commenced a class of clinical surgery, which he continued along with his pathological lectures in the School of Medicine in Paris. His great fame rests upon his treatment of lunatics, which was a complete revolution of the old barbarous methods. Naturally his system roused vigorous opposition at the time; but in a few years it was generally accepted over the whole of Europe. P. died at Paris, October 26, 1826. His chief works are *Traité médico-philosophique de l'Aliénation Mentale* (1791), *La Nosographie Philosophique* (1798, 6th ed. 1818), a work which marks an epoch in the history of the French medical school, and *La Médecine Clinique* (1802), besides numerous papers in the *Jour-*

nal de Physique and the *Journal de Fourcroy*. He also edited for a lengthened period *La Gazette de Santé*. See Cuvier's *Eloge de P.* (*Mémoires de l'Académie des Sciences*, vol. ix.).

Pinerolo, or **Pignarol**, a town of N. Italy, province of Turin, on the river Lemnana, at the entrance to the valley of Perosa, 1200 feet above the sea, and 23½ miles S.W. of Turin by rail. It is (since 1848) a bishop's see, and has a fine modern cathedral, 14 churches, and 2 seminaries. P. manufactures silks, woollens, cottons, and paper, and has considerable trade in wine and Alpine cheese. The fortress of P., for a time the prison of the 'Man with the Iron Mask' (q. v.), was from the 11th c. to its destruction in 1696 alternately in the hands of the house of Savoy and of France. Pop. (1874) 16,800.

Piney Tree. See CALOPHYLLUM.

Piney Varnish. See DAMMAR.

Pinguic'ula. See BUTTERWORT.

Pink is the name of a well-known shade of light red; but several substances known as pinks are shades of yellow rather than red. Dutch P., for example, is a greenish-yellow colour, prepared by impregnating a white earth with decoctions of yellow berries and turmeric.

Pink (*Dianthus*) is a genus of *Caryophyllaceæ*, consisting of about seventy species of tufted herbs with narrow grass-like leaves, solitary flowers arranged in panicles or fascicles, tubular five-toothed calyx, five long-clawed petals with entire or cut limb, ten stamens, two styles, and a capsular fruit. It is represented through Europe, temperate Asia, N.W. America, and N. and S. Africa. The garden P. (of which by specialists some 300 varieties are enumerated) originates from *D. plumarius*, a plant of mid-Europe occurring also much in its wild form on old ruins in several places in England. From *D. caryophyllus* the numerous varieties of the Carnation (q. v.) are derived. Both of these are justly favourite garden flowers, and are propagated by pipings and layers. *D. barbatus*, another European species, with flowers in dense fascicles at the top of the stem, is likewise often seen in gardens under the name of 'Sweet William.' *D. superbus* ('Sweet Johns' of old), a striking and sweet-scented European species, is also cultivated. The native British plants of the genus are the 'Deptford P.' (a name given it by Gerard in 1597 from his finding it there); *D. Armeria*, which is a rather rare species; *D. deltoides*, the 'Maiden P.', a much branched perennial, with pretty mottled rose-coloured flowers, found in dry-soil ground both in England and Scotland; *D. casius*, confined to the limestone cliffs of Cheddar, and called the 'Cheddar P.' in consequence; and *D. profler*, a rare S. of England species. None of the genus has any established medicinal qualities. For the plant called 'Sea P.' see THRIFT.

Pink'erton, John, a Scottish antiquary and historian, was born at Edinburgh, February 17, 1758. After six years' schooling at Lanark, he was apprenticed for five years to an Edinburgh writer to the signet, and published an *Ode to Craigmillar Castle* (1776). In 1780 he came to London, where he gained the friendship of Horace Walpole, and through him of Gibbon, by his *Essay on Medals* (1784) and *Letters on Literature* (1785), the latter affecting a singular orthography intended 'to reduce the harshness of the English tongue.' The *Ancient Scottish Poems never before in Print, from the MS. Collection of Sir Richard Mackand* (2 vols. 1786) have been unjustly branded as a literary forgery, though in the preface P. acknowledged his earlier *Rimes* (1781) and *Scottish Tragic Ballads* (1783) to have been mainly of his own composing. In the *Dissertation on the Origin and Progress of the Scythians or Goths* (1787), and *Inquiry into the History of Scotland preceding the Reign of Malcolm III.* (2 vols. 1790), 'snarling' P., as Burton styles him, 'railed at the plaid, and blasphemed the claymore,' everything Celtic coming in for a storm of indiscriminating abuse, and the modern Highlanders being described as 'mere savages, but one degree above brutes, indolent, slavish, strangers to industry,' whose breed requires to be utterly exterminated. Other works by P. were his *Medallist History of England to the Revolution* (1790); *Iconographic Scotiæ* (2 vols. 1795-97); *History of Scotland from the Accession of the House of Stuart to that of Mary* (2 vols. 1797); *Walpoleana* (2 vols. 1804); *Modern Geography* (3 vols. 1802-7); *Collection of Voyages and Travels* (16 vols. 1808-13), &c. P. settled in Paris (1802), and died

there, poor and forgotten, March 10, 1826. See his *Literary Correspondence* (2 vols. Lond. 1830).

Pink Root. See SPIGELIA.

Pinn'a, a well-known genus of *Lamellibranchiate Mollusca*, familiarly known as the Mediterranean Mussel. It belongs to the family *Aniculidae*. The shell is wedge-shaped and of horny texture. No hinge exists. This mollusc, like the common mussel, secretes a *byssus* or 'beard,' and is notable for the large amount of silky material it can thus produce. So abundant is the 'beard' of the P. that the Sicilians and Maltese weave stockings, gloves, &c., from it. Pope Benedict XV. was presented with a pair of stockings in 1754 made from it. Many species belong to this genus. *P. pectinata* occurs in British seas; *P. nobilis* is a well-known Mediterranean genus, and *P. nigrina* and *P. rudis* are also familiar species.

Pinn'ace (Sp. *pinaza*, Fr. *pinasse*, from Lat. *pinus*, a 'fir tree,' the wood of which was originally used in the construction), a large eight-oared boat, next in size to the launch, carried by men-of-war; also a light schooner-rigged vessel provided with oars.

Pinn'acle (Low Lat. *pinnaeculum*, from *pinna*, 'a feather,' hence what is pointed like a pin or feather), in architecture, a small turret of a square or polygonal shape, used as a terminal ornament to buttresses, the tops of gables, &c. It is most frequently met with in edifices of the Late Gothic period. Decorated pinnacles have frequently niches in their faces, each of the sides terminating in a pediment, and the tops being generally crocketed, with finials on the points.

Pinnigra'da and **Pinnipe'dia**, terms applied to that section of *Carnivorous* quadrupeds, including the Seal (q. v.) and Walrus (q. v.), in which the limbs are modified to form swimming paddles. In these animals the body is long and fishlike. The tail is short and rudimentary, and the limbs are also short. The hinder legs are placed far back on the body, so that their axis nearly corresponds to that of the body itself, and the hind limbs together with the posterior extremity of the body form an admirable swimming apparatus. The toes are provided with strong nails. External ears may be wanting, and at most are rudimentary. Both ears and nostrils are valvular, and may be closed at will. The bones are of spongy texture and light construction. The canine teeth are long and pointed.

Pinnotheres. See PEA CRAB.

Pinnular'ia, a genus of peculiar plant fossils found in rocks of Devonian age. They consist of slender smooth-surfaced bodies, which give off at right angles long and delicate branchlets. By Dawson, P. is considered to represent the roots of other plant fossils, just as the *Stigmara* of the coal, formerly regarded as a distinct plant, was found to be the root of *Sigillaria*.

Pinn'ule. The leaflets that compose a pinnate leaf are called pinnule. If these again are subdivided in a pinnate manner, the leaf is termed bipinnate, and the secondary pinnule are called pinnules. See LEAVES.

Pins (Lat. *pinna* or *fenna*, 'feathers;,' what are pointed like such). The manufacture of P. is one of the characteristic industrial features of Birmingham, where, so far as regards Great Britain, they are chiefly made. Although what are termed 'solid-headed' P. are now only seen, the period is within the recollection of comparatively young people, when the head of a pin consisted of a separate piece of thin wire, twisted around and fastened to the body or shank. Previous to the introduction of the solid-headed pin, the making of a pin involved numerous separate operations, which were mostly performed by manual labour; but now P. are made by self-acting machinery. To a pin-making machine wire of suitable gauge is supplied from a coil wound around a drum, the machine itself, moved by steam power, drawing in its supply of wire at the rate it needs the raw material. As the wire enters the machine it is straightened by being pulled through a series of upright pegs, after passing which the end of the wire is caught between a pair of lateral jaws and held for an instant, during which time it receives a succession of smart blows from a sliding bar or hammer, whereby the head is formed. At the same instant a knife descends, and cuts off the proper length of wire for a single pin, and the article, so far formed, falls into a slit or groove, the opening of which is too small to allow the head to pass through. In this groove the P. consequently

arrange themselves with the ends to be pointed turned downwards, and the groove itself forms a long inclined plane, under which a revolving file is in motion. The file presses against the points of the P., and being arranged in an inclined plane, these move onwards with a kind of revolving motion, thus presenting every side in turn to the action of the file, and therefore before the P. finally fall out of the groove, they have received fine properly tapered points. At this stage the P. are perfect so far as regards form; but they present a dirty, brassy yellow appearance, very different from the proverbial clean aspect of a new pin. Most commonly, P. are finished by the process of whitening or so-called silvering. For this purpose the P. are first cleaned by agitation in revolving barrels in which they are mixed with fuller's earth and water. From this they are transferred to a steam-jacketed copper pan, in which they are boiled with granulated tin, to which a certain proportion of cream of tartar (potassic bitartrate) is added. When the P. are removed from the copper boiler they are found to be coated with a thin film of tin, to which their fine silvery appearance is due. It is only necessary now to dry the P., an operation accomplished by agitating them in barrels with dry bran, and they are finally freed from that substance by subsequent winnowing. A very interesting process now remains to be performed with the finished P., that is the papering. It is done by a machine to which a hopper is attached, and into it a large quantity of P. are thrown. By a constant raking agitation, the attendant manages to get rows of P. with points downwards through grooves at the lower part of the hopper. A single row is advanced from the hopper at a time, and the points of that row come in contact with the paper folded and crimped ready to receive them. By a treadle action the whole row is forced into the prepared paper at one stroke; the paper moves forward and another row of P. is liberated for papering in the same manner. A large proportion of the P. now used are simply weighed and put up in small boxes, and in these operations the females employed display remarkable dexterity. P. are in some cases finished by japanning, and sometimes, especially those for etymological use, are gilt.

A patent for making solid-headed P. was secured in 1817 by Seth Hunt; but the first machine that was successfully worked was that patented by Lemuel W. Wright, an American, in 1824. A five years' extension of Wright's patent was granted in 1837. Since that date many improvements have been made on the apparatus, and it is now one of the most perfect pieces of automatic machinery in operation. The daily production of P. in the United Kingdom is calculated to be 50,000,000, of which Birmingham produces nearly three-fourths, London, Stroud, and Dublin sharing the residual fourth between them. The weight of wire, including a fractional amount of iron wire used in the manufacture of hair and mourning P., consumed annually in England for this enormous production is about 1276 tons.

Pinsk, a town of W. Russia, government of Minsk, on the river Pina, which flows into the Pripiet, an affluent of the Don, 210 miles from Warsaw, and 118 from the Austrian frontier. It is situated in an extensive swampy plain 440 feet above the sea, and, connected by the Oginsky Canal with the Niemen, is the centre of a considerable transit trade, chiefly in corn, tallow, wool, timber, tar, and glass, and has manufactures of Russia leather. Pop. 17,718. P., founded in the 12th c., and annexed to Poland in 1569, became Russian in 1795.

Pint (Fr. *pinte*, Sp. *pinta*) is a measure of capacity equivalent to one-half of a quart and one-eighth of a gallon. It is for the most part limited to liquids. The old Scotch pint was equal to about three imperial pints.

Pinta'do. See GUINEA FOWL.

Pin'tail Duck (*Dafila acuta*), a species of *Anas* or ducks in which the hinder toe is small, and not united by the web to the other toes. The bill is narrow, and has no tubercle at its base. The body and tail are long, the latter tapering in the male, hence the familiar name of the species. The P. D. occurs in the northern hemisphere, is found in Britain in winter, and also inhabits the Gulf of Mexico, the W. Indies, and the Mediterranean Sea at that season. Its colour is brown, varied with black and white lines above, and white below. The flesh is very palatable. The bird breeds in captivity, and may be readily domesticated.

Piombino, a former principality of N. Italy, stretching along the coast opposite the island of Elba, from which it is separated by a channel of the same name. Its area before its absorption by Tuscany was 132 sq. miles, and its pop. 25,000. Originally part of the territory of Pisa, it became a principality of the Apiani family in 1599, but was subsequently acquired by Spain, and later by the Buoncompagni-Ludovisi family, from whom it was wrested by Napoleon in 1805. Napoleon conferred it on Felix Baciocchi, his brother-in-law, who was ejected in favour of the old dynasty in 1816. It was finally annexed to Tuscany, and became part of the kingdom of Italy in 1859.—**P.**, formerly capital of the principality, is situated at the southern extremity of a woody promontory opposite Elba, and has a good harbour and old fortifications. The roadstead, Porto Vecchio, is safe and commodious. There is a large Bessemer steel work here, supplied with ore from Elba. Admirable military projectiles, of great hardness, are also manufactured. Pop. (1874) 2755.

Pioneers (Fr. *pionniers*, from Old Fr. *peon* = Ital. *pedone*, 'a foot-soldier'), labourers or artisans attached as soldiers to the infantry regiments in the British army. Their duties are the removing of obstacles on the line of march, the digging of trenches, making of bridges, sinking of mines, and generally the direction of all fieldworks. Thirteen picked men march as P. at the head of every regiment, armed with saw-back swords, and carrying among them the picks, shovels, axes, saws, crow-bars, and working implements of the regiment slung over their shoulders. Unlike the rank and file, they wear beards.

Piotrków, or **Petrokov**, the capital of a government of the same name in Russian Poland, on the Stradra, 65 miles S.W. of Warsaw by rail. One of the oldest of Polish towns, it has a beautiful town-house, a ruined castle, many interesting churches and monastic buildings, but retains little of its former prosperity. P. was the place where the Polish Diet met and the kings were elected during the 15th and 16th centuries. It was burned by the Swedes in 1702, and the Russians gained a victory here in 1709. Pop. (1870) 13,633, of whom a great number are Jews.—The government, formed out of Warsaw in 1867, is the most industrial part of Poland. Along the Lodz are grouped the chief weaving and spinning works, and within P. there are 82 cotton-mills, 17 wool-spinning factories, 66 great woollen-cloth mills, 10 machine works, &c., employing about 30,000 workmen, and producing goods to the value of 3½ millions sterling. Area, 4729 sq. miles; pop. (1872) 682,495.

Piozzi, Hester Lynch, born in January 1741 at Bodville in Caernarvonshire, was the only child of John Salusbury, Esq. of Bachygraig, Flintshire. In 1763 she married Mr. Henry Thrale, a wealthy brewer and M.P. for Southwark, and her sprightly wit soon gathered round her a brilliant circle, including Reynolds, Burke, Goldsmith, Garrick, the Burneys, and, most famous of all, Dr. Samuel Johnson. In the Thrales' townhouse and Streatham villa the lexicographer for sixteen years found, says Boswell, 'all the comforts and even luxuries of life, his melancholy was diverted, and his irregular habits lessened by association with an agreeable and well-ordered family.' Her husband dying in 1781, Mrs. Thrale settled with her four daughters at Bath, where in 1784 she married an Italian music-master, Gabriele P., to the great disgust of Johnson, and indeed of all her friends. At Florence, where she formed an acquaintance with the founders of the Della Cruscan School, she lost her second husband (1809), and returning to England, died at Clifton, May 2, 1822. Besides her *Anecdotes* (1786) and *Letters* (1788) of Dr. Johnson, she published a vast number of long-forgotten works. See A. Hayward's *Autobiography, Letters, and Literary Remains of Mrs. P.* (1861), and R. O. Mason's *Mrs. Thrale, the Friend of Dr. Johnson*, in *Macmillan's Magazine* (1876).

Pipa or Surinam Toads, a genus of *Amphibia* belonging to the Frog order (*Anura*), but to a distinct family (*Pipidae*). In this group the head is broad and triangular, and the snout somewhat pointed and prominent. No teeth exist in the genus P., and the tongue is absent. The eyes are placed close to the mouth, and the legs are extremely powerful, the toes of the hind feet being completely webbed. The best known species is the Surinam toad (*Pipa americana*). An allied species (*Dactylethra*) occurs at the Cape of Good Hope. In P. a most curious habit marks the female. In the back are excavated a number of shallow

low pits or cells, and the eggs on being deposited by the female are placed by the male in these cells. The young undergo their metamorphosis within the cells in the mother's back, and emerge therefrom as the perfect animals in about eighty-two days. The P. is about 7 inches in length. Its skin is warty, and of a brownish-olive tint.

Pipe, a wine and oil measure of capacity, the value of which varies not only with the country or locality, but also with the kind of wine. Thus a P. of port contains 114 imperial gallons; a P. of sherry, 108; and a P. of Madeira, 92. The ordinary English P. or butt is equivalent to 105 imperial gallons.

Pipeclay, a variety of fine plastic clay used, on account of its freedom from colouring impurities, in the manufacture of tobacco-pipes and fine pottery. It is procured in considerable quantities in Devonshire, Dorsetshire, and Cornwall, in England.

Pipe-Fish (*Syngnathus*), a genus of Teleostean fishes belonging to the sub-order *Lophobranchii* (q. v.), and nearly allied to the *Hippocampus* or Sea-horse (q. v.). They have long slender bodies, and derive their popular name from the resemblance of the jaws to a pipe. The dorsal fin is single and is set far back in the body, and the anal fin is small or may be wanting altogether. As in the sea-horses, the males have a pouch near the anus in which the young are hatched, and afterwards protected for a considerable period. The gill aperture is small and circular. Of the P.-F. the *S. acus* or Great P.-F. is a good example. It occurs on the British coasts, and attains a length of 15 or 18 inches, but larger specimens are not uncommon. Its colour is a pale brown, diversified with dark cross bars. The snake P.-F. (*S. anguineus*) attains a length of 14 inches. Its body is more slender than in the preceding species, and it has the dorsal fin placed forward on the body. The food consists of small crustaceans and other animals.

Another group of fishes named P.-F. is the family *Fistulariidae*, of which the *F. tabaccaria*, or tobacco P.-F., is a good example. They also have a long snout, and are in some respects allied to the Mulletts, &c.

Piperaceæ, or the Pepper (q. v.) family, is a natural order of dicotyledonous, erect, or climbing shrubs or herbs, with articulated stems, simple leaves often of a fleshy texture, small flowers without perianth, arranged in a spiked or racemose manner, and fruit small, berry-like, and one-seeded. The number of species is about 600, found in the hottest countries of both hemispheres. Many are natives of America; those with succulent leaves growing in dry, rocky ground, whilst others are epiphytes. *Piper* is the principal genus. Some of the *Peperomia* are cultivated as objects of curiosity in stove-houses. *Artanthe* furnishes the Matico (q. v.) of the Peruvians. The properties of the order are pungent, acrid, and aromatic; some are narcotic and astringent.

Piperine ($C_{17}H_{19}NO_3$), a colourless, sometimes yellowish, crystallisable alkaloid, extracted from pepper by boiling with alcohol. It is insoluble in water, but readily dissolves in alcohol and ether.

Pipes, or **Tubes**, used for the conveyance of gas or water, and for numerous other purposes, are, in a social and sanitary point of view, as well as in engineering relations, of great importance, and the industries connected with their manufacture are extensive and varied. Being used for a great variety of purposes, they are fabricated of many materials, such as india-rubber, leather, earthenware, lead, brass, copper, cast iron, and malleable iron, and other metals. They are also in consequence manufactured in many different ways, and they moreover vary in size from P. of a very minute bore up to castings of 4 feet in diameter. Here attention will only be directed to the distinctive features of the manufacture of P. and T. for gas and water supply. The 'mains' or leading P. for both gas and water are made of iron, cast iron being most commonly adopted, but in the case of gas malleable iron P. are also much employed. For internal circulation of gas and water, lead P. are generally employed. These three varieties will be briefly described. *Cast iron P.* are made with great accuracy and despatch by means of the pipe-moulding machine introduced and patented in 1846 by Mr. D. Y. Stewart, of Glasgow. The essence of Mr. Stewart's invention consists in having the P. cast in a vertical or upright position, whereby a much more solid, uniform, and equal casting is secured than by making a horizontal casting, in which inevitably the

under part of the pipe would be thicker, more solid, and stronger than the upper part. At the same time the mould and curve are made much quicker and with greater nicety in Mr. Stewart's apparatus than was possible in the earlier process of pipe-casting. In casting P. the sockets are usually cast 'down' or at the lower part of the moulding machine, whereby a sound solid socket is secured. From the upper part of the pipe, a piece of about 8 or 9 inches is cut after casting, and thus a sound pipe is secured. Ordinary P. are cast in 12-foot lengths; but those of large diameter, such as the Glasgow 4-foot supply pipe, are only 9 feet long. *Malleable iron P.* are of two main classes, butt-welded and lap-welded, according to the manner in which their joints are closed. The iron for malleable P. is received in the form of plates of the required length and thickness. It is cut into strips of a breadth sufficient for the diameter of the tube to be made, and these strips are known as 'skelps.' These skelps are heated to a welding heat; one end is beaten into a semicircular form, and the whole strip is then drawn through between a pair of rolls, the opening between which is a circle corresponding to the external diameter of the tube to be made. Thus the edges of the skelp are forced together, and a joint sufficient to resist a moderate internal pressure is formed. In lap-welded P. the skelps have bevelled edges, and are first drawn into an oval form, one edge overlapping the other. The tube is reheated, a mandril is inserted, and the weld completed by hammering; after which the circular form is given to the tube by passing it between circular rolls. Such pipes are used for steam boilers, and in other positions where they are subject to great pressure. *Lead P.*, such as used by plumbers and gasfitters, are made in continuous lengths by a peculiar process. The metal is melted, and in the molten condition it is forced by hydraulic pressure through an annular aperture. This aperture represents the diameter and the thickness of the pipe to be made. The metal is brought to that condition in which, while it is possible to force it through the aperture, immediately it emerges it is sufficiently solidified to retain the tubular shape it assumes by being forced through the opening. Consequently a continuous stream of finished tube is forced upwards by the apparatus, the length of the pipe made being only limited by the quantity of metal operated on and the weight of the pipe formed. P. of 7 or 8 inches gauge are thus made, but the greater proportion of lead P. are of much smaller dimensions.

Pipe-Sticks. See TOBACCO-PIPES.

Pip'i is the astringent pod of *Cresaltina Pipai*, sometimes though rarely exported from the W. India Islands for tanning purposes. When (as more frequently happens) it comes intermixed with Divi-divi (q. v.) it detracts from the market value of the import. P. is a straight pod, whilst that of divi-divi is curved like the letter S.

Pip'it, the name of several *Inessorial* birds belonging to the *Dentirostral* section of the order, and allied to the Wagtails (q. v.) or *Motacillinae*. Of the pipits the best known are the Meadow P. (*Anthus pratensis*) and the Tree P. (*A. arboreus*). The Rock P. (*A. aquaticus*) and Richard's P. (*A. Richardi*) are also well-known species. The Meadow P. or Meadow Titling is a British bird, attaining a length of 6 inches. It is of a dark-brown colour tinted with olive. The wing is dark-brown, the under part brownish white. This bird is termed the 'Mosscheeper' in England, and the 'Wekcen' in Ireland. The latter name is derived from its note. It occurs in the N. of Europe, and has been found in India and Japan. The eggs number from four to six, and are of a reddish brown colour. The Tree P. arrives in Britain in April, and leaves in September—this bird, unlike the preceding species, being migratory. It is larger than the Meadow P., but closely resembles it in colour. Its hinder claws are small.

Pippi. See GIULIO ROMANO.

Pippin is a name that has long been current for certain varieties of apples, and is generally supposed to have been originally applied to superior forms raised direct from pips or seeds. It is, however, recently suggested that it may have had reference to the white dots on the fruit. Ribston P., Golden P., and Newtown P., are familiar examples.

Pippin (Fr. *Pépin*), the name of a celebrated family which played an important part in the history of the Frankish Empire,

and to which belonged the Karoling princes. **P. of Landen** (near Liège) was mayor of the palace (major domus) in Austrasia under King Dagobert I. (628-638). After the death of Theodoric II., P. and Arnulf, Bishop of Metz, representing the lay and spiritual aristocracies respectively, were put forward by the leudes to counteract the ambitious designs of Brunhild. After her fall their friendship was cemented by the marriage of Arnulf's son Ansegisel to P.'s daughter Begga. P. died in 639, and was succeeded by his son Grimold, who was mayor of the palace to King Sigebert of Austrasia. On Sigebert's death (656) Grimold, after banishing Sigebert's son to an Irish monastery, attempted to set his own son upon the throne, but in a rising of the leudes both he and his son were taken and sent to Hlodowig II., King of Neustria, by whom they were put to death. Yet the P. family continued rich and powerful. **P. of Herstal** (on the Maas, between Maastricht and Liège), son of Ansegisel and Begga, and his cousin Martin were in 678 chosen Austrasian mayors of the palace, and leaders of the Austrasian people against Ebroin, major domus of Neustria and Burgundy. After the murder of Martin by Ebroin, P.'s power was the less restricted, especially as the throne of Austrasia had stood unoccupied from 678. He was now not merely mayor of the palace, but 'Duke of the Franks' (*Dux Francorum*). Ebroin died in 681, and P. was repeatedly called to take part in the struggles of parties in Neustria. At length, in 687, he gained a decisive victory at Testry, in the Vermandois, over Berthar, mayor of the palace to Theodoric III., King of Neustria and Burgundy, whom he now set up as king over Austrasia also, so that the whole Frankish Empire was again united. Under the *fauldants* Theodoric and his successors, P. ruled the whole Frankish race in Austrasia as duke, in Neustria and Burgundy as mayor of the palace. After many wars with the Allemani, the Bavarians, and the Frisians, he died in 714, bequeathing his power to his grandson Theodebald, a child of six years, but in three years the child was dead, and Karl Martel (q. v.), a natural son of P., became duke of the Austrasian Franks.—**P. the Short**, so called from his stature, was the younger of the two legitimate sons of Karl Martel, and on the death of the latter (741) received dominion over Neustria, Burgundy, and Provence, while to Karlmann, the elder, fell Austrasia, with Suabia and Thuringia. For seven years the Frankish throne had remained unoccupied, when in 743 Karlmann and P. placed on it Hilderik III., last of the Meroving kings. In his name the brothers ruled, each in his district, under the old title of mayors of the palace, and as 'dukes and princes of the Franks' (*duces et principes Francorum*), like their father and grandfather. After six years of successful rule in peace and war, Karlmann grew weary of the world, and built a cloister for himself on Mount Soracte, 26 miles to the N. of Rome, which, later on, he left for the monastery of St. Benedict, on Monte Casino. His son and successor Drago was soon set aside, and P. became sole duke of the Franks. There was now but one step between him and the throne. With the consent of the leudes he sent to Rome Burkhard, Bishop of Wurzburg, and Fulrad, Abbot of St. Denis, his chaplain, and in 752 they returned with the reply of Pope Zachary to P.'s question, Whether or not it were a good thing that in the Frankish kingdom there should be kings who had not the royal power? The Pope's reply was, 'He who has the power, ought also to have the name, of king; and a clause appended ran thus:—'If you will smite the Lombard, we will transfer to you the seigniorial rights once belonging to the emperors, and now in abeyance.' P. then deposed Hilderik, and placed him in the convent of St. Omer, where in two years he died. And now P., the choice of the leudes and the people, was crowned and anointed king by the famous Boniface (q. v.) at Soissons (752). The year following, Ataulf (Adolphus), King of the Lombards, having seized Ravenna and marched on Rome, Pope Stephen II. (or III.) fled over the Alps to seek the help of P., who received him with the utmost reverence, and was recrowned by the holy father in Rheims Cathedral with the most sacred ceremonies of the Church (754). P. and his sons Karl and Karlmann were named 'Patricians of Rome,' the royal title being henceforth *Rex Francorum et Patricius Romanorum*, and excommunication was threatened against all who at any time should withdraw allegiance from their dynasty. Crossing the Alps, P. overcame the Lombard, and deprived him of the Exarchate of Ravenna, which he presented to the Pope and the Republic of Rome (755). From this 'donation

of P. dates the temporal power of the Roman Pontiff. No sooner had the Franks retired than Ataulf again took courage and advanced on Rome. P. returned to Italy, and enforced another peace (756), in which Ataulf pledged himself to pay him tribute, and yielded the Exarchate and the Pentapolis (comprising Rimini, Pesaro, Fano, Sinigaglia, and Ancona), which were confirmed to the Pope. P. now bent all his energies to the consolidation of his empire. To this end his friendly relations with the bishops greatly contributed. In eight years he had to repress repeated risings in Gascony and Aquitaine, till in 768 Waifer, their leader, was betrayed and slain. After a seven years' siege the Arabs were driven from their capital, Narbonne, and Gaul was free of the Saracen (759). Odilo, Duke of the Bavarians, who had married Hiltrude, daughter of Karl Martel, had in 741 made himself independent, but was in 743 vanquished by P. and Karlmann. His son and successor, Thassilo, on attaining majority (757), swore allegiance to P. at Compiègne; but during the wars in Aquitaine he freed himself of the Frankish yoke. After dividing his empire between his sons Karl the Great (q. v.) and Karlmann, P. died at Paris, 24th September 768, and was buried at St. Denis.—P., second son of Karl the Great, born 776, was anointed by the Pope King of the Lombards, acted as temporary Governor of Italy, and died in 810.—P., second son of Hlodwig the Pious, was appointed by his father King of Aquitaine (815), and played an important part in the civil war between his father and his brothers, till his death (December 838), when Hlodwig gave his dominions to his other son, Karl the Bald. The people of Aquitaine, however, supported P. the Younger, a son of the former king, who, after changing fortunes, was betrayed to Karl the Bald in 864, who cast him into prison, where he died. See Gfrörer, *Geschichte der ost- und westfränkischen Karolinger* (2 vols. Freiburg, 1848); Thierry, *Recits des temps Mérovingiens* (Par. 1839); Warnkönig and Gérard, *Histoire des Carolingiens* (2 vols. Brus. 1862); Bonnell, *Die Anfänge des Karolingischen Hauses* (Berl. 1866); Kitchin's *History of France* (vol. i. 1873).

Piquet (Fr.), a game of cards requiring the court-cards, the ace, the ten, nine, eight, and seven of each suit, and played between two persons. After dealing the cards in twos till each player has twelve, the rest, a talon or stock of eight, are laid on the table. The older hand (the dealer is the younger), must then lay aside from one to five of his cards, rejecting the poorest, and regularly replacing them from the talon. His opponent similarly 'discards,' but only if he chooses. Tricks are then taken in the usual way by the superior cards of the same suit, the ace being higher than the king, the king than the queen, &c. In reckoning what is called the point, the ace counts eleven, the king, queen, and knave ten each, and the plain cards according to the number of pips. The number of points in each game is 100, and 50 saves the lurch. The score is made up by reckoning carte-blanche, the point, the sequence, the quatorze, the cards, and the capot. Carte-blanche is the name of a hand which contains no picture-cards, and counts 10 points. The point goes to the player who has the greatest number of cards in any one suit, or if both hands are thus alike, the best hand of the two high suits, counting aces eleven, face-cards ten each, and plain cards according to the number of pips. The higher hand scores the number of cards in his fullest suit. Sequence is the greatest number of consecutive cards in any one suit; should the two players have an equal number, however, the winner is he whose sequence begins with the highest card. The sequence of three cards counts 3, of four cards 4, of five 15, of six 16, of seven 17, &c. For quatorze, four equal honour-cards, the highest scores 4; if there is no set of four, the highest set of three scores 3, &c. Each player counts 1 for each lead, and the second player counts 1 if he takes a trick. The larger number of tricks gives 10 for 'cards,' the whole tricks falling to one player gives 40 additional or 'capot.' If the first player makes 29 by preliminary scores, and 1 by first lead, he counts 30 more by 'piquet,' and if his first score comes up 30 before his lead, he scores 60 more by 're-pique.' There are, however, other ways of scoring.

Piquet, or **Picket**, is the name given to a small military outpost, placed to watch against surprises, and to oppose reconnoitring parties of the enemy.

Pique-Work (Fr. *piqué*, 'pricked'), a term applied to very minute inlays of metal and sometimes of stained ivory in surfaces

of wood, bone, and ivory. It is often seen on German powder-flasks of the 17th and 18th centuries.

Pirany (from *pirate*; Lat. *pirata*, Gr. *petraia*, 'one who attempts' to seize vessels). This being a crime by the law of all nations, a piratical ship may be captured by the vessel of any State, and the pirates may be brought to trial within its territorial jurisdiction. By the law of England, simple P. is punishable with penal servitude for life, or for a minor term; but if there has been any dangerous wound inflicted or murder caused by the act, the penalty is death. Persons engaged in the African slave trade are by statute guilty of P., and treaties in accordance have been entered into between the United Kingdom and the United States. Germany, Russia, and Austria have declared the same law.

Piræus, a seaport of Greece, 7 miles W.S.W. of Athens by rail, has five churches, three schools, an exchange (1873), and extensive waterworks (1876). In 1873 there were twenty-five factories, employing 2500 hands, iron-foundries, steam flour-mills, glassworks, cotton and silk mills. The workmen at the Bonianachi pottery are mostly natives of Staffordshire. Exclusive of coasters, there entered (1876) 1064 vessels, of 547,118 tons, and cleared 1049, of 541,989 tons. The exports (lead, zinc, and calamine) amounted in that year to £511,503; the imports (coal, coke, iron, spirits, and manufactured goods) to £983,210. Pop. (1871) 10,963. The P. was also the harbour of ancient Athens (q. v.), with which it was connected by the 'Long Walls,' traces of which may still be seen. The present town is wholly modern, dating only from 1835.

Pirano, a seaport of the Austrian markgratdom of Istria, finely situated in the Bay of Lagoon, 8 miles S.W. of Trieste. It has a fine Gothic church, a rathaus, Minorite convent, and an old castle standing amid olive groves. It affords safe anchorage, has several dockyards, and is a place of considerable commerce, chiefly in corn, wine, oil, and salt. Pop. (1870) 7691.

Piraya, or **Pirai** (*Serrasalpinx Piraya*), a Teleostean fish formerly ranked with the salmon genus, but separated from that group, and distinguished by triangular flat-edged teeth in both jaws, these organs being disposed in a linear series. The body is more compressed than in the salmon, and the abdomen is serrated. This fish occurs in the rivers of Brazil and Guiana. It is said to be exceedingly voracious, and to occur in great shoals. The Indians are said—but the statement like others relating to the voracity of these fishes requires verification—to place their dead in the rivers inhabited by the P. with the result that the flesh is cleaned from the bones and the bones obtained for burial in the space of a single night. The P. attains a length of a foot or more. Its teeth are used by the Indians in the manufacture of arrows and other offensive weapons. The fish is captured by the aid of hook and line, and also shot by means of arrows.

Pirmasens ('Sancti Firminii Sedes'), a town of S.W. Germany, in the Bavarian Palatinate, 37 miles W.S.W. of Speyer, with manufactures of shoes, musical instruments, leather, straw hats, and glassware. Pop. (1875) 8563.

Pirna, a town of Germany, in Saxony, situated on the left bank of the Elbe, 11 miles S.E. of Dresden by rail. It has eight churches, important river traffic, large sandstone quarries, and manufactures woollens, hosiery, earthenware, and beet-sugar. Its former citadel, *Sonnenstein*, is now a lunatic asylum. Near P. the Saxon army was forced to capitulate (15th October 1756) at the beginning of the Seven Years' War. Pop. (1875) 10,581.

Pisa, one of the oldest and finest cities of Italy, capital of a province of the same name, lies in a fertile valley on both banks of the river Arno, 6 miles from its mouth, and 12 N.N.W. of Leghorn by rail. It is surrounded by walls with five towers about 4½ miles in circumference, and divided into two unequal parts by the Arno, which is crossed by three bridges besides the railway bridge, and along both banks of which runs the Lung' Arno, the finest and most frequented street. On the N. side of this street are the chief hotels, and here every three years, on the 17th June, the famous illumination, *La Luminara*, takes place. P. has broad, level, and well-paved streets, and several fine squares, of which the most central is Piazza dei Cavalieri, the forum of the ancient republic, in which is a colossal

marble statue of the Grand Duke Cosmo, of 1596. It also contains the church of S. Stefano di Cavalieri (1565-96), adorned with Turkish trophies, ceiling paintings of the battle of Lepanto, and the largest organ in Italy; and a palace, on the site of the 'Tower of Hunger' (properly *Torre dei Gualandi alle Sette Vie*), rendered famous by Dante, in which Count Ugolino, his sons, and nephews, were starved to death for treason in 1288. In the N.E. quarter of the town is the Piazza di S. Caterina—an oval, surrounded with acacias and plane-trees, and embellished with a statue of the Grand Duke Leopold I., erected in 1832, and containing the church of S. Caterina, erected in 1253. In the N.W. quarter is the Piazza del Duomo, which has the finest buildings in P.; among these is the Cathedral, erected in 1063, and consecrated by Pope Gelasius II. in 1118. It is a basilica, in the Tuscan style, with nave and double aisles, and transept flanked with aisles, 312 feet long, 106 feet broad, and covered with an elliptical dome over the centre. It is built entirely of white marble, and is very rich in works of art. The Baptistery, or Church of St. John, opposite the Cathedral, was begun in 1153 and completed in 1278. It is circular, 101 feet in diameter, and covered with a conical dome 190 feet high, restored in 1856. The campanile or belfry, begun 1174, completed 1350, rises in eight storeys, surrounded by half-columns and six colonnades. It is 179 feet high, and from its deflection from the perpendicular of 13 feet, is called the Leaning Tower. It has a staircase of 294 steps, and contains seven bells. In the same quarter of the city is the Campo Santo, or burial-ground, laid out 1188-1200, to which fifty-three shiploads of earth were brought from Mount Calvary. It is surrounded by a cloistered structure in the Gothic-Tuscan style, the whole forming a parallelogram. Three chapels adjoin it, rich in paintings of the Tuscan school of the 14th and 15th centuries. P. has altogether more than seventy churches, among which, besides those already mentioned, may be specially noted those of S. Francesco, S. Michele in Borgo, in the Gothic style of the 13th c., S. Nicola, founded in 1000, S. Maria della Spina, in the French Gothic style, erected 1230, and rebuilt on a different site 1874, and S. Paolo a Ripa d'Arno, of the 12th c. The Accademia delle Belle Arti, founded by Napoleon, contains many fine paintings of the early Pisan and Florentine schools. La Sapienza, the University, founded about 1160, was famous during the Middle Ages, and has now 60 professors and 600 students. The building dates from 1493, and has a fine Renaissance court, with a statue of Galileo, who was born at P. in 1564, and was appointed professor of mathematics here in 1610. It has a library of 50,000 volumes, and many rare manuscripts, also a museum of natural history and a botanic garden, founded in 1544. About 3½ miles from P., at the foot of the Monti Pisani, are the Bagni di San Giuliano, known to the ancients, and still frequented in summer. The water in the springs varies in temperature from 82° F. to 104° F. The baths and the mild climate which P. enjoys attract many visitors and patients suffering from pulmonary complaints. P. manufactures soap, straw-paper, and glass. The pop., which in the 13th c. amounted to 150,000, is given by the *Almanach de Gotha* (1878) at 23,906.

P. (Lat. *Pisa*), an ancient Etruscan city, became a Roman colony B.C. 180. It was named by Augustus, Colonia Julia Pisana, and during the Empire was a place of some importance; but the only traces of Roman power which remain are a few remains of baths (Bagni di Nerone) near Porta Lucca. Early in the 11th c. P. had become one of the most powerful cities of Italy. In 1025 the Pisans drove the Saracens out of Sardinia, and colonised the island. They defeated them in 1030 and 1089 at Tunis, and in 1063 destroyed their fleet at Palermo. In 1114 they conquered the Balearic Islands, and shared in the commercial prosperity that the Italian maritime cities enjoyed after the Crusades. During the 12th c. their power was at its height, and they fought many victorious battles both by land and sea, taking Majorca from the Saracen pirates, and defeating Lucca after a long-continued struggle. In this war Florence was the ally of P., and inflicted a severe defeat on Siena, which took the other side. P. adhered to the party of the Ghibellines, and suffered severely in the struggle with Genoa, being disastrously defeated by the Genoese in 1284 off the island of Meloria, the scene of its victory over the Genoese fleet forty-three years before. From this blow P. never recovered. It lost Corsica in 1300, and Sardinia in 1320, and becoming weakened by internal dissensions, fell under Castucci, Agnello, Cian-Galeazzo, and lastly Gabriello Visconti,

who sold it to Florence in 1406. The resistance of the inhabitants was ineffectual, and many of them left the city, all the trade and wealth of which had passed away with its independence. Its liberty was restored by Charles VIII. of France, after ninety years of Florentine rule. The inhabitants resisted many attempts of the Florentines to regain the city, being helped by Genoa, Siena, and Lucca, but in 1509 the Florentines bribed Louis XII. of France to withhold his aid, and after a siege which had lasted intermittently for fifteen years, captured the city. Once more, though the conqueror's terms were easy, thousands of the high-spirited Pisans voluntarily left their homes rather than submit to the hated yoke. From this time it continued subject to Florence. It finally came, with the rest of Tuscany, to the kingdom of Italy in 1860. See Nistri, *Guida di P.* (Pisa, 1845); Rohault de Fleury, *Les Monuments de Pise au Moyen Age* (Par. 1866, with Atlas); and E. Valtancoli-Montazio, *Annali di P.* (Lucca, 1842-45).

Pisa, Council of, a council held at Pisa in 1409, to end the schism which had distracted the Western Church, and to decide on the claims of the two rival Popes, or, as Gibbon finely puts it, 'to heal the wounds and restore the monarchy of the Church.' These were Benedict XIII., the creature of the French King, and Gregory XII., successor of Innocent VII. Both agreed to a general council, but both did everything in their power to prevent its meeting. However, the cardinals of each party united in summoning it, and Benedict and Gregory were cited to attend, but neither appeared in person. The council was opened, March 25, 1409, with 22 cardinals, 12 archbishops, and 80 bishops, and with the representatives of 12 archbishops and 102 bishops. The result of the inquiry was that Benedict and Gregory were both deposed, and a new Pope, who took the name of Alexander V., was elected. The Council of P., as also those of Constance and Basel, is appealed to by those who believe a general council to be superior to a Pope, but the Ultramontanes deny that any precedent has been established, asserting that the means resorted to in special emergencies cannot be allowed to regulate the course of ordinary affairs.

Pisciculture is the art of breeding fishes artificially. Most writers agree in assigning its origin to the Chinese, a supposition supported by the fact that at the present day it is practised in a most scientific and advanced fashion in the Celestial Empire. We know that the Romans attained great proficiency in some phases of the art of P. Various accounts of their piscicultural establishments prove that they carried out its practice in a very complete fashion. Thus Lucullus had fish-ponds the value or cost of which amounted to upwards of £30,000. The preference of the ancient Romans for certain fishes (such as mullet, carp, &c.), and the immense sums which were paid for these, may serve to explain the rise and progress of P. among the ancients. The Chinese, it is certain, knew the art of artificially impregnating the eggs of fishes by bringing the *milt* in contact with the *roe*; and in this respect they appear to have been considerably in advance of the Romans, since, as far as can be ascertained, the P. of the latter was to a large extent limited to the preservation of fishes which had been previously obtained from their native waters. The art of P. proper, it need hardly be said, deals with the manipulation and preservation of the eggs, with the best method of obtaining them from the female, and, above all, with the after treatment of the eggs, and with the conditions which most favourably affect their due development. The rearing of young fishes forms a branch of P. of no less importance than their care during their early development, or the transportation of the eggs under favourable conditions to foreign countries for hatching and acclimatisation in their rivers or seas. It appears probable that a German, Jacobi by name, was one of the first, if not actually the first, to experiment on the artificial spawning of fishes. He observed that the male fishes impregnated the eggs previously deposited by the females by simply shedding the milt over them; and having learned this much from observation, Jacobi proceeded to experiment upon the artificial impregnation of fish-eggs by manipulating the body of the male fish so as to cause the milt to be extruded on the spawn of the female. The value of Jacobi's researches was fully recognised by the German Government. A French peasant named Joseph Remy, living in the department of Vosges, made a series of similar experiments in 1849. He was fortunate enough to attract the notice of a Dr. Haze of Epinal, who brought

scientific knowledge to supplement the practical experience of Leamy, who in his work had been aided by a neighbour named Gatin. The labours of these experimenters also met with due recognition from the French Academy of Sciences. Shaw of Drumlanrig experimented before 1840 on the artificial culture of salmon ova, and published in that year a treatise on the subject of P.; while among other names familiar in this country as cultivators of this art may be mentioned those of Young, Buist, Francis, and Buckland—the last of whom, as an inspector of salmon fisheries, as well as from independent research, being a familiar authority on the subject. In Britain the salmon and trout are the only fishes the artificial breeding of which has received much attention. Pond fish, such as pike, perch, carp, &c., are simply kept in artificial waters and are allowed to breed without any supervision being exercised over their increase. But there can be little doubt that a rich pecuniary harvest awaits the investigator who, bringing practical experience, energy, and capital to the work, should institute experimentation in P. on a large and extensive scale with a view to the increase of the supply both of freshwater and marine fishes.

The impregnation of the eggs is the preliminary stage of P. This is secured by obtaining the female fishes—in the case of salmon—as they are swimming up the rivers for the purpose of spawning. The fish is then held gently but firmly in a tub of water, and the hand of the operator passed gently along the belly, so as to cause the extrusion of the eggs. A male fish is then similarly manipulated, with the effect of shedding the milt over the roe; the occurrence of impregnation being marked by the brilliant pink colour which the eggs assume. The next thing to be done is to surround the eggs with conditions approaching as nearly as possible to those of nature. Various forms of breeding troughs and boxes are used, and the supply of water, temperature, and other details have to be carefully calculated and determined, so as to ensure the due development of the young progeny. After hatching even greater care has to be exercised in connection with the preservation, food, &c., of the young fishes. One of the best known piscicultural establishments is that at Huingue on the Rhine, formed by the Emperor Napoleon; that at Buisse in Isère is hardly less celebrated. In Scotland, the Stormontfield breeding-ponds, near Perth, are well known. This establishment was founded in 1852. The following remarks, penned in 1866 by the late Mr. Robert Buist, who was the first superintendent of the Stormontfield ponds, will serve to show the advantages derived from the artificial cultivation of salmon. Mr. Buist writes: 'The works at Stormontfield are at length placed in a position whereby fair scope will be given to our operations, and the fruit of our attempt to improve the fishings be more clearly seen. After the expenses of the new work are defrayed, the annual outlay will not be higher than it was before, and the matter of from £70 to £100 will be sufficient for carrying out all the purposes required. Finally, from the experience of upwards of fifty-five years on the Tay, and several years on other rivers, I would strongly recommend to all proprietors of salmon rivers to follow the example now set by the Tay proprietors in regard to P., the outlay being trivial, and the benefits that may ultimately accrue being very great.' Mr. Buist's table of the increase of the Tay rental since 1853 shows that in 1854 the rental was £9269. In 1865 it had increased, through the rich cultivation of the salmon, to £17,618. It is a noteworthy fact, in connection with the artificial culture of the salmon, that whilst out of 3000 eggs naturally deposited in rivers only one salmon on an average is developed, over 1000 'smolts' will be artificially hatched, produced, and sent to the sea from the same number by artificial propagation. In Mr. Buckland's 'Museum of Economic Fish Culture' at S. Kensington, the breeding boxes are formed of slate troughs, arranged like steps and stairs, one above the other, so as to admit of a continuous flow of fresh water passing through them. Each trough is 3 feet 2 inches long, 7 inches wide, and 7 inches in depth. The 'bottom' consists of gravel, cleansed and freed from insect larvæ, which are found to be pernicious enemies of the pisciculturist.

Piscina (Lat. 'a fish-pond') was a name applied by the Romans to any kind of reservoir, especially those connected with the aqueducts and the public baths. In the baptisteries erected near the early Christian churches, the P. was a deep basin, to which several steps descended, and in which persons

received baptism by immersion. In Catholic churches the P. is a shallow stone basin with a drain from it, and is used by the priest to wash his hands in during mass, or to cleanse the sacred vessels after mass. It is usually placed within a niche, at a convenient height above the floor. In England the P. is almost always on the S. of the altar. It is seldom found of an earlier date than the 13th c.

Pis'ek (Boh. *Pisek*), a town of Bohemia, on the Wottawa, a tributary of the Moldau, lies in a sandy plain. It is of very ancient date, and contains a curious old bridge and the remains of an ancient castle. The chief manufactures are woollen cloth, colours, and musical instruments. Pop. (1869) 9071.

Pisistratus. See PEISISTRATOS.

Pis'olite, or **Pea-Stone**, is a variety of Oolite, in which the concretions are as large as peas. The *pea grit* of Cheltenham is a pisolitic limestone.

Pista'cia is a genus of trees or shrubs belonging to the natural order *Anacardiaceæ*. They have alternate pinnate or trifoliate leaves without stipules, small unisexual dioecious apetalous flowers in axillary racemes or panicles, fruit a drupe with a hard, bony kernel, and seed with thick, often green cotyledons filled with fat oil. *P. vera*, a small tree, native of Western Asia, and now long cultivated in Sicily and other parts of S. Europe, yields pistachio-nuts, which are much esteemed by the Greeks and Turks both in a dried state like almonds, and made into conserves and articles of confectionery. An oil is expressed from the seed. *P. Lentiscus*, an evergreen shrub of the Mediterranean region, yields mastich or Mastic (q. v.). *P. Terebinthus*, a small tree of S. Europe, N. Africa, and Western Asia, furnishes Chios or Cyprus turpentine, used medicinally and for flavouring wines and cordials in Greece. It is obtained by making incisions in the trunk, from which the turpentine flows, and becomes hardened by exposure. Galls collected from this tree are employed for dyeing and tanning purposes—a morocco leather being prepared with them. The heart-wood of *P. integerrima*, a tree of about 40 feet in height, frequent in parts of India, is the best and most handsome wood of N.W. Himalaya for carving, furniture, and all kinds of ornamental work. It is durable, hard, close and even-grained, brown, beautifully mottled with yellow and dark veins, and takes a fine polish. The fruit and large gall-like excrescences from the leaves are used in medicine. Various other species of the genus give useful products, and it is represented both in Mexico and China in addition to the range above indicated.

Pis'til is the female organ of a flowering plant, placed in the centre of the flower (i. e., constitutes its innermost whorl), and consists of one or more *carpels*, each containing the germ of one or more seeds. The carpels are usually sessile and alternate with the inner row of stamens. In the most perfect form each one consists of three parts—(1) the **OVARY** or enlarged base, which includes one or more cavities called *cells*, containing one or more small bodies called *Ovules* (q. v.); (2) the **STYLE**, proceeding from the summit of the ovary; (3) the **STIGMA**, surmounting the style, and varying greatly in form. The style is often wanting, the stigma then being sessile on the ovary; but in the fertile P. there must be at least one ovule in the ovary, and some portion of stigmatic surface. This surface, which is variously adapted for the retention of the fecundating material from the Stamen (q. v.), is composed of a loosely cellular substance, destitute of epidermis, and usually in communication with the ovary by a channel. Some of the different forms assumed by the stigma are thus defined: *capitate*, when a small head as in the primrose; *punctiform*, when a point; *plumose*, when feathery as in grasses; *petaloid*, when shield-like as in the poppy; *petaloid*, as in iris, &c. When the P. consists of a single simple carpel, it is *monocarpellary*; if of two, three, or an indefinite number of carpels, whether separate or united, it is *bi-tri- to poly-carpellary*; when the carpels or their ovaries are more or less united into one compound ovary, it is *syncarpous*; when the carpels or ovaries are all free and distinct, it is *apocarpous*. A compound ovary may be *unilocular* or one-celled; or *plurilocular* or several-celled, when completely divided into two or more cells by partitions called *dissepiments* (septa), usually vertical and radiating from the axis of the ovary to its circumference. In general, the number of cells or of dissepiments, complete or

partial, or of rows of ovules, corresponds with that of the carpels of which the P. is composed. In apocarpous P. the styles are usually free, each bearing its own stigma. Syncarpous P. may have several styles (when the styles are free from the base); one style, with several branches; one simple style, with several stigmas; or one simple style, with a branched, lobed, toothed, notched, or entire stigma. In general, the number of styles, or branches of the style or the stigma, is the same as that of the carpels. See PLACENTA.

Pistillidium is a name that has been applied to what is more frequently termed the *Archegonia* of cryptogamic plants, a structure of analogous functions to the pistil or female organ of phanerogamia. In Mosses (q. v.) or Hepaticae, for instance, it is a flask-shaped structure, enclosing near its base a large central cell, in which is formed the *oosphere*, to which an entrance is obtained by the *spermatozoid* (see PHYTOZOA) from the *antheridium*; and the result is the development of the *sporangium* or *spore-case*.

Pistoja, an interesting old town of N. Italy, province of Florence, is situated in a fertile district, on an elevation near the foot of the Apennines, and overlooking the Ombrone, a small affluent of the Arno, 21 miles N.W. of Florence by rail. It is nearly quadrangular in outline, and is gut by high, well-preserved walls, at the S.E. extremity of which is the strong *Fortezza* and the Campo Marzio. The cathedral of St. Jacopo, dating from the 12th c., and remodelled in the 13th c., contains a rich 'silver altar' (wrought in silver and gilded) by Simone di Ser Memmo and other masters, many fine monuments, frescoes, and terra cotta bas-reliefs. The interior was much marred by alterations in 1838-39. Other notable churches are the Romanesque St. Giovanni Fuoricivitas, erected about 1160, with an ornate façade adorned with rows of columns; the octagonal Battistero (1339), in Italian Gothic style; St. Andrea, of the 12th c., with sculptures of 1166 on the architrave of the entrances; St. Maria dell'Umiltà (1509), designed by Ventura Vitoni, a pupil of Bramante, the dome by Vasari; and St. Domenico (1380), containing paintings by Fra Bartolommeo (?), Ghirlandajo, &c. These churches can boast many of the earliest attempts at sculpture in Tuscany, and the work of several of the oldest artists (e.g., Giammons and Adesdatus). P. has also a Palazzo Pretorio, of the 14th c., now the seat of the law courts; an Ospedale del Ceppo of 1277, with a beautiful frieze, bearing coloured and glazed reliefs in terra cotta; and two libraries, the Fabbroniana and Fortiguerri, founded by and named after two cardinals who were born here. The Villa Puccini, a mile N., has works of art by Pampaloni and others, and stands amid fine gardens. P. has important manufactures of guns, iron and steel wares, and paper. Pop. (1874) 12,966. P. is the Roman *Pistoria*, near which Cataline was defeated and slain, B.C. 62. In the Middle Ages it was the centre of the fiercest struggles between Guelphs and Ghibellines. The Black and White parties (*Cancellieri* and *Pancinichi*), which extended their intrigues to Florence, were formed here in 1300. P. surrendered to Florence in 1351, and although its prosperity continued, became in art as well as in politics a mere pendant of the greater city.

Pistol, the smallest form of firearm, invented in Italy about 1520. The name is commonly said to be derived from Pistoja, a town in Tuscany, but Demmin (*Weapons of War*) mentions Perugia, and not Pistoja, as the first place of manufacture, and finds in the Italian word *pistallo*, 'a pommel,' a probable root. The oldest known examples of the P. all possess wheel-locks;

Wheel-lock Pistol, time of Elizabeth.

no matchlock P. has been met with. In the hands of the Ritter or German knights, the P. proved more effective than the lance, 118

and led to its disuse. French and English horsemen armed with the P. were termed *pistobers*. The service P. of English lancers is 13½ inches long, and weighs 40 ounces; the barrel, 8 inches long, has a calibre of .577 inch and 5 grooves. Birmingham in England, Liege in Belgium, and Norwich in Connecticut, U.S., are the great seats of the P. manufacture. See REVOLVER.

Pistole (derivation unknown), the name of a gold coin introduced into Spain in the 16th c. Until 1728 it was an irregular piece of money, but thereafter it received a definite form and value. The value has, however, been very variable, not only in Spain, but in the other countries which adopted it—Italy, Switzerland, and various parts of Germany. Though not now recognised in any national currency, the coin still lingers in these lands. In many parts of Germany it has a value of about 8s. 6d. sterling.

Pisum. See PFA.

Pit, in gardening, is a low structure with a roof of glass, or of other material, such as frames of reeds or boards, raised on walls made of brick or thick turf. What is called a 'cold-P.', has no artificial source of heat. It is used for protecting potted plants that are not in a growing state, or for preserving culinary vegetables from the frost. When artificial heat is required, it is obtained by a bed of bark within, and an exterior appliance of fermenting manure, or by fire-heat through flues.

Pita—flax, thread, or hemp—are fibres of species of *Agave* (q. v.).

Pitakā ('basket or collection'), the name of the three sacred books (Tri-pitaka) of the Buddhists of Ceylon, consisting of (1) the Vinaya P., which treats of the discipline of the monastic order; (2) the Sutra P., or discourses for the laity; (3) the Abhidharma P., or metaphysics. They are written in the Pāli Language (q. v.) on palm leaves. Portions have been translated by Burnouf, Fausbøll of Copenhagen, and Gogerly; but the entire series, which is estimated to be about twice as long as the Bible, has not yet been printed. It is generally admitted that the present text is identical with that settled by the Council at Patna about 250 B.C.; but it was not reduced into writing till 160 years afterwards, at the same time as the Commentaries. In 1875 this text was carefully revised by a great assembly of learned monks at Ratnapura in Ceylon. The *dharma-pada*, or 'scripture verses,' has been translated into English by Professor Max Müller as an Introduction to Captain Rogers' *Buddhaghosha's Parables* (Lond. 1870). See also Burnouf's *Introduction à l'Étude du Bouddhisme* (Par. 1845); the late Professor Childers' *Pali Dictionary*, and Rhys Davids' *Buddhism* (1877).

Pitcairn Island, a solitary islet in the S. Pacific, situated in 25° 4' S. lat., 130° 8' W. long., and only 4½ miles in circumference. It is of volcanic origin, and the surface is very rugged, the highest point being 1008 feet above the sea level. The shores are precipitous and unsheltered by reefs, so that landing is difficult and often dangerous. The island is moderately fertile, producing the bread-fruit, cocoa-nut palm, banana, yams, sweet potatoes, and sugar-cane. Sheep, wild goats, pigs, and rats are the principal animals. The mean temperature in winter is 65°, and in summer 82°. P. I. was discovered in 1767 by a young man attached to Carteret's expedition, and was named after the discoverer. The chief interest attaching to it is in connection with the mutiny of the *Bounty* (q. v.). In 1790 nine of the mutineers, accompanied by six Tahitian men and twelve Tahitian women, with one infant, landed on P. I., but in consequence of perpetual violent quarrels, in ten years all the men, save one of the mutineers named Adams, had died; only one out of the fourteen dying a natural death. Under the guardianship of Adams, who became a changed character, the young community grew up a pattern of good morals. Its existence was first discovered in 1808 by an American merchant vessel, and thereafter British men-of-war touched at the island at intervals. In 1831 the islanders, numbering 87, were voluntarily conveyed to Tahiti, where they were liberally treated, but disgusted with the morals of that island, most of them returned in nine months. In 1839, at their request, Captain Elliot of H.M.S. *Fly* took possession of P. I. in the name of Great Britain, and drew up a code of laws for the inhabitants. In 1856, in consequence of the scarcity of food, the islanders, who then

numbered 194, together with nearly all their live stock and effects, were removed at their own request to Norfolk Island (q. v.), whence seventeen of them returned to P. I. in 1859. The community possessing these remarkable antecedents is distinguished by its simplicity, purity, and loyalty. Education is universal, and innocent amusements are largely indulged in. Captain Moresby, R. N., who visited the islanders in 1871, while admitting that the passive virtues abound amongst them, adds that 'a development of mental muscle is needed to make them systematically energetic, industrious, and persevering.' At the present time P. I. is visited principally by whalers in need of fresh water and provisions. Agriculture and fishing are the chief occupations of its now scanty inhabitants.

Pitcairne, Archibald, a Scotch physician, born at Edinburgh, 25th December 1652, studied at the university of his native city and at Paris, and acquired a wide reputation at home as a practising physician. His celebrity even secured him 'a professorship' in Leyden University, which, however, he held only for a year. He died 20th October 1713, and was buried in Greyfriars' Churchyard. P.'s chief professional work, *Elementa Medicinæ Physico-Mathematicæ* (1718), consists of his Leyden lectures. It was long a standard treatise on its subject. The author was an ardent disciple of Harvey in his great doctrine of the circulation of the blood. An elegant scholar, and a verse-maker of some skill, P. occasionally employed his leisure in irritating his Presbyterian countrymen by satirical effusions which exposed him to the charges of atheism and impiety.

Pitch is the black solid shining residue from the distillation of tar after that substance has yielded up first its light oils or naphtha, and next its heavy or carbolic acid oils and anthracen compounds. P. is used for coating ironwork to prevent its oxidation, for coating the hulls of vessels, for making artificial asphalt pavements, and for various other purposes. The concrete resinous exudation from the pine *Abies excelsa* is known as Burgundy P., and is extensively employed in medicine and the arts. Natural asphaltum and hard bitumen are also called P., and the product of the asphalt lake of Trinidad and a similar deposit from Cuba are very similar in physical properties to common P.

Pitch (in music), the acuteness or gravity of a sound as determined by the number of vibrations of the air caused in producing it. In stringed instruments it is dependent on the length, weight, and tension of the strings operated on; in wind instruments, on the size of the column of air employed (see article MUSIC). The P. of musical notes has varied much at different times and in different countries, and every attempt at universal agreement has hitherto failed. The following table gives the P. in use at certain times and places for the notes middle A and C—

	A	C
Paris, Grand Opera, 1699	404	459
Do. do. 1858	448	515
French 'Diapason Normal'	435	522
Mandell's Tuning Fork (1740)	419	...
London, Italian Opera (1859)	475	546
Scheibler's pitch, recommended by the Society of Arts	419	528

Pitch, Burgundy. See BURGUNDY PITCH.

Pitch-blende is a greyish, brownish, or velvety-black mineral, with a dull or submetallic lustre, occurring in botryoidal masses associated with ores of lead and silver in veins. It contains 80 to 87 per cent. of protoxide of uranium, is infusible before the blowpipe, and dissolves slowly (when powdered) in nitric acid. It is used in the arts for painting upon porcelain.

Pitcher Plant. See NEPENTHES.

Pitchstone, or Retenite, is a compact glassy rock, varying in colour from velvety-black through various shades of dirty green and yellow to an almost white. It has a splintery fracture. It frequently occurs in the form of dykes or intrusive sheets, and is sometimes no doubt the remnant of a *coulée* of some past geological age.

Pitchurn Beans. See PICHURIM.

Pith is a cylinder of cellular tissue, occupying the centre of the stem of an exogenous plant after the first year of its growth. It is active only in young stems or branches, becomes dried up and compressed as the wood hardens, and is often scarcely dis-

tinguishable in old trees. It is surrounded and encased by the medullary sheath which abounds in spiral vessels, and when young, is in direct communication with the leaf-buds, leaves, and other ramifications of the system. In the P. originate the medullary rays which form vertical plates radiating from it, traverse the wood, and terminate in the bark. They are formed of cellular tissue, keeping up a communication between the living portion of the centre of the stem and its outer surface. As the heart-wood is formed, the inner portion of the medullary rays cease to be active, but they may usually still be seen in old wood, forming what carpenters call the silver grain.

Pithe'cia. See SAKI.

Pithe'cus. See ORANG.

Pit'man, Isaac, born at Trowbridge, Wilts, January 4, 1813, was educated at the grammar-school of his native town, and at the Normal College of the British and Foreign School Society in London, became master of the British School at Barton-on-Humber, Lincolnshire (1832), and established a similar school at Wotton-under-Edge, Gloucestershire (1836), publishing his *Stenographic Sound-hand* (1837). He removed to Bath (1839), and there elaborated a phonetic system, which Max Müller pronounces the best of its kind, his *Phonography, or Writing of Sound*, appearing in 1840. In 1843 he founded the Phonetic Society and the Phonetic Institute, the latter a printing-office, from which have issued the *Phonographic Reporter's Companion* (1853), a large number of standard works in phonetic spelling, and the *Phonetic Journal*, a weekly paper, which in 1876 had reached a circulation of 9250. See PHONETIC WRITING.

Piton Bark. See CARIBEE BARK.

Pitt, Thomas, the founder of the famous family of English statesmen, was born at St. Mary's Blandford in 1653. Towards the close of the century he went to the East, and was governor of Fort St. George, Madras (1698-1702). In 1714 he was made governor of Jamaica. He sat in four Parliaments, and died 28th April 1726. The P. diamond is so called from having been in his possession. His son, **Robert P.** of Boconnoc in Cornwall (died 1727), was father of the illustrious Earl of Chatham (q. v.). — **William P.**, second son of the Earl of Chatham and of Lady Hester Grenville, was born 28th May 1759. He was remarkably precocious, taking as a boy keen interest in political affairs, but he was so frail in health that his education was conducted at home, under the tutorship of the Rev. Dr. Wilson, and the loving supervision of his distinguished father, who trained him in oratory and educated him for the service of the state. In 1773, when he entered Pembroke Hall, Cambridge, he exhibited a surprising knowledge of the classics. He had also a passion for mathematics, and was afterwards able to utilise the habit of mind developed in this study in discussions upon finance. Having graduated M.A., he proceeded to Lincoln's Inn, became a barrister in 1780, and went round the Western Circuit, as he was compelled to eke out his narrow income by practice. That same year he was defeated in his candidature for the University of Cambridge, but in January 1781 he was returned for the borough of Appleby, through the influence of Sir James Lowther. At this troublous time Lord North was in power, and there were two sections of the Opposition, headed respectively by Fox and Lord Shelburne. P. joined the latter, and on the 26th February made his first speech in favour of economical reform. This masterly effort, delivered with perfect self-possession, at once secured him a leading position in Parliament. But his success did not carry him off his feet. He spoke no more than twice again until the session ended. On the 27th November 1781, after Parliament met, he fairly established his reputation in the debate upon the address. Indignant at the abuses in the composition of Parliament, P. moved in 1782 for an inquiry into the state of representation, which, curiously enough, considering how long the subject afterwards slept, he only lost by 20 votes in a house of 300. When Lord Shelburne was called to the head of the Ministry, P., who had previously declined the Vice-Treasurership of Ireland, accepted the Chancellorship of the Exchequer in his twenty-fourth year. After concluding the Peace of Paris, the Shelburne Ministry came to an end, having been worsted by 'the Coalition,' which was a *rapprochement* of the Whig followers of Fox with the Tory supporters of Lord North. This ill-assorted union was strong in Parliament, but

was detested alike by the country and the king. In opposition P. again broached the subject of reform, but his motion was lost by a majority of two to one. Along with his friends Eliot and Wilberforce, he travelled to Paris in 1783, obtaining thereby his only glimpse of the Continent during his whole life. In December Fox was defeated on the India Bill, and P. accepted the post of First Lord of the Treasury, but he could not have held it had he not known that the country supported him. Addresses poured in upon him from Whigs and Tories alike, so that he felt justified in delaying dissolution of Parliament for five months, though opposed by the greatest orators of the day and beaten in sixteen divisions. At the general election P. was triumphantly supported throughout the great constituencies, and 160 of his previous opponents were unseated. He took up the premiership once more, and never was Minister in so powerful a position. He had annihilated the Whigs. The King felt bound to him by the ties of gratitude. The people were drawn to him because of his high disinterestedness and his patriotism. P.'s first great achievement, after an elevation to the premiership which lasted for seventeen years, was to make the administration of India a part of the general system of the English Government. In 1785 he devised a plan of Parliamentary reform, but the bill he brought in with the view of disfranchising thirty-six decayed boroughs was defeated by a combination of his own party with the Whigs. It has been said of P. that 'he is the first English Minister who really grasped the part which industry was to play in promoting the welfare of the world.' His efforts after financial reform and his general industrial policy were largely shaped upon the principles of Smith's *Wealth of Nations*, to which he had given long and diligent perusal. He took office at a moment when public credit was low, and his first measure—a plan of paying off the national debt by a sinking fund—though a failure, had the effect of restoring public confidence. He next attempted to 'draw what remained of the shattered empire together' by removing the harassing restrictions upon trade between England and Ireland. When that failed, he established in 1787 a treaty of commerce with France which removed every import duty. In 1788 he supported Wilberforce in his attacks upon the slave-trade. The same year, with the enthusiastic support of the great body of the nation, he resisted the Whig party in then attempt to create a regency during the King's madness, on the ground that the right to choose a temporary regent lay with Parliament. The first nine years of his premiership were peaceful and prosperous. Throughout the French Revolution P. pled for a preservation of friendship between the countries, and showed no alarm at the contagion of its principles. In the very heart of it he supported a Libel Bill of Fox's, by which the freedom of the press was finally secured. Even when the President of the French Convention had issued the war cry in the face of Europe, 'All governments are our enemies,' P. struggled to maintain peace. When, in 1793, France actually declared war, his influence was destined to decline, for though he gave fearless encouragement in the midst of disasters, his military administration did not maintain the promise of his earlier career. His generals were unsuccessful, his coalitions were failures. In 1799 he put into effect his scheme for fully conciliating Ireland by effecting its legislative union with England. His domestic policy became somewhat harsh and severe, but he never lost his sympathy with civil and religious liberty, and in February 1801 he resigned the premiership, on being foiled in his purpose of raising Catholics and Dissenters to perfect equality of civil rights. After a prolonged absence he reappeared in Parliament in May 1803, when he made a magnificent speech in favour of the war. In 1804 he was recalled to the Treasury. His wish that Fox and Grenville should join him was thwarted by the King, and singlehanded he had to face the brunt of the terrible Continental storm. The task was too much for his strength, and hastened his end. The coalition he formed with Russia and Austria was shattered by the victorious legions of France. On the 23d January 1806 he died at Putney, in the midst of the Napoleonic triumph. 'Austerlitz,' wrote Wilberforce, 'killed P.' P., says Lord Macaulay, was 'the greatest master of the whole art of Parliamentary government that ever existed.' As an orator he was remarkable for wealth of language, command of sarcasm and retort, and dignity of demeanour. He was a courageous and resolute Minister and an unequalled political leader. His triumphs in the House of Commons were great and continued, and even in dire disaster he retained the affection and

regard of the people. For twenty years he was the single hope and pilot of the country. In his foreign policy he did not display the shining talents of his father, but he inherited much of Chatham's genius—his splendid disinterestedness, his patriotism, and his pride. See Gifford's *Life of P.* (3 vols. Lond. 1814); Tomline's *Life of P.* (6 vols. Lond. 1815); Earl Stanhope's *Life of P.* (4 vols. Lond. 1861); 3d ed. 1867; May's *Constitutional History of England* (1865); *Jessie's Memoirs of Life and Reign of George III.* (1867); Lecky's *History of England in the 18th C.* (2 vols. 1878).

Pitt's, a genus of *Insectorial* birds, belonging to the *Dentirostris* group of the order, and including, among other forms, the Giant Ant-Thrush or Giant Breve (*P. banyanensis*), the Black-headed P. (*P. melanocephala*), and the Thomson-headed P. or Bradiyure (*P. granatica*). The true ant-thrushes are found in both Old and New Worlds; the breves are confined to the former.

Pittacus, one of the seven wise men of Greece, was born about 652 B.C., at Mitylene in Lesbos. Along with the brothers of Alceus, he slew the tyrant Melanchrus (612), commanded his fellow-countrymen in their war with the Athenians for the possession of Sigeum (606), and, on the expulsion of the aristocratic party from Lesbos, was chosen supreme ruler (589). After ten years' tenure he resigned his office, and, withdrawing into private life, died at a great age in 569. Four only out of 600 elegiac verses composed by P. are extant, but two of his maxims are still famous: 'Know the fitting time,' and 'Tis hard to be good.' See Bergk's *Poeta Lyrici Græci* (Leips. 1843).

Pittosporaceæ is a natural order of dicotyledonous trees, shrubs, or climbers, that have their headquarters in Australia, with outliers in Japan, Cape of Good Hope, the Canaries, &c., but none reaching America. The number of species is about a hundred. A few yield edible berries. The principal genera are *Pittosporum*, with flowers scented like the lily of the valley, *Bullardiera* (q. v.), and *Sollya*. Some of the last named, with pretty blue flowers, are well known in greenhouses as slender, ornamental, twining plants.

Pittsburg, a city of Pennsylvania, U.S., lies at the junction of the Alleghany and Monongahela rivers, which unite here to form the Ohio, and is 354 miles W. of Philadelphia by rail. On the opposite bank of the Monongahela is Alleghany City, which is connected with P. by six bridges, and which, though still possessing a separate municipal existence, is practically part of the latter. The city now covers the peninsula of level ground between the two rivers, and extends about 7 miles up the banks of both. It is well supplied with tramways, and gas is cheaper here than in any other town in America. There are 200 churches and three public libraries; and among the principal buildings may be mentioned the university, the observatory, and six hospitals. P. has (1878) ten daily newspapers, of which two are in German, and twenty weeklies. It is one of the most important manufacturing towns in the U.S. Coal and coke are produced annually to the amount of 4,000,000 tons, half of which is floated in barges to Cincinnati, Louisville, and New Orleans, when the rivers are in flood. The chief manufacture is iron. There are twelve blast furnaces, which in 1873 yielded 163,853 tons of pig metal. Nearly double this quantity has to be imported in addition, as in the same year there were forty-three iron mills, and seventy-five foundries and machine-shops, using 474,195 tons of pig metal in their manufactures. There were also seventy glassworks, employing 5000 men, three copper mills, ten white-lead factories, and two silver-melting furnaces, for extracting lead and silver from Rocky Mountain ores, besides a great number of smaller factories of various kinds. P. occupies the site of Fort Duquesne, built by the French in 1754. Four years later the French were expelled by the British under General Forbes, and a new fort was built, which was called Fort Pitt, in honour of William Pitt, then at the head of the British Ministry, and which has given its name to the town. Under British rule it soon became a trade centre. In 1804 it was incorporated into a borough, and in 1816 into a city. In July 1877 it was the scene of a great railway riot, in which twenty men were killed and twenty-nine wounded. Pop. (1874) 140,000; or, with the addition of Alleghany, 210,000.

Pittsfield, a town of Massachusetts, U.S., is situated upon a plain 1200 feet above the sea, about 150 miles W. of Boston

by salt. There are several lakes in the vicinity, which both add greatly to the beauty of the scenery and afford excellent water-power for the factories. The town contains ten churches and a fine library, and has two weekly newspapers. The principal manufactures are cotton and woollen fabrics, silk, and tacks. Pop. (1870) 11,112.

Pituitary Body, a small mass of brain-substance, situated on the base of the cerebrum or true brain, in front of the optic commissure. It consists of two vascular halves or lobes separated by fibrous tissue, varies in weight from five to ten grains, and appears to be relatively larger in the fœtus than in the adult, but is firmer in the latter state. Its function is unknown.

Pityriasis (from Gr. *pyron*, 'bran') is the term applied to one of the squamous or scaly diseases of the skin. It is a chronic inflammation of the skin, characterised by the production of numerous white scales, in irregular patches of a dull red or pinkish colour, but occasionally scarcely distinguishable from the surrounding skin. It may appear on any part of the body, and frequently in succession, and it is attended with heat, tingling, and pruritus. There are three varieties of P.—viz., *P. rubra*, *P. versicolor*, and *P. nigra*—depending chiefly upon chromogenic disorders. There are also several local varieties, named according to the site of the affection, as *P. capitis*. There is also a form of P. called *chloasma*, which is due to the presence of a parasite, *microsporon furfurans*, characterised by the presence of numerous circular brownish patches, which, however, vary in shade in different persons, and in the same person at different times, and hence its name, *P. versicolor*. The common P., or dandruff of the scalp, is the most familiar example of the disease. The proximate cause of P. is congestion of the vascular rete of the derma induced by general or local causes, such as disorder of the digestive organs, the imperfect drying of the skin and then exposing it to the sun or wind, &c. P. is more curable than the other scaly diseases, and it generally yields to the frequent use of warm baths, or to the alkaline or sulphur baths, attention being paid to the general health. The object of the treatment is to slightly astringe the vessels of the skin and soften the epidermis, and for this purpose a borax lotion or diluted white precipitate ointment should be used. The form of P. due to the presence of a fungus is best treated by the application of a saturated solution of sulphurous acid gas, or by sulphur ointment, or a lotion or ointment of bichloride of mercury. Like other parasitic diseases, it is contagious.

Piu (Ital. 'more'), a direction in music. *P. allegro*, 'faster,' *P. lento*, 'slower,' &c. *P. tosto* signifies 'rather,' as in *P. tosto allegro*, 'rather quick.'

Pius, the name of nine popes.—**P. I.**, **Saint**, born at Aquileia, was 10th Bishop of Rome (142–157 A.D.), and is believed to have suffered martyrdom.—**P. II.** (Enea Silvio de' Piccolomini), one of the most eminent scholars of his age, and one of the ablest but most intriguing of the Popes, was born at Corsignano in Tuscany, 19th October 1405, of an ancient but decayed family. His early years were spent in great poverty, in spite of which he devoted himself with the utmost zeal to the study of the ancient authors, copying them out with his own hands when unable otherwise to obtain copies. In 1431 he became secretary to Cardinal Capranica, whom he accompanied to the Council of Basel. Here he found scope for his powers of diplomacy, and became recognised as the leader of the liberal party against Pope Eugenius IV. In 1439 he became secretary to the Antipope Felix V., and in 1442, by the favour of the Emperor Friedrich III., secretary to the Chancellor Kaspar Schlick. In 1445 he went to Rome to negotiate with Eugenius, embraced his party, became his secretary, and succeeded in reconciling the pope and the emperor at the Diet of Frankfurt. He was rewarded by the new pope, Nicholas V., with the bishopric of Trieste, and Callistus III. in 1446 raised him to the Cardinalate. In 1458 he was elected Pope. P. now devoted himself to the resistance of the Turks, and laboured to effect a confederacy of Christian princes for this purpose, but died August 15, 1464, before his efforts were successful. By his merit as a pontiff he redeemed the errors of his early life. His numerous historical and geographical works were published at Helmstadt (1699–1707), and are still valuable. His *Epistole* are of great importance for the history of the time. See Voigt's *Enea Silvio de Piccolomini als Papst P. II. und sein Zeitalter* (3 vols. Berl. 1859–63).—**P. III.**

(Francesco Todeschini), nephew of P. II., was born at Siena, May 9, 1439, and elevated to the papal throne after the death of Alexander VI. September 22, 1503, but died October 18th of the same year, after a reign of 26 days.—**P. IV.** (Giovanni Angelo de' Medici) was born at Milan, March 31, 1499, and elevated to the pontificate in 1560. Of a mild disposition, and anxious to reconcile the Church, he moderated the severity of the Inquisition, and with a view to stay the progress of heresy and settle the standing questions in the Church, convoked anew the Council of Trent, November 23, 1560. Its deliberations were brought to a close and confirmed by the bull of January 26, 1564, embodying the creed usually called that of P. IV. (or the 'Tridentine Creed'), from which modern Catholicism has taken its definitive form. P. died December 9, 1565.—**P. V.** (Michele Ghislieri) was born of humble origin at Bosco, near Alessandria, in Lombardy, January 17, 1504, and entered the Dominican convent of Vigevano at the age of fourteen. Of the most austere and abstinent habits, he devoted himself entirely to the advancement of his order and confirming the Catholic faith. He was early invested with the office of Inquisitor, and was sent to Como to oppose the attempts of the Protestants to introduce their faith into Italy. In July 1551 he was summoned to Rome as commissary-general of the Inquisition by Cardinal Caraffa, who, becoming Pope under the title of Paul IV., made P., in spite of his repugnance, bishop of Sutri and Nepi in 1556, cardinal in 1557, and sometime afterwards chief inquisitor of Christendom. He was confirmed in his charge in 1560 by P. IV., whom he succeeded in the chair of St. Peter, January 7, 1566. P. now carried on a series of reforms in the public morals of Rome, and revived the Inquisition with a severity which has known no parallel in the case of any other pontiff. In 1568 he ordered the bull *In Cana Domini* to be read yearly throughout the Church, and February 25, 1570, excommunicated Elizabeth of England. P., who had long meditated a war against the Turks, now united himself with Spain and Venice, and sent a large expedition against the enemy. The battle of Lepanto (q. v.), fought October 7, 1571, destroyed the naval supremacy of the Ottoman power. P. died May 1, 1572, and was canonised by Clement XI., May 24, 1712. A volume of P.'s letters was published at Antwerp in 1640. See Agatio de Somma's *Vita di Pio Quinto* (Fr. trans. 1672), and De Falloux's *Histoire de Saint P. V.* (2 vols. Par. 1844).—**P. VI.** (Giovanni Angelo Braschi) was born at Cesena, in the Romagna, December 27, 1717. He became secretary to the Pope Benedict XIV., and held various offices under Clement XIII., being created a cardinal, April 26, 1773, by Clement XIV., whom he succeeded in the papal chair February 15, 1775. His first care was to carry out economic reforms within his states, while he did much to improve the city of Rome, draining the Pontine marsh and improving the harbour of Ancona. Soon after his accession he found himself at variance with Joseph II. of Austria, and Leopold, Duke of Tuscany, whose reforms had swept away much of the papal supremacy. P. repaired to Vienna, trusting to his influence in a personal interview, but, though received with kindness, he failed to effect anything, and was obliged to submit to the curtailment of his prerogatives by the reforming Emperor. Three years afterwards occurred the French Revolution, which caused great changes to the Papacy, imposing upon it for the future new conditions of existence. Some of the earliest acts of the constituent Assembly in France were the demolition of almost all the rights of the ancient Gallican Church, and the spoliation of its property. The remonstrances of P. were unheeded, and soon the storm fell directly upon his own head. The French Government accused him of being the enemy of France, and of instigating the murder of De Basseville, a French political agent whom the Roman populace had killed in a tumult in 1793. P. was obliged to subscribe to the treaty of Tolentino, February 19, 1797. In the same year, on the pretext of revenging the murder of General Duphot, the French Directory despatched against Rome an army under General Berthier, which entered the city February 15, 1798. P. refusing to resign his temporal sovereignty, was carried to Siena, afterwards to the Certosa of Florence, to Parma, Piacenza, Turin, and at last to Valence, on the Rhone, where he died, August 28, 1799, his malady being hastened by the ill-treatment he had received. See Ferrari, *Vita Pii VI.* (1802); Merck, *La Captivité et la Mort de Pie VI.* (1814); Artaud de Montor, *Histoire de Pie VI.* (1847).—**P. VII.** (Gregorio Barnaba Luigi Chiaramonti)

was born of a noble family at Cesena, August 14, 1744. He entered a Benedictine monastery at the age of sixteen, became bishop of Tivoli in 1782, was created cardinal by P. VI. in 1785, and transferred on the same day to the see of Imola, succeeding his patron on the papal throne March 14, 1800. Aided by Cardinal Consalvi, whom he named Secretary of State, P. restored order in his states, and carried out various reforms. Three months after his accession, the victory of Marengo laid Italy at the feet of Bonaparte, who signed a concordat with the Pope, July 15, 1801, which raised the Church from its ashes, and gave many advantages to the Pope, most of which were, however, annulled by the *Articles organiques* attached to the bull by Napoleon, and promulgated April 8, 1802, to which neither P. nor any of his successors have ever acceded. On May 18, 1804, Napoleon assumed the imperial power, and forced P. to come to Paris to crown him as Emperor. On May 16, 1805, he re-entered Rome, but before six months the troops of Napoleon appeared before the walls of Ancona. Negotiations passed between P. and the French Court, but on February 2, 1808, General Miollis entered Rome, and May 17, 1809, a decree annexed to the French Empire all the States of the Church, leaving only the city of Rome to the Pope. On June 10, P. issued a bull of excommunication against the plunderers of the holy see, without specially naming Napoleon. On the night of the 5th July the Pope's person was seized and carried to Grenoble, and in June 1812 to Fontainebleau. Here P. was confined and treated with some rigour, and was at last compelled to sign a new concordat, yielding up the Papal States. The fall of Napoleon restored him to freedom, and May 24, 1814, he re-entered Rome. P. at once began to repair the evils created by his long absence. Naturally he did not love either the wild democracy of the Revolution or the military despotism to which it gave birth. He condemned Freemasonry, anathematised the Carbonari, encouraged missions, and restored the Jesuits. The Vienna Congress restored to the Church much of what it had lost, and the Governments of Naples, Prussia, and Wurtemberg concluded concordats with the Court of Rome. P., who had borne all his sufferings with Christian resignation, died from the effects of a fall in his chamber, August 20, 1823. See Cohen's *Paris Hist. et Polit. sur Pie VII.*, 1823; A. de Beauchamp's *Hist. des Malheurs et de la Captivité de Pie VII.*, 1814; Artaud de Montor, *Histoire de Pie VII.* (3 vols. 1836).—**P. VIII.** (Francesco Xavier Castiglione) was born at Cingoli, in the March of Ancona, November 20, 1761. In 1800 he became Bishop of Monte-Alto, Cardinal in 1816, and Pope March 31, 1829. He died November 30, 1830, after giving promise of illiberality in his views and severity in his punishments.—**P. IX.** (Giovanni Maria Mastai Ferretti, Count) was born at Sinigaglia, May 13, 1792. He was the son of Count Jerome Mastai Ferretti, the head of a Lombard family which had acquired nobility in the 17th c. from the Duke of Parma, and the Countess Caterina (*née* Solezzi), while he had an uncle who was Bishop of Pesaro. He entered the College of the Padri Scolopi at Volterra in 1803. Originally intended for the military profession, he was prevented from pursuing this career by epileptic fits, and in 1810 proceeded to Rome to study theology under Giuseppe Graziosi. He resided with his uncle, Paolino Mastai Ferretti, who was a prelate of the Papal Court and Canon of the Vatican. In 1814 he was presented to Pope P. VII., who was returning from his captivity in France. Young Ferretti at first devoted himself to the care of a hospice where young orphans were sheltered and taught, known from its founder, Giovanni Borgi, by the name of Tata Giovanni. Ordained a priest in 1819, he accompanied Monsignor Muzi in a mission to Chili, leaving Rome July 5, 1823. He remained in Chili for two years, and on his return to Rome was made a prelate (June 25, 1825). He was now appointed by Leo XII. president of the hospital of St. Michele on the Ripa Grande, archbishop of Spoleto in 1828, and transferred by Gregory XVI. to the bishopric of Imola, September 17, 1832. Here he carried out many liberal reforms, and did much to diffuse learning more widely within his diocese. Being sent on a mission to Naples at the time when cholera was raging in that city, he disposed of his plate and equipages for the relief of the dying and starving poor. In 1840 he became a cardinal, and on the death of Pope Gregory XVI. was elected Pope, June 16, 1846, by thirty-six votes out of the fifty present, avowedly the leader of the reform-

ing party, as opposed to the constitutional party, headed by Cardinal Lambruschini. Twelve hours after his election, Cardinal Gayenack, Archbishop of Milan, reached Rome with instructions from Austria to veto the election of the bishop of Imola, which were, however, too late to be effectual. The new Pope took the title of P. IX., and inaugurated his reign with a number of promising liberal measures, beginning on the 16th July a general amnesty releasing all prisoners (to the number of 2000), recalling all exiles, and restoring to them their civil rights. At the same time he granted 300 crowns yearly to the relief of poor Jews, and removed from them most of their disabilities, permitting them to reside in any part of the city. In August 1846 he issued a commission for the making of railways in his dominions, and soon afterwards granted a concession to an Englishman for a gas manufactory, and took an active interest in agriculture and the reclaiming of the deserted Campagna. These measures brought him the utmost popularity, and in the commencement of his reign he was the idol of all classes. Mazzini reproached him with the words '*Abbiate fede Santo Padre, and you will*,' and Carlyle declared that 'the old chimera was rejuvenated!' In June 1847 he made the liberal Antonelli a cardinal, and soon after Minister of Finance. On March 4, 1848, P. published a constitution, in which he appointed two chambers—the first of members nominated by the Pope, the second, formed of representatives chosen by the electoral districts, one to 30,000 voters. Notwithstanding these reforms, a revolutionary feeling spread through Rome, fostered by the political refugees to whom his amnesty had opened the city, and on November 15, 1848, Count Rossi, the Pope's first Minister, was assassinated. From this time P. changed his rôle, satisfied that his liberal measures had failed to attach the populace. Finding that his personal safety was in danger, he fled from Rome on the 24th November 1848, to Gaeta, where he put himself under the protection of the King of Naples. At Rome a republic was proclaimed, at the head of which was Giuseppe Mazzini, who, with Armellini and Saffi, conducted the government with great prudence, until General Oudinot, at the head of a French expedition, after a siege of thirty days, took Rome (July 2, 1849), and invited the Pope to return. He entered his capital April 12, 1850, after an absence of seventeen months. His government was from this time the complete reverse of what it had been at first, and swayed by Antonelli and protected by the resident French army, he refused to make any compromise with the Liberals, and preserved until the loss of his power an obstinate and unreasoning Conservatism. He now devoted himself, as if in contrast with his former political activity, to schemes of church advancement, while he canonised saints, lavished indulgences, and at last proceeded to propound new dogmas, and to pronounce judgment on controversies which had been left unsettled by the wisdom of the ages. In 1850 he re-established the Catholic hierarchy in England, and in 1854 issued a decree propounding the doctrine of the Immaculate Conception (q. v.). In 1864 he published the syllabus of errors, and June 29, 1868, a bull for the convocation of an Ecumenical Council, whose opening was fixed for the 8th December 1869. In its fourth session, July 18, 1870, the dogma of the Papal Infallibility was promulgated. After the final withdrawal of the French troops in 1870, the inhabitants of the papal territory began to demand incorporation with the Italian kingdom, and on the 12th September General Cadorna crossed the frontiers. At first it was expected that P. would quit Rome, but after consideration he decided to remain. The result of the plebiscite on the 2d October was 40,805 for, and 46 against union with Italy. The Italian Government voted the Pope a pension of £129,000 annually, and on the 31st December 1870, King Victor Emmanuel entered the Quirinal. Since 1870 P. remained in Rome, but he unceasingly kept alive the memory of his wrongs by numberless allocutions and encyclicals, while by the active intrigues of his court he continued to harass the Italian Government and to scheme at every court in Europe, which was the chief cause of the dissension between the President and the French Republic in 1877. In November 1872, P. issued an encyclical letter for Germany, in which he called the Old Catholics (q. v.) 'wretched sons of perdition.' June 25, 1875, was the fiftieth anniversary of his consecration as a bishop, and his episcopal jubilee, to which many pilgrims flocked from all countries with rich offerings, was celebrated with great rejoicings. He died on the 7th February 1903 at the age of eighty-six. His reign can scarcely be reckoned at, but as a

failure in its determined opposition to the spirit of the age, but the career of his public life were somewhat redeemed by the career of his private character. His sending his benediction to the dying king of Italy was a fine example of Christian forgiveness. It was the act of P. to hold the helm of the Church in the most troubled times of the Papacy, and it was his misfortune, not his fault, that he had not the wisdom or ability to steer her safely through the storm. In the annals of his 257 predecessors there have been few more eventful pontificates, though many greater Popes. See T. A. Trollope's *Life of P.* (2 vols. Lond. 1877), and that by J. F. Maguire, M.F., and Monsignore Gasparini (Lond. 1878).

Piv or Joint, the name given to those joints of the bodies of higher animals which move round a pivot or central fixed axis. They are also named 'rotary joints.' The articulation between the head and neck, or the movements of the forearm, by means of the radius passing round the ulna and lower end of the humerus, are examples. In the neck the *pivot* is formed by the *odontoid process of the axis* (or second vertebra of the neck), around which the head, together with the *atlas* (or first vertebra) turns.

Pizarro, Francisco, illegitimate son of Gonzalo Pizarro, a Spanish colonel of infantry, was born at Truxillo, in Estramadura, about 1471. Taught neither to read nor to write, and left to pick up a living as a swineherd, he ran away at last from his employer, and at Seville embarked with many other adventurers for the New World. He served under Alonzo de Ojeda in Hayti, and was appointed by him to command the colony. Later he was associated with Balboa at Darien, and with Pedro Arias, governor of Panama. He formed plans for a voyage of discovery with a wealthy priest and a daring soldier, named respectively Hernando de Luque and Diego de Almagro. In November 1524 he set sail from Panama with 100 men, Almagro following in another vessel, but they only went as far S. as Quemada Point. In March 1526 they again started, and after incredible hardships finally discovered the long-fabled Peru, and partly explored the country. In 1528 P. returned to Spain, and there exhibited specimens of gold and silver and cloth obtained from the Peruvians. He was invested by Karl V. with the full rights of his discovery, and was named captain-general of the province, with a salary of 725,000 maravedis. On his return to Peru with a small, well-equipped force of 110 foot soldiers and 67 cavalry, he found a civil war raging between Huascar, the legitimate ruler, and his half-brother Atahualpa (q. v.). Professing to espouse the cause of the latter, he got access to the interior of the country. After having captured the unsuspecting chief, and exacted from him an immense ransom, he burned him at the stake. Shortly after this a quarrel between P. and Almagro resulted in a civil war, which ended in the death of the latter, by whose followers P. was assassinated, 26th June 1541. He married the Inca's daughter, and his descendants, preserving the title of Marquis de la Conquista, are still to be found at Truxillo. P. was lucky rather than skilful. Rash, treacherous, cruel, he is only credited with the virtues of brute courage and perseverance.—**Gonzalo P.**, youngest brother of the preceding by the same father but another mother, was born at Truxillo, 1506. Early in life he crossed to Peru, and soon became the first lance in the country. He was the best guerilla chief of his time, but no general. In 1540 Gonzalo was appointed governor of Quito by his brother, and led across the Andes an expedition which resulted in the discovery (though not by him) of the Amazon's source. After the murder of his brother, Gonzalo became master of Peru by defeating Blasco Nuñez in a pitched battle at Quito, 1546. But the mastery did not continue long. Pedro de la Gasca, at the head of the Spanish royalist forces, defeated and beheaded him in the following year. See Prescott's *History of the Conquest of Peru* (2 vols. 1847), and Helps' *Life of P.* (1869).

Pizzicato (Ital. 'pinched'), a direction in music for the violin, meaning that the strings are to be plucked with the finger. This style of playing often produces a pretty, piquant, guitar-like effect, and is very useful in accompaniments. The direction 'col arco' or 'arco' indicates that the use of the bow is to be resumed.

Pizzo, a district of S. Italy, province of Catanzaro, on a sandstone rock above the Gulf of Sta. Eufemia, 25 miles

W.S.W. of Catanzaro. It has a ruined castle, where Joachim Murat, King of Naples, was shot, 12th October 1814. There is some trade, and an important tunny fishery. Pop. (1874) 8,100.

Placenta, or afterbirth, the structure, developed to its fullest and most typical extent in *Mammalia*, through which communication is maintained between the mother and the unborn young. Through the P. respiration, excretion, circulation, and other processes in the young animal are maintained. Traces of this structure are visible in lower forms of animal life than mammals; e.g., in sharks and dogfishes. In these, however, the so-called P. is not developed from the true layers investing the embryo, but from a particular sac or vesicle devoted to the nutrition of the young form, and known as the *umbilical vesicle*. Its mode of origin in these lower vertebrates is therefore essentially different from that which it exhibits in mammalia. All mammals, however, do not possess a P. The two lowest orders of mammalia—the *Monotremata* (q. v.) and *Marsupialia* (q. v.)—represented by the ornithorhynchus, kangaroo, opossum, and allied forms, are destitute of it. These mammals are hence called *Implacentalia* or *Non-placental* mammals, in contradistinction to the other orders which are grouped together under the name of the *Placentalia*. To understand the structure of the P., and its modifications in the various groups of mammalia, it is necessary in the first instance to glance at its relations and development in the human subject. The inner lining or *mucous membrane of the uterus* or *womb* undergoes a marked development after the occurrence of impregnation. It becomes greatly thickened, and its upper layer or surface forms what is known as the *membrana decidua*. This soon exhibits a division into three layers—the *decidua vera*, which lines the uterus; the *decidua reflexa*, which invests the young animal; and the *decidua serotina*, or part which is brought in connection with certain processes or *villi* of the *chorion*, i.e., the outer covering of the foetus or embryo itself. The villi of the chorion, therefore, come to be lodged in certain depressions or *crypts*, as they are named, in the *decidua* of the uterus, so that in this way the fetal and maternal structures fuse and interlace. The limited portion of the chorion which is thus connected with the lining membrane of the uterus marks the site of the future P. The deeper portion of the mucous membrane of the uterus is hollowed out to form *sinuses*, or *spaces* which on the one hand open into the arteries, and on the other into the veins of the womb. The villi, or processes of the chorion, in due time grow into these sinuses, and push the thin walls of these cavities before them as they grow. The result of this is that the villi are soaked in the maternal blood which is circulating through the uterine sinuses; but it must be carefully noted that there is no direct or actual passage of the blood of the mother into the embryo. All that is contrived in this arrangement is that the blood of the mother may interchange products, by diffusion, with the blood of the foetus; these products passing readily through the thin wall of the villi and being interchanged for other products obtained from the maternal blood. That there is an actual interchange of products between the mother and the foetus, notwithstanding the absence of any direct communication between the two circulations, is evident from the observations of Drs. Harvey, Savory, and Hutchinson; poisonous matters injected into the body of foetal animals being found to pass readily and freely into the body of the mother, and even to cause death by passing into the maternal circulation through that of the foetus.

In the human subject, therefore, the P. consists of a *maternal* and *fetal* portion. It is *discoid* or cake-like in shape, from the limited area over which it is developed on the uterine walls. At birth the greater part of the P. is thrown off. It becomes detached from the walls of the uterus by the so-called *after-pains* of childbirth, together with the *decidua vera*, *decidua reflexa*, and a part of the *decidua serotina*. The remaining portion of the latter membrane becomes absorbed, or may be thrown off along with the uterine discharges which persist for some time after parturition. In the human subject the P. is said to be *discoid* in shape, and it is also termed *deciduous*, because it is cast off wholly or in greater part at birth.

All mammals, however, do not exhibit the human type or structure of P., nor are the placental structures always cast off at birth in the manner just described. As an example of an entirely different type of P., that of the pig may be selected. In

this animal the mucous lining of the uterus enlarges during the progress of utero-gestation, and the villi of the chorion combine and unite with the uterine structures as in man. But there is a notable difference in the manner in which the P. is developed in the pig; for that structure is not limited to one region of the chorion and uterus, but is developed from all parts of the chorion, save at its extremities or poles. Moreover, at birth the maternal structures are not thrown off to any appreciable extent. The villi of the chorion representing foetal structures are simply withdrawn from the uterine depressions in which they are lodged as the fingers might be drawn out of a glove. Hence the placentation in the pig is said to be *non-deciduate*, as opposed to that of man and other animals in which both foetal and maternal structures are thrown off.

All the *Primates* (man and apes or *Quadrumania*)—save the lemurs—possess a P., which is discoid in shape, and which is also deciduate. In the bats (*Cheiroptera*), *Rodentia*, and *Insectivora* (moles, shrews, and hedgehogs), the P. conforms to the human type. The *Carnivora* also possess a deciduate P., but the form of the organ differs from that of man in being *zonary*—that is, the P. has the form of a zone or girdle enveloping the middle portion of the chorion, but undeveloped at the poles. All *Ungulate* mammals (pigs, deer, antelopes, sheep, ox, hippopotamus, rhinoceros, tapir, horse, camel, &c.) possess a *non-deciduate* P., and in this respect the *Cetacea*, or whales and dolphins, agree with them. The placentation of the order *Sirenia* (q. v.), including the Manatees (q. v.) or sea-cows and dugongs, has not been determined; but in all probability these animals will be found to agree with the whales. Among mammals which have a *non-deciduate* P. there are variations in the form and disposition of the organ. The pig, horse, camel, and cetaceans have the villi of the chorion scattered irregularly over the surface of that membrane. Hence the P. is termed *diffuse* in these animals. In the *Ruminants*, on the other hand, the villi are disposed in groups named *cotyledons*, and these may be received (as in the sheep) into cup-like depressions of the uterine walls; or (as in the cow) the villi may be concave, and may fit upon convexities of the uterine surface. The ruminant P. is therefore named *cotyledonary*, in opposition to the term 'diffuse.' The elephants (*Proboscidea*) have a *zonary* P., and so have the curious little genus *Hyrax* (q. v.). Huxley believes that the P. in both of the latter cases is truly deciduate. The elephants, in this view, become nearly related to the rodents; while *hyrax* remains as the type of a distinct order of mammals. The order *Edentata* presents many singularities of structure of the P., and would appear to include within its limits representatives of nearly all the types of the other groups. Thus, in *Manis*, the P. is diffuse and *non-deciduate*; in the sloth it is not *cotyledonary*, as was formerly believed, but a discoid and deciduate structure allied to that of the primates. *Orycteropus* has a *discoid* and *deciduate* P., and that of the armadillos is also said to be discoid. Professor Owen, speaking of the P. of the latter animals, says it is a single thin oblong disc, composed of foetal and maternal structures. In the lemurs, which are mammals regarded as representing the lowest members of the *Quadrumanian* order, the P. appears to differ in the most remarkable manner from that of other Primates. Turner, speaking of the P. of this order, says, 'As the P. in the lemurs has the arrangement and structure of a diffuse P., it is presumably as non-deciduate as that of the other animals which possess the same form of P.; for in it, as in them, the foetal P. can be separated from the maternal without carrying away a portion of the uterine mucous membrane.'

Diseases of P.—The P. is liable to various diseases, the more important of which are apoplexy; fatty, cartilaginous, and calcareous degeneration; placatitis; general oedema; and atrophy. Apoplexy of the P. is caused by effusion of blood from ruptured vessels into the parenchyma of the organ, exactly as takes place in the lung. In fatty degeneration, the fatty molecules are either thrown out primarily as inflammatory exudations, or are formed secondarily from inflammatory products, which degenerate into fatty particles. Placatitis, or inflammation of the P., may terminate in morbid adhesions, hepatization, induration, and abscess; but the morbid action is generally confined to a limited portion of the P., and extends from the maternal towards the foetal surface. In general oedema, the tissues are soft, swollen, pale, and infiltrated with serum. D. of the P. are always dangerous, and often fatal to

the fetus; and in many of them there is a tendency to abort in subsequent pregnancies. As a general rule, the uterus is excited to active contraction by the morbid products, and abortion is the result; but in some cases the diseased vitality of the P. is maintained, while the embryo becomes shrivelled and atrophied, and may be retained till the last period of gestation.

Placenta is the part of the inside of the ovary to which the oviducts are attached, sometimes a mass solid or line on the inner surface, often more or less thickened or raised. Placentas are *axile* when the oviducts are attached to the axis or centre, that is, in plurilocular ovaries when they are attached to the inner angle of each cell; in unilocular simple ovaries when the oviducts are attached to the side of the ovary nearest to the axis; in unilocular compound ovaries when attached to a central protuberance, column, or axis rising up from the base of the cavity. If this column does not reach the top of the cavity, the P. is said to be *free* and *central*. They are *parietal* when the oviducts are attached to the inner surface of the cavity of a one-celled compound ovary. Parietal placentas are usually slightly thickened or raised lines, sometimes broad surfaces nearly covering the inner surface of the cavity, sometimes projecting far into the cavity, and constituting partial dissepiments, but never cohering in the centre. (Bentham.) See PISTIL.

Placentalia and Placental Mammalia. See PLACENTA.

Placentalia. See PIACENZA.

Placodus, an extinct genus of Vertebrate animals, the remains of which occur in rocks of *Triassic* age. It was formerly regarded as a fossil fish of the *Ganoid* kind, but is now held to be reptilian, and is included in modern systems of classification in the order *Sauropsid*, a group to which the *Placodonts* and other extinct reptiles belong. In P. the teeth occupied distinct sockets. They were of rounded form, and resembled the flat plate-like teeth found in some rays and sharks, and which are adapted for crushing the hard shells of crustaceans, &c. A double series of teeth were developed in the upper jaw of the P.; only a single row in the lower jaw.

Placogonoid Fishes, or Placogonoides, a division of *Ganoid* (q. v.) fishes, represented by the Sturgeon (q. v.), in which the skeleton is imperfectly developed; the body being incompletely covered with ganoid scales or plates often united by suture. The fossil genera *Cephalaspis*, *Pterichthys*, *Pteraspis*, &c., belonged to this section of the ganoid order.

Placoid Fishes, one of the subdivisions of the class *Pisces* or fishes proposed by Agassiz, and founded upon the characters of the scales. Placoid scales consist of small bony plates, which may bear a central spine, and are well seen in sharks, rays, and dog-fishes—these belonging to the order *Elasmobranchii* (q. v.). They do not completely invest the bodies of fishes, but are scattered in an irregular manner over the skin surface. Placoid scales occur in a fossil state, along with fossil fin spines or *ichthyodurites*.

Pla'gal, in music (Gr. *plagios*, 'oblique'), a term applied to the four Church modes formed by St. Gregory from the 'authentic modes' of St. Ambrose, by taking the fourth below the final as the new keynote of a scale extending to the fifth above. See

GREGORIAN CHANT. P. melodies have their principal notes between the fifth of the key and its octave or twelfth. P. cadences (sometimes called Church cadences, being much used in sacred composition) are those in which a subdominant chord precedes the final tonic chord.

Plagios'tomi (Gr. 'transverse-mouthed'), a sub-order of *Elasmobranchiate* fishes, including the sharks, dogfishes, and rays. The mouth is placed crosswise on the under surface of the head. The skull has no distinct cranial bones, and is of cartilaginous structure, and the vertebral bodies are usually cartilaginous, but the other parts of the skeleton are cartilaginous. The scales are

Plasma (q. v.), and the gills are sac-like structures opening outwardly by *branchial slits*, water being also admitted to the gills by means of tubes opening in *spiracles* on the top of the head. There is no air-breathing.

Plague (*q. v.*), from the Gr. *πληγή*, 'a stroke,' i. e., inflicted by the pestilence, derivation indicating the ancient belief as to the source of the P. is a febrile disease, characterised by tubercles or swellings of the lymphatic glands, by carbuncles and petechiæ. P. prevails at certain times and places epidemically, but its true home is in the regions bordering upon the eastern extremity of the Mediterranean and its tributaries. At different periods of the 13th, 16th, and 17th centuries it occasionally visited Western Europe, and was well known in Italy, France, Germany, and England, London and Paris having suffered greatly from it in former times. The last remarkable epidemic of P. was in 1720, when Marseille lost nearly one half of its population. In later times it has been limited chiefly to Egypt, Syria, Arabia, Greece, and European Turkey; occasionally extending northward into Russia, and westward as far as Malta. In 1844, P. became apparently extinct; but it re-appeared in Western Arabia in 1853; in the province of Bengaz, Tripoli, in 1858-59; in the extreme N.W. of Persia in 1863; among the Arabs of the right bank of the lower Euphrates in 1867; in Persian Kurdistan in 1871, and among the Afij Arabs on the lower Euphrates in 1873-74. Since the latter date, P. has prevailed epidemically in the regions adjoining the lower Euphrates till the close of 1877, the number of deaths officially recorded at Bagdad from January till June 1877 having been 1672.

The promontory symptoms of P. are chilliness, weariness, languor or debility, precordial uneasiness, occasionally nausea and vomiting, headache, vertigo, a hot and dry skin, and a frequent pulse. These conditions are soon followed by the peculiar symptoms of P.; darting pains are felt in the groins, arm-pits, or other parts of the body, which are soon followed by enlargements of the lymphatic glands, or by inflammation of the subcutaneous tissue, constituting carbuncles. As the disease advances, the swellings increase; the tongue becomes furred, often dry, brown or blackish, and fissured, while a dark sordes collects upon the gums and lips; and there is often great thirst and an internal sensation of burning heat. The bowels, which are at first constipated, become relaxed, the stools being dark, offensive, and sometimes bloody; and the urine is generally scanty, turbid, yellowish or blackish, and tinged with blood. The general strength is greatly prostrated; the patient has a staggering gait, and attacks approaching to syncope are not uncommon. The power of the will is impaired, the intellect is confused, and delirium or coma may supervene. There are usually remissions in the morning and evening, and exacerbations during the middle of the day and night, the morning remissions and nocturnal exacerbations being commonly the greatest. Buboes may appear at the commencement of the disease, or after one or more days, or not until near the close. Carbuncles usually make their appearance later than the buboes, and may occur on any part of the body. Petechiæ, or purplish spots like flea-bites, which usually become livid as the disease advances, occur only in bad cases; and sometimes along with these spots there are vesicles, or irregular purplish or livid patches like bruises.

Great difference of opinion has existed, and still exists, as to the cause of P. Some maintain that it is propagated by a peculiar contagium; others, while admitting its contagious nature, affirm that it often occurs endemically or epidemically; while others again assert that it originates exclusively either in local causes or epidemic influences. The evidence in support of the contagious nature or communicability of P. is undoubted, and it is extremely probable, though not yet demonstrated, that it depends upon the growth and multiplication of specific germs. Some have conjectured that P. is generated *de novo* from the filthy accumulations and excretions of a crowded and uncleanly population; but such exist elsewhere, and apparently under the same circumstances, without producing the effect. P. is an exceedingly fatal disease.

With respect to treatment, little can be done. There is no specific for P., and the symptoms can only be met by palliative treatment. P. is essentially a filth disease, its local habitat being in places where sanitary arrangements and personal cleanliness are ignored. That this is the case is evident from the fact that

European residents, especially English, in the infected cities of the Levant, enjoy a comparative immunity from P. See Hecker's *Epidemics of the Middle Ages* (1844, published by the Sydenham Society); *Reports on Leprosy*, P. by Mr. Netten Radcliffe, in *Medical Officers' Report to Local Government Board* (New Series, No. vi.), and Supplement to the Sixth Annual Report of the Local Government Board for 1876 (Lond. 1878).

Plagues of Egypt were ten calamities brought upon the country by Moses (q. v.), with the purpose of compelling Pharaoh to let the Hebrews leave Egypt and set out for Canaan. Opinion regarding these P. (enumerated Exod. vii.-xii.) has been somewhat modified of late years. Travellers have discovered that they correspond in a remarkable degree with natural phenomena which occur in the country: e.g., the Nile at certain seasons has a blood-red appearance; extraordinary numbers of frogs sometimes make their appearance; the country is sometimes visited by a murrain among the cattle, or a plague of locusts; a species of stinging fly and a painful skin disease occasionally afflicts man and beast; and a wind from the desert at times raises such clouds of sand as to obscure the air for days. Accordingly, while the Rationalistic school consider the P. myths have arisen out of the natural phenomena, the ablest conservative critics explain the first nine as 'having become signs and wonders through their vast excess above the natural measure of such natural occurrences and their supernatural accumulation.' But by many the greatest difficulty is felt to be the implied idea that the displeasure of God is expressed by physical disaster, an idea which, though universally held in ancient times, is now regarded by educated people with considerable suspicion. Again, perhaps the greatest difficulty encountered by rationalising critics is how to account for what the magicians of Egypt are said to have done. According to the Christian Fathers they did it by the help of demons, or according to the latest theory it was mere jugglery. But that the writer meant that the magicians did the same things as Moses in certain of the wonders, is just as clear to a candid reader as that he understood the P. to be miracles. And hence the real difficulty here is the implied belief, which was also universally held in ancient times, that magicians could do things which far surpassed the power of ordinary mortals. See *The Speaker's Commentary* (vol. ii. Lond. 1872), *The Bible for Young People*, by Oort, Hooykaas, and Kuonen (vol. ii. Eng. trans. 1875).

Plaice (*Platessa vulgaris*, or *Pleuronectes platessa*), a species of *Pleuronectide* or flat-fish, common on the British coasts. It attains a weight of from 1 or 2 to 8 or even 15 lbs. Its colour is a dark brown marked with red spots. The P. is caught in large quantities by nets, but may also be captured by line; a favourite bait being lobworm. It ascends rivers to spawn.

Plaid (Gael. *plaid*, 'a blanket,' contracted from *peallaid*, 'a sheep-skin'), a garment of chequered woollen cloth worn loosely or belted round the body as an outer covering. It forms a characteristic part of the costume of the Scottish Highlanders, who fasten it with a brooch at the shoulder.

Plain (Lat. *planus*), an extensive tract of level country, distinguished on account of lesser elevation from plateaux or Tablelands (q. v.). Examples in Europe are the plains of N. Germany, of Hungary, and of Russia to the E. of the Carpathians. The steppes of Eastern Europe and Asia, the deserts of Africa and Arabia, the prairies and savannahs of N. America, and the S. American llanos, pampas, and silvas, are all true plains, differing only in name and characteristics.

Plain-Song, or *Canto-Fermo*, a term originally applied to ecclesiastical chants in which the notes were of equal value and all corresponded to the white keys of the pianoforte. They were expressed on a staff of four lines. P.-S. has remained unaltered since the days of Gregory the Great. Many fine specimens of counterpoint on the plain chant, where the chant was preserved in one of the parts, and various other parts were arranged as imitations, canons, fugues, &c., were produced in Italy in the 16th c. See Stainer and Barrett's *Dictionary of Musical Terms* (1876).

Plaint (in English law) is the first process in an inferior court; or in a superior court is a complaint against the defendant, and for which the plaintiff obtains the Queen's writ. In

the county courts it describes the parties, the sum claimed, and the cause or motive of the action.

Plain'tiff (in English law) is the term denoting the person who brings a civil action against another, who is termed the *Defendant*. In Scotland the P. is called the *Pursuer*.

Plaiting, or **Platting**, is the art of interlacing flexible materials in order to produce a basket, mat, or other article. This art, which is allied to weaving, only differing from it in the fact that the fibres employed are not previously *spun*, has been universally practised from the most remote ages to the present time. Many degraded races, ignorant of the art of weaving, are very expert in P., while in civilised communities it is the foundation of the straw-plait and basket-making industries.

Plan (in Architecture) is properly the horizontal section of a building showing the disposition of the ground plot and of the upper floors. In common discourse the term P. is often used for any kind of architectural drawing.

Planaria, a genus of *Scolecida* (q. v.), belonging to the *Platyelmia* or 'flat worms,' and forming the type of the group *Planarida*. *P. larva* and *P. lactea* are two familiar species. These animals occur in mud and in damp earth, or on aquatic plants. They present the appearance of small flattened bodies, measuring from half an inch in length. The skin is provided with cilia, and a proboscis may exist. A distinct mouth and digestive system are developed, and the intestine may be straight or branched, and is never provided with an anus or outlet. The 'water-vascular system' opens externally by one or more apertures. The P. are hermaphrodite, and reproduction may take place by *fission* and by *budding*, as well as sexually.

Planché, James Robinson, an English dramatist and archaeologist of French descent, was born in London, February 27, 1796. His first burlesque, *Amorosa, King of Little Britain*, was produced at Drury Lane in 1818. He has written more than two hundred pieces for the stage, including the libretti of a number of operas (among which is Weber's *Oberon*). He may be said to be the father of modern burlesque, though his extravaganzas, *The Fair One with the Golden Locks*, &c., instinct with grace, taste, and refinement, are entirely free from the vulgarities which disfigure many of the works of his successors. He designed the costumes for Mr. Charles Kemble's Shakesperian revivals. P. was a Fellow of the Society of Antiquaries (1830-52); was appointed *Rouge Croix Pursuivant of Arms* (1854), and *Somerset Herald* (1866). He has published *Lays and Legends of the Rhine* (1826); *Descent of the Danube* (1827); *History of British Costume* (1834); *The Pursuivant at Arms: A Treatise on Heraldry* (1852); *King Nut-Cracker: A Fairy Tale* (1853); *A Translation of the Fairy Tales of the Countess D'Aubigny* (1855); *A Corner of Kent* (1864); *Recollections and Reflections of J. R. P.* (2 vols. 1872); *The Conqueror and his Companions* (2 vols. 1874), and a great number of songs and essays. His recent contributions to *Mirth* (1877) show that the genial veteran still retains his youthfulness of spirit.

Plane (in Geometry) may be defined as the surface swept out by a straight line moving parallel to itself along a given straight line. Every line which can be drawn in it is perpendicular to a definite direction; and a straight line drawn from a point in the P. in this direction is called the normal to the P. Parallel planes have the same normal. The Cartesian equation to a P. referred to rectangular axes is—

$$\frac{x}{a} + \frac{y}{b} + \frac{z}{c} = 1.$$

This intersects the P. xy ($z = 0$) in the line—

$$\frac{x}{a} + \frac{y}{b} = 1,$$

from which it is evident that a , b , and c are the intercepts on the axes made by the P. The intersection of two planes is always a straight line; and, unless their normals are coplanar, three planes intersect in a point. This last is equivalent to the algebraic statement that three equations between three unknown quantities are necessary and in general sufficient to determine these.

Plane and Planing Machine. A P. is an implement for smoothing the surface of wood or any other material, such as cast metal. It acts on level, even surfaces alone; other tools,

such as the lathe, are employed for round or curvilinear work. An ordinary P. is a well-known hand-tool, used by joiners, cabinet-makers, and other wood-workers. The body of a common P. is usually made of beech, but sometimes for fine work boxwood is employed. The under surface of the P., which is moved along the wood operated on, must itself be a true plane, and through a slit or hole in it projects the chisel-edged P.-iron, which is the essential cutting-tool of the P. What is termed a double P.-iron is the common form employed, it having attached to the cutting-chisel by a screw, a movable plate of metal of the same breadth as the chisel itself, and which can be moved to or from the cutting-edge, according as a fine or deep bite or shaving is desired. The cutting edge can correspondingly be made to project more or less beyond the plane surface, according to the nature of the work, and the iron is held in its place by a wooden wedge driven tightly against it. In some planes the iron is fixed and its bite regulated by an arrangement of screws. The pitch or angle of inclination of the P.-iron varies in different planes, being more variable in those used for hard wood than in such as are employed for dressing soft wood. The variety of hand-planes for wood is very considerable, special forms of P.-surface and iron being required for groovings, mouldings, beads, &c.; fillisters, rabbets, hollows, rounds, and ploughs are well-known forms of planes.

Planing machines are now largely employed in the timber-growing countries for preparing and dressing wood in the forms in which it is extensively used, such as grooved and tongued flooring, mouldings, &c. These planing machines embrace two principal forms—(1) carriage machines, in which heavy timber is dressed by traversing cutters operating on one surface; (2) parallel machines, in which the wood is reduced to parallel dimensions on all sides by means of fixed opposite cutters, or between fixed cutters and a stationary bed or gauge. The second form of machine is employed for dressing boards, flooring, mouldings, &c. In the manufacture of implements of precision and fine machinery, true planes are of the most essential consequence, and the surface plates made by Sir Joseph Whitworth & Co. of Manchester, which are the nearest approximation to perfect planes ever yet obtained, have been of the highest value in advanced mechanical engineering. A machine to communicate a plane surface to any material must itself move in a plane surface, and the essential feature of machine planes for metal consists in a rigidly fixed cutting-chisel, against which the metal to be abraded is moved backward and forward along a bed which is a true plane.

Plan'et is the generic name for all cosmical bodies which like the earth revolve round the sun. Ordinarily, however, it is restricted to the larger and more important of these bodies, excluding the planetoids, comets, and meteorites. The name is derived from the Greek *planētēs*, 'a wanderer,' a term suggested by the apparently irregular motions by which planets are distinguishable from the fixed stars. The fixed stars always retain the same position relatively to each other. The sun and moon appear to move through them in an approximately regular manner, the former taking a year and the latter a month to perform the complete cycle. The planets, however, for long baffled every attempt to reduce their motions to a definite law; and as long as they were not understood, there was no hope for the even more eccentric comet. The motion of a P. among the stars is now direct, like that of the sun and moon, and now retrograde; while at times the P. comes to a standstill altogether. When the true system of the universe was finally recognised, these peculiarities of motion were at once seen to be necessary consequences of the conditions.

To the ancients five planets were known, viz. Mercury, Venus, Mars, Jupiter, and Saturn. Copernicus added the Earth when he fixed the centre of the universe in the sun. The elder Herschel detected a seventh, Uranus; the analysis of Leverrier and Adams gave us an eighth, Neptune; and the discovery of the first asteroid or planetoid by Piazzi on January 1, 1801, was a fitting inauguration of a century so rich in astronomical research. The empirical laws of Kepler—that planets move in ellipses round the sun which occupies a focus; that the radius vector of a P. describes equal areas in equal times; and that the squares of the periodic times of any two planets are as the cubes of their mean distances—led Newton to the demonstration of the law of gravitation. The direct dyna-

mical consequences of this law showed that Kepler's laws were true as a first approximation only, and that necessary perturbations produced deviations which could not be neglected in a complete planetary theory. Newton's work was ably supplemented by the brilliant researches of the great French astronomers Laplace and Lagrange. The latter was led by analysis to the enunciation of two remarkable theorems, which guarantee the stability of our system. These are:—'If the mass of every P. is multiplied by the square root of the major axis of its orbit, and the product by the square of the tangent of its inclination to a fixed plane, the sum of all these products will be constant under the influence of their mutual attractions;' and 'if the mass of each P. is multiplied by the square root of the axis of its orbit, and the product by the square of its eccentricity, the sum of all is invariable.' For the elements and other details, see the special articles upon the various planets. See also PERTURBATIONS.

Planets. The name generally given now to the small planets which lie between Mars and Jupiter, and which were formerly known as Asteroids (q. v.). Yearly their numbers are being added to, and at present there seems to be no limit to the discovery of new ones. There are now (March 1878) 185 P.

Platanus (*Platanus*) is the sole genus of *Platanaceæ*, consisting of large trees with flaking bark, palmatifid leaves, monœcious flowers collected into unisexual globose pendulous heads, intermingled with acule-like bracteoles, each carpel producing a small one-seeded nut. It is generally considered to consist of five or six species, natives of the northern hemisphere; but some botanists incline to the idea that it comprises only one widespread and variable species. *P. orientalis*—the Eastern P.—indigenous to Greece, Armenia, and Persia, under favourable circumstances forms a majestic tree, with wide-spreading branches, and attaining a height of 70 to 90 feet. It has long been a favourite ornamental shade tree for lining roads and for street planting. Even in larger towns, such as London, it grows vigorously, resisting the smoke better perhaps than any other tree. The yellowish-white wood is compact and fine-grained, and is well adapted for furniture and other kinds of cabinet work. It was introduced into England about the middle of the 16th century. *P. occidentalis*, the P.-T. of the E. part of N. America, is more commonly cultivated in Western Europe than the above, but is less hardy. It differs in having less deeply lobed leaves, which are pubescent when full grown. This species grows to a large size, the diameter of the trunk at times attaining 12 feet, or even more: the wood is dull red, and is not readily attacked by insects; but the tree is more suited for avenues than for a timber tree. *P. racemosa*—the Californian P.—is also a good promenade tree, and is of quick growth. The deeply five-lobed leaves are copiously clothed with woolly hairs, and have originated the name *cotton tree*. Its wood is comparatively hard and durable. The mock or Scotch P. is *Aster Pseudo-Platanus* (see MAPLE). Geological researches show that the genus *Platanus* was formerly represented as far north as Greenland. The name P. is the old French form of the Greek and Latin name. Milton (*Paradise Lost*, iv. 478) writes it 'platane'; Spenser (*Fairy Queen*, bk. i., canto i.) calls it 'the platane round.'

Planorbis, a genus of *Gasteropodous* mollusca, belonging to the section including the snails and their allies, and to the family of the pond snails (*Lymnæidæ*). The shell is flat and discoidal, its whorls lying in one plane. It is of thin texture, and has a sharp lip. *P. cornus* is a common species. The P. inhabits ponds and rivers, and has the habit of burying itself in mud during the dry season of the year.

Plant. To the question, What is a P.? the reply must be that it is difficult, perhaps impossible, to draw a hard-and-fast line between the animal and vegetable kingdoms; but this statement has usually reference to a certain confusion which arises on the border land among a mass of obscure, unicellular, or very simple organisms, which Ernst Hæckel, the great German innovator, has proposed to raise to the rank of an intermediate kingdom, under the name of Protista. Between the higher plants and animals the distinction seemed abundantly clear, and to depend not so much upon structure and form as upon fundamental differences in the mode of performance of the most essential vital functions; plants through their protoplasm acting in contact with

chlorophyll under the influence of light have the power of shaking asunder the elements of carbonic acid, water, and ammonia, and of recombining their four elements, carbon, oxygen, hydrogen, and nitrogen, into such ternary compounds as starch and cellulose, and such quaternary and higher compounds as albumen. This power, broadly speaking, the animal kingdom does not possess; and thus the vegetable kingdom must be understood to pre-exist the animal kingdom, and to be necessary for the preparation of its food. But in the young and active condition of the vegetable cell there is no chlorophyll present, and no such process takes place. The elements of carbonic acid and water are fixed and recombined in the green leaves of plants, and the more complex products are conveyed in solution in vessels, or by endosmosis to the growing points. At these points the cells are multiplying rapidly, but they are entirely pale, and have no power of performing any true P. functions. In a growing point every cell consists of an external cell-wall of cellulose, an inert ternary compound, enclosing a nucleated mass of protoplasm, or of protoplasm in conjunction with metaplasm, which gives all the manifestations of vital activity which we have in the lowest forms recognised as truly animal. Every living vegetable cell is thus (according to Professor Sir W. C. Thomson) an amœboid rhizopod, enclosed in an external shell of cellulose, a shell which it has been the active agent in secreting. Growth of the P.-shoot goes on, but this growth is produced by the multiplication by fission of the rhizopods, each division unfolding itself in a new cellulose chamber, which we recognise as an additional vegetable cell. During the past year or two some very important observations have brought this aspect of P.-life much more prominently before us. Several observers, including Dr. Nitschke, Sir Joseph Hooker, Professor Dickson, and more especially Mr. Darwin and his son Mr. Francis Darwin, have worked up very carefully the habits and the constitution of the amœboids inhabiting the cells of glandular hairs. In Mr. Darwin's curiously interesting book about *Insectivorous Plants* we have an account of the process by which *Drosera rotundifolia*—the common sun-dew—manures itself through its leaves, catches insects, and absorbs and assimilates the nitrogenous matter which they contain. Dr. Nitschke, Mr. Darwin, and others have traced the process fully, and have determined that under the stimulus of a supply of suitable food the cell-contents of the cells of the leaf-glands secrete a substance having very much the properties of pepsin, and an acid fluid closely resembling that produced in the stomach of the higher animals during the process of digestion. There is little doubt that some day many closer analogies will be shown to exist between the behaviour of plants and animals as regards nerve-physiology. Until a man begins to work at plants he is apt to grant to them the word 'alive' in rather a meagre sense; but the more he works, the more vivid does the sense of their vitality become.

Mr. J. B. Lawes has published the result of lengthy experiments, which show that 200 times the weight of organic matter elaborated by a P. passes through it in the form of water during its growth. With regard to the comparative amount of carbon assimilated by plants or evolved by animals, Professor Dewar has furnished tables which present the subject in a clear form. An acre of the best cultivated land fixes annually about 22 cwt. of carbon, and a healthy man evolves about 2 cwt. of carbon annually in the form of carbonic acid, so that eleven such persons supply as much as can be economised by an acre of land.

The number of species of flowering plants estimated as at present in existence over the surface of the globe is about 120,000, in the proportion of 9 to 2 for dicotyledons and monocotyledons. For the Cryptogamia no reliable data exists, every day adding to the number of recognised species even in well explored countries.

Planta'genet, the cognomen assumed by Geoffrey, fifth count of Anjou, and husband of the Empress Matilda, from the circumstance of his wearing in his helmet a sprig of the *planta genista*, or common broom. From him it passed to his son Henry II., and was borne by the kings of England down to the accession of the House of Tudor.

Plantagina'ceæ, a natural order of doubtful affinity, consisting of about fifty species of herbs met with through temperate regions. They usually have radiacal leaves and axillary scapes; the flowers are small and generally spiked; sepals, corolla, lobes and stamens all four; the anthers are large, versatile, and

deciduous; the ovary is free; the style filiform; the fruit a one to four-celled generally membranous capsule. The properties are unimportant. *Plantago* is the principal genus, and is represented by some common and well-known plants. *P. major*, or greater plantain, an abundant British species by roadsides, &c., has broadly ovate leaves, and a very long fruit spike, which is often given to cage-birds, that they may pick the seeds. It has followed the European in his emigration to America, Australia, &c., and is the 'white man's foot' of Longfellow's *Hiawatha*. *P. lanceolata* or ribwort has lanceolate, strongly-ribbed leaves, and a dark-coloured short spike. It grows abundantly as a weed in Britain, at the same time is often mixed with grass seed for dry Pastures (q. v.). *P. maritima*, or sea-plantain, with narrow fleshy leaves, and a spike varying from long to short, is a noticeable plant of coast marshes, and is equally at home on inland mountains, reaching an altitude of 1800 feet in the Scotch Highlands. *P. Coronopus*, named buck's-horn plantain, from its furcated leaves, and *P. media*, called lamb's-tongue, from the shape of the leaf, are locally common species. The seeds of *P. decumbens* are used to form a demulcent drink in some countries, and from those of *P. Psyllium* a useful mucilage is obtained. The leaves of *P. major* and *P. lanceolata* were formerly employed for dressing sores and wounds (see *Romeo and Juliet*, Act i., Scene 2, &c.).

Plan'tain and Bana'na (q. v.) are the two most important food products of *Musaæ*. They are obtained from closely related members of the genus *Musa*, and have been cultivated from remote times in sub-tropical Asia, Africa, and America, and the islands of the Atlantic and Pacific Oceans. The botanical name of the P. is *M. paradisiaca*, and it differs from the B. or sweet P. (*M. sapientum*) by having longer and more irregular shaped fruits, by its stem not being spotted, and by the spathe being purple instead of green inside. They probably originate in one species. In the first the fruit is often prepared by some cooking process; in the latter it is used chiefly in its raw state. The stem-like structure of these plants is not a true stem, but a vigorous shoot that springs from the rootstock, and after fruiting dies down, to be succeeded by a new sucker sent up from below, which in a few months fruits in its turn. Under favourable circumstances a hundredweight of the clustered fruit is the annual return of each plant. P-meal is simply prepared by reducing the dried unripe pulp to powder; it is palatable, digestible, and nourishing. In some countries a favourite mode of preparation is to bake the fruit in its skin, or fry slices of it with butter. In the West Indies the negroes use it boiled and beaten in a mortar. When ripe the pulp contains nearly 20 per cent. of sugar and pectose. A decoction of the fruit is a common beverage, and the expressed juice yields a kind of wine by fermentation. The young shoots are eaten as a vegetable, the large leaf-blades serve as thatch, fibres from the stems are made into cordage, and different portions of the plant have medicinal uses. *Musa* can be successfully grown for their fruit in stove-houses in Britain. Sir Joseph Paxton was the first to accomplish this nearly fifty years ago, at Chatsworth. He found *M. Cavendishii* much the best adapted for cultivation, being robust, dwarf, and yielding a profuse supply of fruit of an excellent flavour. It is a native of China, and has now been introduced with much advantage into the South Sea Islands. *M. sinianum*, found in the islands of the Eastern Archipelago, from Malacca to Sunda, produces in its cultivated varieties a very delicate fruit, which sometimes attains a length of 2 feet. *M. troglodytarum*, a native of India, &c., has small reddish or orange-coloured edible fruits. *M. ensete* or Bruce's P., was discovered by that traveller in Abyssinia. It is chiefly remarkable for its immense leaves, which sometimes attain a length of 20 feet, with a breadth of 1 yard. This species produces no suckers, and requires several years to come into flower and seed; the fruit is pulplike, but the inner part of the stem and the young spikes are used boiled as an esculent. *M. textilis* furnishes what is known as Manila hemp, for which see *ANACA*. The plantains of the English flora have no relationship whatever to the above. See *PLANTAGINACEÆ* and *ALISMACEÆ*.

Plan'tain-Eater, the name given to various species of *Insectivorous* birds belonging to the section *Conirostres*, and family *Musophagideæ*. The violet P. E. (*Musophaga violacea*) of Africa is a well-known species inhabiting Senegal and the Gold Coast. The beak is large, and expanded in the region of the forehead

to form a shield-like horny mass. The head is crimson above, and the body plumage a deep violet tinge with green lines. The tail is rounded. Belonging to the genus *Schiauritis* is the S. *gigantea* or blue P. E., whose plumage is dark blue above, and greenish below. There is a prominent black crest on the head. The food of the P.-E. consists chiefly of insects. The bird is closely related to the *Touraco*, and also in minor degree to the Hornbill.

Plantation and Planting of Trees. See *ARBORE CULTURE*.

Plantations, Law Regarding. A tenant of land under a lease is not entitled to cut down trees. In England and Ireland, however, he has an implied right of *Estovers* (q. v.). Injuring plantations is punishable by statute, and repetition of the offence may be held felony. Various acts of the British Parliaments were passed for the encouragement of planting and inclosing, and for the punishment of those destroying or injuring trees. By common law, injuries done to trees or inclosures are also punishable as malicious mischief.

Plant-Cutter (*Phytotoma*), a genus of *Insectivorous* birds, allied to the *Plantain-Eaters* (q. v.) and found in S. America. The Chilean P. (*P. rufa*) is a familiar species. It attains the size of a thrush, and derives its name from its habit of cutting the stalks of cereals with its sharp bill. The colour is grey lined with bronze above; the breast and belly are a slaty-blue. The quills of the wing and tail are black.

Plantigrada, a section of *Carnivorous* animals, including the bears, and distinguished from the *Digitigrada* (q. v.) *Carnivora*, by their placing the whole sole of the foot to the ground in walking, while the latter walk on the tips of the toes. The P. are not as a whole so markedly carnivorous as the *Digitigrada*. They subsist largely on fruits, roots, and honey.

Plan'tin, Christophe, famous among the earlier race of printers, was born near Tours, in 1514. He began the business of printing at Antwerp in 1555, and subsequently founded successful establishments in Leyden and Paris. The Antwerp house had often more than twenty presses, and was called by Guicciardini one of the wonders of Europe. P., though a man of high attainment, was inferior in scholarship to his contemporaries Aldus and Estienne. But he excelled them in enterprise and business capacity. His publications exceed in number those of either of his rivals, and are prized before theirs for accuracy and clearness of typography. The *Institution d'une Fille de Noble Maison*, traduite de Langue Toscane en François by Jean Beller (1555), is supposed to be his oldest publication; his most famous is the *Antwerp Polyglot* (see *POLYGLOT*) of Arias Montanus, towards the expenses of which Philip II. of Spain contributed six thousand ducats. Other valuable works are *Trésor du Langage bas-Allemand dict. vulgairement Flamanq*, traduit en François et en Latin (1573), and *Dialogues François et Flamans* (1579). P. died at Antwerp, July 1, 1589, and his three printing establishments were subsequently conducted by three sons-in-law. The mark of P.'s works is a hand holding a pair of outstretched compasses; their motto is *Labore et Constantia*. See *C. P.*, by F. van Hulst, in the *Révue de Liège* (1845). The quaint old mansion in the Marché du Vendredi, Antwerp, that was P.'s home and printing-office from about 1580, with its famous collection of 2000 MSS., 10,000 wood engravings, and other typographic antiquities, and library of 10,000 vols., was purchased by the city for 1,200,000 francs in 1875.

Planu'des, Maximus, a monk of Constantinople, of whom we only know that in 1327 he was sent as ambassador to Venice by the Emperor Andronicus II. He wrote homilies, orations, and a *Life of Esop*, translated into Greek the *Metamorphoses* of Ovid, Cicero's *Somnium Scipionis*, &c.; but it is as the latest editor of the Greek Anthology that he is best remembered.

Plan'ula, the name given in zoology to the general form of the embryo in *Calenterate* animals, and especially in the class *Hydrezon* (q. v.). The P. is a minute speck of protoplasmic matter, of oval shape, and having numerous cilia.

Plasen'cia, a town of Spain, province of Cáceres, romantically situated on a steep hill overlooking the Iserte, and at the entrance of a beautiful fertile valley, 43 miles N.N.E. of Cáceres. Founded in 1190, it was at one time a place of importance. It is girt by an old wall, and has a fine Gothic cathedral, begun in 1498, a ruined castle, an episcopal palace, several interesting

Gothic churches and secular buildings, and is supplied with water by means of an aqueduct of 80 arches. There are slight industries in textiles and hats. The Iserte is here crossed by three bridges. Pop. 3824.

Plasma (Gr. *plasma*, an image, or by corruption from *prasma*, 'a leak'), a variety of chalcedony, having a grass or leek green colour, streaked with whitish or yellowish specks. P. is slightly translucent, and possesses a kind of waxy lustre. It was a favourite stone with ancient engravers, many of their intaglios being cut in P. Specimens of the mineral are obtained from India and China, but it is not now much regarded.

Plassey (*Palsey*, from *palas*, the red flower of the *Butea frondosa*), a village in the District of Naddea, Bengal, British India, near the junction of the Bhagirutti and Jellinghi rivers, 96 miles N. of Calcutta. It is celebrated for the victory which Colonel (Lord) Clive, at the head of 3000 men, of whom only 800 were Europeans, gained over the army of the Nawab, Saraj-ud-Dowlah, 23d June 1757. This battle decided the fate of Bengal, and started the British on their career of conquest. The battlefield has now been entirely eaten away by changes in the river courses, and but a single tree survives of the historical mango grove beneath the shade of which Clive spent a sleepless night, and resolved, against the opinion of his council of war, to fight on the following morning.

Plastering is the covering of internal walls, ceilings, &c., in dwellings and other buildings, with plaster, for strength and elegance. The varieties of plaster used in England are mixtures of lime and sand with tanyard hair, constituting 'coarse stuff'; pure 'run' lime, with or without fine hair, called 'fine stuff'; a mixture of putty and plaster of Paris, termed 'gauge stuff,' and several kinds of 'stucco.' Well-finished work is executed with three coats; laths so covered are technically said to be 'pricked up, floated, and set,' while bricks are said to be 'rendered, floated, and set.' The setting coat on walls to be papered consists of 'fine stuff,' but for ceilings and walls to be painted, stucco, gauged thin, is used. Cornices are formed by means of moulds run along the floating coat, and again over the upper coat of gauge stuff. Enrichments or decorations are moulded in plaster of Paris. In France plaster of Paris is almost exclusively employed in P.; and of late years in England the use of selenitic mortar containing a proportion of sulphate of lime has been extending. See MORTARS.

Plaster of Paris is a soft white powder, prepared from gypsum (hydrated sulphate of lime) by reducing it to the anhydrous state by calcination at a temperature not exceeding 127° C. If this temperature be exceeded the gypsum fuses, and the powder obtained from it does not, when made into a paste with water, readily 'set' or harden, the property on which the great utility of P. of P. depends. P. of P. is extensively used in making enrichments for internal decoration, in taking casts of statues and metal-work generally, and in forming moulds for the use of the potter. It also forms the basis of many cements (see MORTARS), stuccos, and imitation coloured marbles, &c. (see SCAGLIOLA). Gypsum is abundantly distributed; but the 'plaster stone' which yields in all respects the finest P. of P. is found in the Paris basin.

Preservation of P. of P. Casts.—Recently a premium offered by the Prussian Government for the most effective method of preparing plaster casts that admit of being readily washed and cleaned was gained by Dr. Reissig of Darmstadt. He accomplished this by converting the sulphate of lime of the cast into (1) sulphate of baryta and caustic lime, or carbonate of lime, or (2) into silicate of lime by employing suitable solutions, in which the cast is suspended. A solution of hydrated oxide of barium, containing a small quantity of slaked lime, is used in the first case, and one of silicate of potash, containing free potash, in the second. By either process the cast is uninjured in sharpness, while it is rendered perfectly insoluble in hot or cold water. It however still remains porous, and collects particles of dust, which are greedily absorbed when the cast is placed in water. To obviate this evil, the transformed cast is coated with an alcoholic solution of soap, which penetrates and fills the pores; dust may then be easily removed by means of lukewarm water and a sponge. Dr. Reissig recommends the baryta water process as being the simplest and cheapest method.

Plasters. See EMPLASTRA.

Plastron, a term applied to the under part of the body or shell of tortoises or turtles, formed of a flat bony plate. The P. was formerly regarded as corresponding to the *sternum*, or breast-bone, but is now known to represent certain skin or dermal ossifications. It consists of nine pieces.

Plata, Rio de la, the name given to the estuary of the two great S. American rivers Paraná (q. v.) and Uruguay (q. v.). It is 210 miles long, 24 miles broad where it first assumes the name, and 105 miles broad at its mouth. It is shallow, the depth varying from 16 feet opposite Buenos Ayres to 60 feet at its mouth. The navigation of the estuary is rendered dangerous by strong currents and sudden tempests, while thunderstorms are also very frequent. Nevertheless, commercially, the La Plata is of great and increasing importance. Regarding its discovery, &c., see ARGENTINE REPUBLIC.

Platæa, anciently a small town of Boeotia, 6½ miles S. of Thebes, at the foot of Mount Cithæron, and commanding the pass across that range into Attica. In 519 B.C. it formed an alliance with Athens, to which it remained faithful during the whole of its subsequent history. P. sent 1000 men to Marathon, and was also represented at Artemisium. It was the scene of the victory of Pausanias over the Persians, B.C. 479, and of a famous siege in the Peloponnesian War, B.C. 420-427. It remained in ruins until 387, when the Peace of Antalcidas allowed the younger inhabitants to return from exile and rebuild their paternal homes. But they were once more expelled by the Thebans, and did not permanently return till the victory of Philip at Chæroneia in 338 put an end to all other despotism than his own. P. is mentioned as late as the 6th c., and some considerable ruins are still visible near the village of Kokla.

Platalea. See SCOPULI.

Platanista, a genus of *Cetacea* belonging to the Dolphin family, inhabiting the estuary of the Ganges. It has a very long slender muzzle, and about 120 teeth. The beak is somewhat expanded in the middle. It is of a greyish-black colour above and white below. The eyes are very small. There is no dorsal fin. The P. is familiarly known as the 'Soosoo,' and as the 'Gangetic Dolphin.'

Plat'Band (Ital. *fascia*), in architecture, a square moulding, whose projection is less than its breadth. The term is sometimes improperly used to denote the fillets between the flutes of a column. The lintel of a door or window is also occasionally called by this name.

Plate Marks, or **Hall Marks**, are certain stamped characters legibly impressed on gold and silver plate and other articles made of these metals. The most important P. M. is the assay mark, which indicates the nature and value of the metal, as tested at the various assay offices or goldsmiths' halls established throughout the United Kingdom. The hall marks for gold are a crown and figures, which indicate the proportion of gold and alloy in the article. Stamped pure gold is arbitrarily represented by 24 carats or portions, and the stamped characters '18,' '15,' '12,' '9,' and '8' in the hall mark indicate these various proportions of pure gold in the composition, the remainder of the 24 parts being composed of baser metal. By an Act passed in 1854 gold as low as 8 carat, i. e., 8 parts gold and 16 of other metal may be stamped; but a subsequent Act passed in 1855 excepted wedding rings, which cannot be stamped unless they reach the standard of 18 carat. Hall-marked silver plate must be standard—11 oz. 2 dwts. pure silver and 18 dwts. of copper. The marks consist of (1) the maker's mark or initials; (2) head of the reigning sovereign (the duty mark); (3) the lion passant (standard mark); (4) the mark of the local assay office; (5) the date letter. Twenty letters of the alphabet are used as date letters, which are changed every year, and the series of many cycles are easily recognised by the nature of the characters, which remain uniform for twenty years. Thus, with 1796 (London assay), begins A, 1816 a, 1836 H, 1856 a, and so on. An alphabetical series of P. M. can be traced as far back as 1438-39.

Plate Powder. For cleaning silver plate nothing is better than finely levigated or precipitated chalk. Jewellers rouge, which consists of a fine oxide of iron, may also be advantageously used, but it is more commonly reserved for goldsmiths' work.

Mercurial P. P., which consists of mercury intimately mixed with about 12 parts of fine lime, although much used, is very hurtful, as it rapidly erodes silver surfaces to which it is applied.

Pla'ten-Hallermund, more commonly **Platen-Hallermünde**, **August Graf von**, a German poet, born at Ansbach, 24th October 1796, studied philology at Würzburg and Erlangen, and first appeared as an author in his *Ghaselen* (Erlang. 1821). This was followed by *Lyrische Blätter* (Leips. 1821), and *Vermischte Schriften* (Erlang. 1822). The fruits of a visit to Italy are seen in his *Sonette aus Venedig* (Erlang. 1825). Later works as *Das gläserne Pantoffel*, *Das verhängnisvolle Gabel* (1826), *Der Romantische Oedipus* (1829), *Schauspiele* (Stuttg. and Tüb. 1828), *Die Liga von Cambrai* (Frankf. 1833), and *Geschichte des Königreichs Neapel von 1414-43* (Frankf. 1833). His last work was *Die Abbasiden* (Stuttg. 1835), a large poem in nine cantos. P. died of fever at Syracuse, 5th December 1835. His *Gesammelte Werke* were published at Stuttgart in 1838 (later editions 1847 and 1853). A complete edition of his *Gedichte* appeared at the same place in 1848 (new ed. 1852). P. was a true and earnest if not a great poet; somewhat didactic and formal, but pure in spirit and of high intent. See Minckwitz, *Graf P. als Mensch und Dichter* (Leips. 1838), and *Briefwechsel zwischen P. und Minckwitz* (Leips. 1836). P.'s *Tagebuch* was edited by Pfeufer (Stuttg. 1860).

Pla'ting is the art of coating or covering one metal or alloy with another. It is usually practised for the purpose of forming a superficial deposit of the precious metals gold and silver on a basis of inferior metal, but since the introduction of electroplating (see ELECTRO-METALLURGY) many other metals and alloys, possessing advantages of beauty, durability, &c., over those which they cover, are used for P. The only distinction which can now be drawn between metal gilding and silvering on the one part and P. on the other is found in the thickness of the deposit, which is, or ought to be, a feature in the latter process, although much of the plated ware now manufactured has a coating of only the flimsiest nature. In a restricted sense, the term P. specially applies to the coating of German silver or Britannia metal with silver in the manufacture of 'plate' for table use, forks, spoons, and other similar purposes, and to a like coating of 'gilding metal' with gold for making cheap lockets and other inferior jewellery. The original process of preparing plated silver, known as Sheffield plate, is still to some extent practised, and consists in soldering to one or both sides of a thick ingot of German silver, brass, copper, or other metal, a thin plate of pure silver. The soldering is done in a muffle furnace, and the surfaces must be united in the most perfect manner, while at the same time great care must be exercised to prevent the two metals from mixing and so forming an alloy. The combined ingot of inferior metal and silver is subsequently rolled out to any required tenacity, and the original relative thickness of the two metals continues the same throughout. Thus, if in the ingot the German silver was twelve times thicker than the silver, the rolled sheet will have a perfect and uniform P. of silver one-twelfth the thickness of the metal it covers. Gold P. in jewellery work is accomplished by analogous processes.

Platinum (Pt = 198) is a hard, tough, white metal, almost always found associated in its ores with the metals, palladium, iridium, rhodium, osmium, ruthenium. These metals, indeed, are never found except with P., and form a well-marked group which is distinguished as the P. group. The great infusibility of P. and its power of resisting almost all acids render it very valuable in analysis as furnishing the chemist with crucibles in which various bodies may be heated. Though hard, it is very tough, and can be drawn into excessively fine wire, or rolled into extremely thin foil. It is a comparatively rare metal. To extract the metal, the ore is treated successively with nitric and hydrochloric acids to dissolve out the commoner metals such as silver, copper, lead, &c. The residue is then subjected to the action of aqua regia, a mixture of nitric and hydrochloric acids, which is capable of dissolving the metal. The acid liquor is decanted and mixed with sal ammoniac, when a yellow precipitate of a double chloride of P. and ammonium results. This is washed and heated, and the metal, usually with an admixture of iridium, is left as a grey porous mass (*spongy P.*). This is then pressed and forged at a high temperature into bars and plates. At no temperature does the metal unite directly with oxygen;

but in the presence of caustic earths or alkalies it oxidises slowly. At a red heat it absorbs hydrogen, forming probably with that gaseous metal a true alloy. It also readily alloys with lead, tin, bismuth, and the more fusible metals, when these are fused in contact with it. P. forms two oxides (PtO and PtO_2), which, though both bases, are of little interest. There are two chlorides. Platonic chloride ($PtCl_2$) is an orange-coloured deliquescent substance, formed by evaporating to dryness the solution obtained by dissolving P. in aqua regia. Heated to $250^\circ C.$ it decomposes into chlorine and the olive-coloured insoluble platinum chloride ($PtCl_4$). At a higher temperature the whole of the chlorine is driven off. The platinum chloride forms double salts with the chlorides of potassium, sodium, and ammonium. The cyanide of P. ($Pt(CN)_2$) is a greenish-yellow powder, insoluble in water and acids, and forming with the various metallic cyanides beautifully crystallisable double salts.

Pla'to, the greatest of the Greek philosophers, was born at Aegina, B.C. 429. His father was Ariston, a member of an old and honourable family. We have few details on which we can rely regarding his life, for the anecdotes told of him by Athenæus and other gossip of antiquity do not merit a moment's attention. He was well educated, and at a very early age wrote poetry. Philosophy, however, soon absorbed him wholly, and when twenty years old he joined himself to Socrates, whose doctrines and personal character exercised a profound influence on him. After his master's death in B.C. 399, P. left Athens and travelled to Megara, Cyrene, Egypt, Magna Græcia, and Sicily. In Megara and Magna Græcia he studied the Eleatic and Pythagorean systems, and thus became thoroughly acquainted with all the results to which Hellenic Philosophy (q. v.) had then attained. When forty years of age he returned to Athens. He visited Sicily twice afterwards, but with this exception he remained at Athens for the rest of his life, teaching in the Academy, which was situated in a delightful garden near the city. Aristotle was among his pupils. He died B.C. 347, at the age of eighty-one.

P. has left a large number of writings behind him, almost all in the form of dialogues. In nearly the whole of them Socrates is the principal speaker, but the opinions put into his mouth are not, except in the earlier dialogues, at all those of the historical Socrates. The opinions intended to be conveyed are not given to any one of the characters, but rather distributed among the whole of them; even those who seemingly oppose the main current of the dialogue have their share in the development of the subject under discussion.

P.'s philosophy has, moreover, the character of an historical development, and it is only when looked at in this light that the whole appears concordant with itself. The dialogues fall readily into three groups, answering to the three periods in the life of their author. In the first group, the subjects are treated quite after the manner of the historical Socrates. We have discussions on the various virtues; thus the *Charmides* treats of Temperance or Moderation, the *Lysis* of Friendship, the *Laches* of Courage, the *Euthyphro* of Piety, and the *Protagoras* (which last may be taken as the highest example of its class) of the unity of the virtues and their identity with knowledge. In these dialogues, the faults of various definitions and the defects in the popular views of the subjects treated are pointed out; but there is no systematic body of doctrine. These writings are merely introductory; their purpose is to clear the ground.

In the second group, the positive side of the Platonic Philosophy appears. We have in the four dialogues—the *Theætetus*, the *Sophist*, the *Statesman*, and the *Parmenides*—the exposition of the ideal theory. This, which is the central point of P.'s system, may be thus stated:—Socrates, looking at the subject from an ethical standpoint, had proposed by an induction of particular instances and by definitions to attain to general notions of Justice, Temperance, Truth, &c., and P. extended his inquiry. He sought for the general notions which were contained in all existence, and these he affirmed were not mere notions of the mind, but real, indeed the only real objective existences on which all else depended. Thus there existed ideas of virtue, beauty, wisdom, and what was virtuous, beautiful, or wise in the world was only so in so far as it was a manifestation of these ideas. Everything that was known to us, however small or small, depended for its existence on ideas; and were these removed, the world would become absolute blank negation. The world, as we know

it, that is these underlying principles in conjunction with the 'things of sense,' but what these 'things of sense' are, or the exact relation between the two parts, is not clearly expressed. The non-ideal element is perhaps something requisite for the manifestation of the ideal, or it is the negation of that element, something opposed and hostile to it. These ideas do not exist apart from and independent of each other, rather they are connected in a gradation of hierarchy, at the head of which is the idea of the 'Good,' and this with P. is the same as God.

Connected with this 'ideal theory' is P.'s notion of dialectic. This is the subjective process of the mind by which we attain to true knowledge, and as true knowledge must be of the ideas (for these are the only really true existences) dialectic in an objective sense is the Science of the Ideas.

The third group of dialogues contain the application of the ideal theory to Physics, Ethics, Education, and Politics, in fact, to all the different spheres of human life. The application of the ideal theory to the creation of the world is contained in the *Timæus*, which is mythical in form. Here is described how Demiurgos (the world-forming spirit) first formed the world-soul from the eternal ideal world and the nameless chaotic mass. Into this soul, made in perfection after the image of the idea, and serving as framework, the universe was built. As the universal soul so is the individual. It partakes of the nature of the ideal world; but it is joined to a body weighed down with sensuous passions and desires. Hence the mingling of good and bad in human life. In this present life the soul has lost much of its original brightness, but it still retains a dim memory of that ideal world from which it came—hence its notions of justice, goodness, and truth. (This is the doctrine of *Reminiscence* developed in the *Phædo*.) Born of these memories, there exists in the best souls a longing after that higher state, and this is increased by the sight of beautiful and good objects. With these it desires to remain, for they vividly remind it of the ideas of beauty and goodness. (This is the famous theory of Platonic Love (q. v.) developed in the *Phædrus* and *Banquet*.) Midway between the two parts of man's nature—the sensual and the physical—is the heart (*thumos*), in itself noble, but apt to be led away and act ignobly. Hence the aim of the soul must be to rise above the sensuous to that ideal world to which it belongs. Philosophy is the path to this, and the truest philosopher is he who does it most completely; and so P.'s system becomes finally a religion and a life. The only virtue of the sensuous part is obedience—a purely negative one—but the virtue of the heart is courage; it must fight for and defend the truth, which it is the function of reason (*nous*), the highest part of the soul, whose virtue is wisdom, to discover. When all three divisions act in right measure, there arises from their union justice, the complete virtue of the whole soul. Such is the perfect man, of which the perfect state will be merely an enlarged copy. P.'s notions of both are set forth in the *Republic* and the *Laws*. The ideal state will consist of three classes, the workers, the warriors, and the rulers, to whom respectively belong the virtues of temperance, courage, and wisdom. The first class satisfy the animal wants of the community and are of little account; the second defend the State from attack; the third guide it and realise the idea of the good in their thoughts and actions. Justice is the virtue of the whole State. But how are men fitted to be responsible members of such a community? P.'s answer is his theory of Education. The youth must first be trained in music and gymnastic, i. e., his mind and body must be properly developed in accordance with the ordinary Greek view. He must then study mathematics, which stand midway between the things of sense and the ideas; and finally he proceeds to dialectic, philosophy properly so called,—the Science of the Idea. The young man must be surrounded all the time only by what is severely beautiful. All poets must be banished, for they tell lies and represent the gods as committing unworthy actions. The highest good of the State is the same as that of the individual, viz., the knowledge of the idea of the good and its realisation in life, and this (such is the final form of P.'s philosophy) requires for its accomplishment the absolute extinction of all merely human emotion and sentiment.

So much for P. as an abstract thinker. As a literary artist his merits are not less remarkable. He was not only the *Æschylus*, but the *Shakespeare* of the ancient world. His writings are perfect in point of style. They exhibit great power and distinctness in the delineation of character, infinite wealth of

thought and splendour of imagery, rising frequently into magnificent eloquence. Throughout there is exhibited the profoundest acquaintance with human life in all its phases. The dialogues are all impersonal; only twice, and then in the most casual manner, has P. mentioned himself. An under-current of humour, which sometimes almost broadens into farce, runs through each dialogue.

The whole succeeding history of human thought bears witness to the vast influence which P. exercised. His writings embrace all preceding philosophy (and that touched to far finer and profounder issues than its founders could have imagined), and all succeeding philosophy was founded on them. Aristotle, though his relation was very much that of an antagonist, borrowed many of his conceptions from him. The Neo-Platonists (q. v.) developed certain of his doctrines, and used them in the last intellectual struggle of the heathen world with Christianity. Elements of his teaching are to be found in Stoicism, in the Mystics of the Middle Ages, and in the Hegelian Philosophy. The mere mention of the Cambridge Platonists, of whom Cudworth (q. v.) may be taken as a type, shows that his influence was felt in our country; and in the *Republic* is to be found the original of Cicero's *De Republica*, of St. Augustine's *City of God*, and of Sir T. More's *Utopia*. His influence can never cease to be felt. He belongs to the future as much as to the past, for, like the philosopher of his own conception, 'he was the spectator of all time and of all existence.'

See the complete editions of P. by Baiter, Arelli, and Winckelmann (1842; smaller ed. 1852), Stallbaum, (1867; with Lat. notes, 21 parts, 1836-39), and C. F. Hermann (6 vols. 1871); the Ger. trans. by Müller and Steinhart (8 vols. 1853-66); Fr. trans. V. Cousin (13 vols. Par. 1825-40); and Eng. trans. Jowett (2d ed. 5 vols. 1876); Grote, *P. and the other Companions of Socrates* (3 vols. 1865); Steinhart, *P.'s Leben* (1873); Zeller, *P. and the Older Academy* (Eng. trans. 1876). For a popular account, consult Whewell's *Platonic Dialogues for English Readers* (3 vols. Camb. 1859-60-66), and the volume by Collins in Blackwood's *Ancient Classics for English Readers* (1870-78).

Plat'off, Matvei Ivanovitch, Count, was born on the banks of the Don, August 6, 1757. He began his military career in the Turkish campaign of 1770, served under Suvorof in 1782 and 1783 in Kuban and the Crimea, and distinguished himself at the taking of Otchakof in 1788, at Bender in 1789, and at Ismael in 1790. In 1801 he was appointed Hetman of the Cossacks by the Czar Alexander I. P. served against the French 1805-7, and in the Turkish campaign of 1809. But he distinguished himself chiefly in the war of 1812 in the retreat of the French from Moscow. With his twenty regiments of Cossack cavalry he followed their retreat closely and without intermission, and caused, in the opinion of the French, no less loss than did the famine and the cold. He inflicted great loss at Wjasma, Dorogobusch, near the village of Erzowo, at Swenichi, Borisso, Poguljanka, and Kowno, but was driven back at Malo-Jaroslawetz and Krasnoe, losing his only son, to whom he had hoped to bequeath his power, at Vereia. In 1813 he went through the campaign in Germany, and defeated Lefebvre at Altenburg. In 1814 with the allies he entered France, where the fire and pillage of his irregular hordes were long remembered by the inhabitants of the country between the rivers Seine and Marne. In Paris P. found a reception which said little for the patriotism of the French, and on his visiting London with Blücher he was welcomed and presented with a sword of honour. On his return to Russia he was loaded with honours—he had been created a count in 1812. P. died at Tcherkask, 15th January 1818, and was buried in Novo Tcherkask, where the Emperor Nicholas erected a monument to him in 1853. His life has been written by Smirnoi (3 vols. Mosc. 1821).

Platonic Love. The philosophy of Plato was not an attempt to explain to the intellect the mysteries of the universe, but to reach the true method of the higher life. Owing to this practical aim love occupies a prominent place in the writings of the Greek philosopher. But it is especially in the *Phædrus* and the *Symposium* that his theory of love is fully developed. In the latter dialogue the various interlocutors pronounce discourses of love. In one of these, that delivered by the comic poet Aristophanes, the theory is propounded that the male and female formed originally one being; that in process of time this human being was cut into two, and love in man now is the search

after the lost half. That man is happiest who is successful in obtaining the exact counterpart of his own mind, and he comes next who obtains a love as congenial as possible. It is, however, in the discourse of Socrates in this dialogue that Plato's own idea of love appears. Socrates affirms that he received his instructions in love from a foreign woman, Diotima. Love itself is the child of Plenty and Poverty. It is ever striving after something, and is always in want. But what it seeks is the beautiful and the good, and it proceeds from one degree of blessedness to another. This love appears in all mankind, and pervades all the phases of human activity, though it is generally called love only when it takes the special form of affection for individuals. But even in this form it is a striving after the beautiful and the good. Love longs to propagate; it hankers after immortality. And so the person seeks the beautiful, in which, as it were, to continue his existence. But love is not content with the merely beautiful in outward appearance. It seeks the truly beautiful which is identical with goodness, and the two lovers unite to propagate in each other beautiful ideas and beautiful action. Then the true lover passes from the individual. He at first sees beauty in a single person, and loves it there. He sees beautiful ideas in a single person, and loves them there. But he moves onwards to the contemplation and love of the ideas themselves, until at length he reaches the perfectly beatific state in which the immortal surpassingly lovely idea of Beauty is revealed to him in its absolute existence, and forms for ever the joy of an eternal life.

Platoon (Fr. *peloton*, 'a ball of thread'), formerly a small square of musketeers, sixteen going to each battalion. The word is now applied to a number of recruits assembled for instruction. 'P. exercise' consists of the operations required for the loading and firing of the rifle, as distinct from manual exercise, the carrying of the rifle in different positions.

Plattdeutsch, or **Low German**, the provincial dialect of the N. German plain extending from Holland to the Russo-Polish frontier, and from Tondern in the N. as far S. as Aachen, Kassel, Wittenberg, and Thorn (see GERMAN LANGUAGE). A descendant of the Old Saxon of the *Heland*, P. is still to some extent a literary dialect, possessing several versions of the Scriptures, and boasting at least two well-known names—Fritz Reuter and Klaus Groth. The former of these writers was born at Stavenhagen in Mecklenburg-Schwerin, November 7, 1810, was for five years imprisoned in a fortress as a demagogue (1833-38), and died at Eisenach, July 12, 1874. In his *Lauschen und Rimels* (Treptow, 1853) and prose *Ollen Kamellen* (7 vols. Wismar, 1860-68) he has sketched the German peasant life with a truth and vigour that have gained these works a boundless popularity among the peasants themselves; and 'rhapsodists,' says a German writer, 'wandered in the poet's lifetime from village to village reciting and interpreting his merry, touching tales.' Reuter's *Sämmtliche Werke* have been published at Wismar (14 vols. 1865-75), and his *U' de Franzosentid* has been translated into English under the title *In the Year '13*. Klaus Groth, born at Heide in Dithmarschen, April 24, 1829, and since 1859 a professor at Kiel, has written *Quickborn* (1853), *Vertel'n* (4 vols. 1855-59), *Rothge der Meister Lamp* (1862), and other poems, all in the same vein as Reuter's *Lauschen*, and hardly less popular than they. In 1877 Dr. Door translated into P. the *Merry Wives of Windsor* (Ebbw), with an introduction by Groth. Neger's *Grammatik des Mecklenburgischen Dialects* (Leips. 1869) and Lübben and Schiller's *Mittelmeiderdeutsches Wörterbuch* (Bremen, 1873) are the best authorities on P., and the 'Verein für niederdeutsche Sprachforschung,' founded in 1875, publishes a yearly account of its transactions. See Max Müller's 'Language and Poetry of Schleswig-Holstein' in vol. iii. of *Chips from a German Workshop* (Lond. 1870).

Platte, one of the largest tributaries of the Missouri, is formed in Nebraska, U.S., by the union of two streams called the N. and S. Forks, both rising in Colorado. The united stream, after an easterly course of 900 miles, enters the Missouri at Plattsmouth. In the upper part of its course it is of great use as a source of water-power, but towards its mouth it becomes very broad, and so shallow as to render navigation impossible. Its chief tributary is the Elkhorn. Drainage area, 7500 sq. miles.

Platt'en-See. See BALATON.

Plattsburg, a town of New York, U.S., is situated on both banks of the Saranac river, where it enters Lake Champlain, and is connected by rail with Montreal and Whitehall. It has a commodious harbour, extensive barracks, three hotels, six churches, and three newspapers. Here the British squadron on Lake Champlain was defeated by Commodore M'Donough, 11th September 1814. Pop. (1870) 5139.

Platycrinus, a genus of fossil Crinoids or lily-stars. *P. tricotadactylus* of the Carboniferous series is a familiar species. The stalk or column was of oval or elliptical shape, and had its articulating surfaces or facets marked by striae or lines radiating from the centre of the joint. P. is one of the Paleocrinoids or older group, attaining its highest developments in Paleozoic rocks.

Platyel'mia, a group of *Scolecida* (q.v.), comprising those forms which have bodies of flattened shape. The tapeworms (*Tamada*), flukes (*Trematoda*), and *Turbellaria* are included in this division.

Platypus. See ORNITHORHYNCHUS.

Platyrrhina (Gr. 'broad-nosed'), a genus of *Quadrumania* or Monkeys, confined to the New World. In this division the Marmosets (*Haple*), Spider monkeys (*Ateles*), Howlers (*Myodes*), the Capuchins (*Cebus*), &c., are included. The P. have no callosities or cheek pouches. The tail is long and is usually prehensile. The thumbs are wanting in *Cebus*. The nostrils are placed far apart and separated by a broad septum—hence the name 'P.' The premolar teeth number 6 in each jaw. These monkeys live on trees.

Platystoma (Gr. 'broad-mouthed'), a genus of Teleostean fishes included in the family of the *Silurida* or Sheat fishes. The name is derived from the broad form of the mouth, which has barbules or tactile filaments. There are two dorsal fins, and the skin is naked. The P. is represented by various species occurring in the rivers of S. America, and especially in those of the S.E. part of the Continent. *P. tigrinum* is a familiar species, noted for the delicacy of its flesh. The name P. is also given to a genus of *Gasteropodous* mollusca, the shells of which occur in rocks of Triassic age.

Plau'en, a town of Germany, in the Saxon Voigtland, lies in a beautiful valley on the White Elster, 28½ miles N.E. of Hof by rail. It is overlooked by the ancient Hradschin. The most prominent building is the Johanniskirche, with two spires. P. has a school of architecture, a seminary for teachers, and a *Realschule* of the first rank, with which is connected a gymnasium. It is the chief centre of the Saxon manufacture of white cottons (muslins, mulls, jaconets) and cambric. Tanning, dyeing, wigogne and cotton-spinning, and the manufacture of cere-cloth, nets, embroidery, paper, and machinery are also important industries. Pop. (1875) 28,756.

Plautus, T. Maccius, often erroneously called **Marcus Accius Plautus**, the most famous comic poet of Rome, was born at Sarsina in Umbria. The period of P. has been a matter of much controversy. The conclusions of Ritschl, as given in his admirable essay *De Etate Plauti*, viz., that P. was born about 254 B.C., commenced his career of comic poet about 224 B.C., and died 184 B.C., seem most worthy of acceptance. The little that is known regarding his life is derived from a passage in Varro quoted by A. Gellius (iii. 3), the substance of which may be briefly given: P. came to Rome at an early age; was first employed as a workman for the actors; saved a little money; embarked in business; lost his means; and to gain a living was obliged to work at a hand-mill grinding corn for a baker. To P.'s early residence in Rome must be ascribed his intimate acquaintance with the Latin tongue, his complete mastery of its idiom, and his familiarity with the dramatic literature of Greece. At all events, it seems certain that while engaged in the humble calling of corn-grinder he produced three plays—the *Saturia*, *Addicus*, and a third, the name of which is not known. P.'s career, commencing at 224 B.C., was continued till 184 B.C., during which time he produced comedy after comedy with unflagging energy and wonderful fertility. Of 130 plays ascribed to him only 20 remain. Of the 130, however, many were considered spurious by Roman critics, and it seems not improbable

that some of them were written by one Plautus, the likeness of whose name to the great comic poet's caused them to be attributed to the latter. *Vestris* himself limits the genuine plays of P. to 21. Of these he presents 20, the titles of which are:—(1) *Amphitruo*; (2) *Aulularia*; (3) *Aulularia*; (4) *Captivi*; (5) *Cureuli*; (6) *Casina*; (7) *Castellaria*; (8) *Epidicus*; (9) *Bacchides*; (10) *Mastellaria*; (11) *Misamichus*; (12) *Miles gloriosus*; (13) *Mercator*; (14) *Penulus*; (15) *Panulus*; (16) *Persa*; (17) *Rudens*; (18) *Stichus*; (19) *Pseudomachus*; (20) *Truculentus*. The 21st, *Vidularia*, was extant in the time of Priscian; moreover the Milan Palimpsest contains several lines from the same play. As a writer P. occupies an important place in the literature of Rome. His name, however, is not of the highest, although his popularity with his countrymen was immense. Lettered and unlettered alike rejoiced to do him honour, and for 500 years his plays held possession of the Roman stage. As a poet P. was intensely national. His plays are to a great extent reproductions of the witty, vigorous, and brilliant Attic comedy. But he has transfused into them a style, spirit, and character essentially Roman, and therein lies his charm. In modern times P. has found no lack of imitators and translators. The *editio princeps* of the complete works of P. was published at Venice in 1472. The best modern editions of the complete works are those by Fr. H. Bothe (Berl. 1809-11); C. W. Weise (1837-47; new ed. Tauchnitz, 1866); and that by A. Fleckeisen in the *Bibliotheca Teubneriana* (Leips. 1859). The commentaries on the special plays by Ritschl are, however, by far the most important contributions both as regards acuteness and learning yet made to the literature, history, and criticism of P.

Playfair, John, a Scottish natural philosopher, was born at Benzie in Forfarshire, March 10, 1748. When fourteen he entered the University of St. Andrews, where he displayed such talent in mathematics and the allied sciences, that within a few years after his matriculation he was intrusted with the duties of the chair of Natural Philosophy during the illness of the professor. In 1766 he was candidate for the Mathematical chair at Marischal College, Aberdeen. His non-success was probably due to his extreme youth. Having failed in his candidature in 1772 for the then vacant chair of Natural Philosophy in his own university, he was compelled in order to support his mother and her family to enter the Church. In 1782 he resigned his living and became tutor to the sons of Mr. Ferguson of Raith. Three years later he was appointed joint-professor with Dr. Andrew Ferguson of Mathematics in Edinburgh University, and on the death of Dr. Robison in 1805 succeeded to the chair of Natural Philosophy. He died at Edinburgh, July 19, 1819. His works are *Elements of Geometry* (1795), still the text-book in the Edinburgh University; *Illustrations of the Huttonian Theory of the Earth* (1820), in which he strongly supported this theory (see HUTTON); and *Outlines of Natural Philosophy* (1812 and 1816), of which a third volume was promised but never published. From 1804 he frequently contributed to the *Edinburgh Review*, criticising the trigonometrical surveys of England and France, and the works of Laplace, Zach, and Kater. In the *Transactions* of the Royal Society of Edinburgh appear numerous and varied papers by P. on more technical subjects, while to the *Encyclopædia Britannica* he contributed 'Æpius,' 'Physical Astronomy,' and an incomplete 'Dissertation' on the progress of mathematical and physical science since the revival of letters in Europe. A collected edition of P.'s works in 4 vols., with a biographical sketch, was published in 1822. See an elaborate notice by Jeffrey in the *Annual Biography* for 1820.

Playfair, Lyon, son of Mr. George P., chief inspector-general of the hospitals of Bengal, was born at Meerut, May 21, 1819, and commenced his chemical studies at St. Andrews and the Andersonian University, Glasgow (1834). After revisiting India to recruit his health (1837), and studying organic chemistry under Liebig at Giessen (1838), he became head of some large calico printworks at Clitheroe, whence he was called to the chair of Chemistry in the Manchester Royal Institution (1843). He served on the commission to inquire into the sanitary condition of towns (1844); for his services as special commissioner of juries in the Great Exhibition of 1851 was made a Companion of the Bath; and received a joint-secretaryship with Mr. Cole in the newly-founded department of Science and Art (1853). He became inspector-general of Government museums and schools

of science (1856), President of the Chemical Society of London (1857), and Professor of Chemistry in the University of Edinburgh (1858), besides acting on the mines, Scotch fisheries, cattle plague, and other commissions. A Liberal in politics, he has represented since 1868 the Universities of Edinburgh and St. Andrews, held office as Postmaster-General in the Ministry of 1869-74, being also made a Privy Councillor, and was President of the Civil Service Inquiry Commission (1874). P. is an LL.D. of Edinburgh (1869), a member of many learned societies, and an officer of the Legion of Honour and four other foreign orders. Besides some translations of Liebig's works, he has published *Science in its Relation to Labour* (1853); *On Primary and Technical Education* (1870), and other treatises.

Playford, John, a writer and publisher of music, was born in 1613. His *Introduction to the Skill of Music* passed through ten editions from 1665 to 1684. He also published *Court Ayres* and *Psalms and Hymns in Solemn Music*. He died about 1693. His son, Henry P., published *Orpheus Britannicus*, the celebrated collection of Purcell's works.

Pleadings, in law. These are the statements in legal form of the facts which constitute the plaintiff's cause of action, or the defendant's ground of defence. The action, or suit, begins by the plaintiff delivering to the opposite party a *declaration*, or written statement, of the title of the court in which it is brought, the county, or *Venue* (q. v.) in which it is to be tried, and of the ground of action. Notice is then given to the defendant to put in his answer. In Scotch law, see CONDESCENDENCE.

Pleas, Legal, in the law of England, are of various kinds, consisting of any allegation by which the defendant endeavours to frustrate the suit—as by objecting to the jurisdiction of the court, denying the validity of the plaintiff's claim, or by pleading a tender of payment. A defendant may also plead the operation of the Statute of Limitations.—**P. in Law**, in Scotland, are defined as 'a short and concise note, drawn and signed by counsel, of the P.-in-law on which the action, or defence, is to be maintained.'

Plebeians (Lat. *plebei*, from *plebes* or *plebs*, 'the crowd,' containing the same root as *pleo*, *plenus*, and Gr. *plēthos*, and perhaps *polis*), in ancient Rome, were the body of commons, one of the two great elements of the Roman nation. From the earliest period there existed, side by side with the Roman burgesses, their *clientes* or 'listeners,' so called from their dependence on the several burgess-households. According to the hypothesis of Niebuhr, before whose time the most inconsistent views were held respecting the origin of the P., the original *populus* of Rome consisted solely of the Patricians (q. v.) and their Clients, these Clients being entirely distinct from the Plebs, which was composed of the inhabitants of various Latin towns who were conquered by the Romans and transferred to Rome or its neighbourhood. Mommsen and Ihne, however, identify the Clients with the multitude (*plebes*), maintaining 'they were so termed negatively with reference to their want of civil rights.' In the prosperity of the regal period, the numbers of the P. increased with great rapidity, and as they included a large number of families which had been noble and powerful in the conquered cities, they felt all the more severely their political degradation, and gradually entered on their celebrated struggle with the Patricians, which, for the noble spirit of forbearance and deference to constituted authority displayed by the P., is altogether without parallel save in the history of England. See ROME, HISTORY OF.

Plebiscite (Lat. *plebiscitum*, 'decree of the people,' i.e., of the *Comitia Tributa*), in France, is now applied to certain resolutions submitted to the universal suffrage of the nation, as by Napoleon I. in 1799 and 1804, and by Napoleon III. in 1852 and 1870. In May of the last-named year, 7,258,379 votes were recorded in favour of the revised imperial constitution against 1,530,000; in the succeeding November the institution of a Republic was confirmed by 557,996 Ayes against 62,638 Noes.

Plecotus, a genus of *Cheiroptera* (q. v.) or Bats, including the *P. communis*, the common long-eared bat of Britain, and other species. In this genus, which belongs to the insectivorous family *Vespertilionidae*, the ears are large, and are united at their basis. The teeth number 36. The length of the *P. communis* is 3 inches, its wing membrane when spread out to its fullest extent from 13 to 14 inches. The fur is a greyish-brown.

Plectognathⁱ, a well-known subdivision of Teleostean fishes, represented by the trunk fishes, tile fishes, globe fishes, &c. In this group the maxillary and premaxillary bones are firmly ossified and connected on each side of the head or jaw. The skeleton itself may be incompletely ossified, the spine being present in a cartilaginous condition. The exoskeleton exists in the form of ganoid scales or bony plates, and the ventral fins are wanting. The air-bladder is a closed sac.

Pledge is a movable subject put into the hands of a creditor by his debtor in security of a debt, or of an advance of money, which subject the creditor is bound to redeliver on receiving repayment. Should the subject perish without any fault imputable to the creditor, the loss falls on the debtor, as being the proprietor, and the creditor is entitled to the expense profitably disbursed on the subject while in his hands. In England, the pledgee may sell the P. if the debt is not paid at the date agreed on, or within reasonable time after giving notice. In Scotland, the P. cannot be sold without judicial authority.

Pleiades (Gr.), in Greek mythology, were the seven daughters of Atlas and Pleione. They were the sisters of the Hyades, whose death, or that of their father Atlas, so grieved them that they made away with their own lives, after which they were set as a cluster of stars on the neck of the Bull, which, from its resemblance to a bunch of grapes, was sometimes called *Botrys*. In another myth the P. are virgin companions of Artemis. Pursued, with their mother Pleione, by the hunter Orion, they pray to the gods for rescue, and are metamorphosed into doves (*Peleiades*), and placed among the stars. Their names were *Elektra*, *Maia*, *Taygete*, *Alkyone*, *Kelaine*, *Strophé*, and *Meropé*. By the Romans the P. were called *Urgula*. In the group of stars called the P., or 'Seven Stars,' the naked eye can discern only six. The telescope discovers many more. Kepler found 32, De Rheita 118. The brightest, Alkyone (η Tauri), is of the first magnitude. According to Madler's hypothesis, the central sun of the universe is in this constellation.

The Pleiad, in literature, a collective term applied by Ptolemy Philadelphus to the seven contemporary poets—Callimachus, Apollonius of Rhodes, Aratus, Homer the younger, Lycophion, Nicander, and Theocritus. In imitation of this a 'Literary Pleiad' was formed under Karl the Great, in which Alcuin was called Flaccus Albinus; Adalard, Augustin; Angilbert, Homer; Riculf, Damocetas; and Karl himself, David. Warnefrid, and one other made up the seven. In French literature, however, the name P. is especially applied to a society of seven French *littérateurs*, who in the 16th c. set themselves to work for the reform of the French literature and language after classic models. Its members were Ronsard, Du Bellay, De Baif, Dorat, Beillean, Jodelle, and Pontus de Thyard.

Plesiosaurus, a genus of fossil Reptilia, the remains of which occur in the Upper Oolite formations. The neck was short, and the head relatively large. The jaws were well provided with teeth. The P. was nearly allied to the *Plesiosaurus* (q. v.).

Pleistocene (Gr. 'most recent'), or **Post-Tertiary Period**, includes all the more recent formations which contain fossils still represented among living species. The fragmentary character of many of these formations renders it difficult to fix them in chronological order. In the Norwich Crag of the Pliocene, which was no doubt the precursor of the P., there is incontrovertible evidence that the climate of the W. of Europe was becoming colder. There was thus a gradual preparation for the Glacial Age, which is regarded as the earliest P. period. The characteristic formations of the Glacial Age are—1. Occasional deposits of gravel and sand, with plant and mammalian remains underlying the Boulder Clay; 2. the Boulder Clay or Till, a mass of unstratified clay, with striated and ice-marked blocks and boulders stuck promiscuously through it; 3. the Marine Drifts, Kames, and Eskers, resembling the Till, but bearing evidence in its stratification and fossil contents of having been deposited under the sea, and thus indicating a submergence of the land during the rigours of the great ice age; 4. the Erratic Boulders, carried probably by floating ice, and resting on the kames and gravel ridges; 5. the Moraines of the valley glaciers, which gradually shrunk up from the lower valleys to their mountain fastnesses as the climate ameliorated; and 6. the Raised Beaches which occur at various heights all round our country, and

mark the geological epochs at which the land halted for a space during its emergence from the ocean. This classification is drawn up from a consideration of Britain alone; but everywhere in the now temperate regions of the northern hemisphere there is abundance of evidence that a widespread glacial climate existed. The glaciers of the Alps, Himalayas, Rocky Mountains, &c., are the remains of a much more extensive glacier system, which once filled the mountain valleys. Various explanations of this rigorous climate of bygone days have been advanced, such as alteration in the distribution of land and water, alteration in the earth's axis of rotation, passage of the solar system through a colder region of space, variation in the quantity of light and heat received from the sun, and so on. The only hypothesis, however, which has withstood a first criticism, is that advanced by Dr. James Croll. The prime cause he finds in the varying eccentricity of the earth's orbit; and this, combined with the precession of the equinoxes, may give such a succession of the seasons as to suggest a possibility of a long winter alternating with a short summer. The whole hypothesis is ingeniously elaborated in all its bearings; but the time demanded since the beginning of the Glacial Age, 240,000 years, namely, seems, upon physical grounds, to be much too long. (See EARTH.) The later formations of the P. P., known as the recent or prehistoric, introduce the human period. Four periods are recognised: (1.) the Palæolithic Age, or period of rough stone weapons; (2.) Neolithic Age, or period of polished stone weapons; (3.) Bronze Age; and (4.) Iron Age. Remains of Palæolithic man are found in cavern deposits and ancient river gravels; and by some geologists are supposed to indicate a preglacial existence. To the Neolithic Age belong the lake-dwellings of Switzerland, and the peat mosses and Kjökenmødding of Denmark. The succeeding bronze and iron ages transformed man gradually from a rude savage, living by the chase, into a barbarian herdsman or husbandman, until they merge into true historic times. See James Geikie's *Great Ice Age*, Lyell's *Antiquity of Man*, and Lubbock's *Prehistoric Times*.

Plenishing, in the law of Scotland, means the furniture of a house or the stocking of a farm.

Plenty, Bay of, a bight on the N.E. coast of the N. Island of New Zealand, so named by Cook on account of the abundance of food and water he there obtained. It is about 100 miles wide, and is studded with a number of small islands, one of which contains a hot lake, geysers, and mud springs. The shores of the B. of P. are for the most part thickly wooded, but the western portion is more open, and adapted to agriculture and sheep-farming. The principal settlement is Tauranga, near the W. extremity. It has a good harbour.

Pleonasm (Gr. *pleon* or *pleon*, 'more'), or **Redundancy** (an overflow; lit. 'wave on wave'; Lat. *re*, 'again,' and *unda*, 'a wave'), is a term in Rhetoric, denoting such additions of language as are not required to bring out the sense, and might therefore be spared; e.g., in the sentence, 'It is the universal opinion of all men,' the words italicised mean the same thing, and either is therefore sufficient.

Plesiosaurus, a well-known genus of fossil Reptilia, forming the type of the order *Sauropterygia* of Owen, otherwise known as the *Plesiosauria*. The characters of the order may be taken as those of the genus, and consist in the absence of any exoskeleton in the form of hard plates or scales, such as living reptiles usually have. The bodies of the vertebræ were simply flattened at either extremity, and their transverse processes were large. The anterior ribs had simple heads, and the sternum or breast-bone appears to have been absent, no sternal ribs existing. There were structures known as 'false' or 'abdominal' ribs, probably imbedded among the muscles of the abdomen, and the sacrum consisted of two vertebræ. The neck was very long, forming one of the most characteristic points in the anatomy of the P., and presenting a marked contrast to the short-necked *Ichthyosauri* (q. v.). The limbs were well developed, and formed swimming-paddles. No supernumerary 'marginal' vestiges existed in P. as in *Ichthyosaurus*, and the shoulder-girdle included two clavicles, with an interclavicular element or episternum. The teeth were developed from distinct sockets. The eyes were large, a fact revealed by the size of the orbits, but the outer layer of the eye was not strengthened as in *Ichthyosaurus* by a circle of horny (sclerotic) plates. The fossil remains of P. occur

chiefly in the Liassic and Oolitic formations, their geological range extending to the Chalk. They died out in the latter formation. The length of these reptiles varied from 16 or 18 to 20 feet. Over twenty species are known, a familiar species being the *P. deltoideus*, from Liassic strata. Of the *P.*, Conybeare remarks, 'that it was aquatic is evident from the form of its paddles; that it was swiftness is almost equally so from the remains with which it is universally associated; that it may have occasionally visited the shore, the resemblance of its extremities to those of the turtles may lead us to conjecture; its movements, however, must have been very awkward on land, and its long neck must have impeded its progress through the water, presenting a striking contrast to the organisation which so admirably fits the *Ichthyosaurus* to cut through the waves. . . . It swam upon or near the surface, arching back its long neck like a swan, and occasionally darting it down at the fish which happened to float within its reach.'

Plethora (Gr. 'fulness or excess'), designates a morbid increase of the blood, beyond the wants of the system, of those constituents of the blood upon which its nutritive and stimulant properties depend, and to which it owes its peculiar character, such as the red corpuscles, fibrin, and albumen. There is no distinct proportion of the active principles of the blood which is alone compatible with health, and it is only when derangement is threatening, or obviously present, that the condition is called *P.* There may be no absolute increase of the blood; but if the wants of the system for the support of its various functions should diminish, there may be *P.*; for the loss of balance between the supply and consumption constitutes the affection. The symptoms of *P.* are florid cheeks, redness of the lips, tongue, conjunctiva, and mucous surfaces generally. The pulse is full, strong, and somewhat accelerated, and there is a feeling of heaviness and a disposition to sleep, with a sense of fullness or tension in the head, vertigo, tinnitus aurium or headache, and sometimes palpitation and oppressed breathing. Excessive eating, especially of animal food, stimulating condiments or drinks, and indolent or sedentary habits, are the most efficient agents in the production of *P.* *P.* is said to be *sthenic* when the strength and irritability of the muscular fibres are fully or excessively developed; and *asthenic* when there is a deficiency of contractility and tone in the muscular fibres; but the principle of division is not in all cases well marked.

In the treatment of *P.*, reference must be had to its cause and duration. In mild cases the diet should be restricted to vegetable food or milk, and saline laxatives should be administered. In severe cases, should apoplexy or pulmonary congestion be threatening, venesection should be had recourse to; but a permanent cure can be effected only by removing the cause, and the abstemiousness should be in proportion to the obstinacy of the case.

Pleura, the lining membrane of the thorax or chest. The *P.* is one of the *serous* membranes, and consists of a double layer. One layer or surface of the *P.* covers the lungs; another lines the internal surface of the thorax. The former is named the *visceral layer* or *P. pulmonalis*, the latter the *P. costalis* or *parietal layer*. A space is thus seen to exist between these two which receives the name of the *cavity of the P.* It follows from the disposition of the *P.*, that each *P.*, or part covering a lung, is a shut and closed sac. The two pleural sacs do not communicate in any way with one another, and they touch only at one point in front. The *mediastinum* is the name given to the space existing between the pleura; this space containing all the viscera of the chest (heart, &c.) save the lungs. The disposition of either *P.* may be traced from the breast-bone or sternum, from which it passes outwards, covering the costal cartilages, ribs, and intercostal muscles; behind, it passes over the *sympathetic nervous ganglia*, and the sides of the bodies of the vertebrae, where it is separated from its neighbour sac by a small space—the *posterior mediastinum*. From the spine the *P.* is reflected on to the side of the *pericardium* or heart-sac; thence it passes to the back part of the lung at its root, while a triangular fold passes to the *diaphragm*. This fold is the *broad ligament of the lung*. The *P.* then goes over the convex part of the lung and invests the organ generally, while below it covers the thoracic surface of the diaphragm. The right pleural sac is shorter and wider and reaches higher in the neck than its neighbour. The inner surface secretes a serous fluid, facilitating the movements of the lung in breathing.

The nerves are derived from the *phrenic* and *sympathetic*, and its blood-vessels from the internal mammary and other arteries.

Pleuracanthus, a genus of fossil *Elasmobranchiate* fishes, belonging to the Rays. The remains of *P.* consist chiefly of fin-spines or *ichthyodontoites* which occur in the Carboniferous rocks. The spines were provided with a double row of sharp processes or 'teeth.' *P.* remains are the oldest known fossil traces of Rays.

Pleurisy, or inflammation of the serous membrane lining the walls of the thorax and investing the lungs, is one of the most serious diseases of the chest. *P.* may be single or double, according as one or both sides are affected; and it may be either acute or chronic, simple or complicated. *P.* without pneumonia is much more common than pneumonia without *P.*; but when both are present, the correct term for the affection is *pleuro-pneumonia*. In acute *P.* the attack is usually sudden, and there may be no premonitory chill, as is usual in cases of pneumonia. An acute lancinating pain is usually felt in the mammary region, which is increased by coughing, and by taking a deep inspiration, and the pain is often so severe that inspiration is voluntarily impeded, and there is an impossibility of assuming certain positions. The pain is generally restricted to one small spot, although the inflammation may pervade a considerable extent of surface. The cough is short and dry, or is accompanied by slight expectoration. These symptoms are attended with headache, anxious countenance, rapid pulse, and hot skin; but the temperature, although fluctuating, does not rise so high, nor decline so rapidly, as in pneumonia. The physical signs of *P.*, as elicited by auscultation and percussion, are by far the more important; for pain in the region mentioned may be muscular only. In the early stage of *P.* the opposed pleural surfaces may be heard grating against each other, and producing what is termed the 'friction sound;' but this sound lasts only for a short time, and may disappear from resolution. Adhesions may form between the opposed serous membranes, or, as more frequently happens, an effusion of serum may take place in the cavity. Sometimes the serum degenerates into pus, constituting 'empyema.' When effusion has taken place dulness is elicited on percussion, and the dulness may be complete or partial according as the fluid fills the whole or only a portion of the cavity. When the effusion is partial, the region of dulness varies according to the position of the patient as the fluid gravitates towards the most dependent part. In the condition called *empyema*, the pus may force its way into the lung through the pulmonary pleura, and the matter is evacuated by expectoration; or it may discharge externally through an intercostal space. When the internal opening remains it is termed a bronchial fistula; and when the external opening remains it is called a parietal fistula. Air and pus may thus reach the cavity, giving rise to *pneumothorax* and *hydro-pneumothorax*. When the cavity is filled with serum the lung is pressed back against the vertebral column, and the pressure may be so great as to prevent the entrance of air into the lung, so that no breath-sounds can be detected. Increased resonance and bronchial breathing may, however, be detected at the back, the part where the lung is adhering. The vocal resonance appears faint, distant, and trembling, like the bleating of a goat, and hence the term *cephophony*. The breathing function of the lung being suspended, additional work is thrown upon the sound lung, and the respiration sounds are intensified, giving rise to puerile breathing. The patient inclines to lie on the affected side or on his back if the *P.* is single, and if there is much effusion. The duration of an attack of *P.* may vary from five or six days to as many weeks.

Treatment.—When seen in the first stage, leeches should be applied to the seat of the pain, followed by hot poultices; and a purgative should be administered. The application of straps of sticking plaster to the affected side has been found useful in preventing effusion, and counter-irritation by means of blisters is beneficial. When effusion has taken place, a combination of squill, digitalis, and mercury may be given; and this should be followed by the iodide of potassium, and the local application of small blisters or the iodide of mercury ointment. In some cases it is necessary to perform paracentesis by the pneumatic aspirator, the most convenient site for the operation being at the inferior angle of the scapula of the side affected.

Pleurisy-Root. See BUTTERFLY-WEED.

Pleurobrach'ia, a typical genus of *Ctenophore* animals belonging to the order *Ctenophora* (q. v.). *P. pilcus* is a well-known species, attaining the size of a lemon or orange, and having a body of the shape of these fruits, and of clear colourless nature and gelatinous consistence. The mouth is at one extremity or pole of the body, which is divided into spaces externally by eight meridional bands of *cilia*, arranged in comb-like fashion and named *ctenophores*. Two long tentacles are also present, which are capable of being retracted at will. From the stomach of *P.* three pairs of canals (*radial*, *apical*, and *paragastric*) are given off, and at the lower or apical pole of the body there is a small sense-organ named a *ctenocyst*, together with a nervous ganglion, the latter being one of the first defined appearances of a nervous system in the animal world.

Pleur'odont Lizards, a group of Lizards including those which have the teeth inserted in a groove on the inner side of the jaw. The term is used in contradistinction to 'Acrodon', which is applied to lizards having teeth ossified to the summit or top of the jaw-bones.

Pleurodyn'ia (Gr.) is a rheumatic affection of the intercostal muscles, characterised by an acute pain in the side, aggravated by pressure, and sometimes by coughing and a full inspiration. The pain attending pleurisy is, on the contrary, relieved by pressure. *P.* generally yields to local treatment, such as counter-irritation or blistering. A liniment composed of seven parts of linimentum belladonna and one of chloroform, sprinkled thinly over spongio-piline, and applied to the affected part generally affords speedy relief.

Pleuronect'idæ, a family of *Teleostean* fishes, including the so-called flat-fishes, such as the Sole, Plaice, Flounder, Turbot, Halibut, &c., and belonging to the group *Anacanthini*, in which the fin-rays are soft. The *P.* have no swimming-bladder. Their bodies are much compressed from side to side. The *P.* lie and swim on one side—often mistaken for the belly—which is light-coloured; the opposite side being dark-coloured, approaching the sand in its tint, and thus serving to conceal the fishes. There is a long dorsal and anal fin, and the ventrals are small and jugular in position. The eyes are placed on one side of the head—on the right side in the sole, and on the left side in the turbot. After being hatched the *P.* have an eye on each side of the body, but the bones of the head become twisted, and thus bring both eyes to one side. This condition is an acquired one, a fact proved by the occurrence of the eyes in an almost normal condition in some of the species of the genus *Hippoglossus*.

Pleu'ro-Pneumo'nia. See PLEURISY and PNEUMONIA.

Plev'na, a fortified town in Bulgaria, on a tributary of the Vid, 5 miles E. of the main stream, and 25 S.S.W. of Nicopolis, on the road leading, *via* Lovatz, across the Balkans to Philippopolis. It was an unimportant open town till Osman Pasha (q. v.) surrounded it with entrenched works, and it is mainly remarkable as the scene of the great decisive struggle in the late Russo-Turkish War. Osman Pasha advanced from Widdin with thirty-six battalions and forty-four guns to the relief of Nicopolis, but arriving too late for this object, was allowed, without opposition, to occupy *P.* on the 14th July 1877. Krudener sent Schullder with three regiments against *P.* on the 24th July, only, however, to be repulsed with terrible loss. The importance of the position being at length realised by the Russians, a determined effort to take it at any cost was ordered to be made under Krudener and Schakofskoy. All the available troops were hurled against *P.* on July 31, but the result was a repulse even more disastrous than the first. The two leaders acted independently; Schakofskoy went recklessly forward, while Krudener was unable to give him support. The whole plan of the campaign had to be altered, as a general advance was impossible with *P.* untaken on the flank. A period of inactivity followed, in which the Russians brought up reinforcements, and Osman strengthened his fortifications. Early in September the Grand Duke Nicholas was at the head of 60,000 men, but military critics considered that the task required double the number. After four days bombardment the great assault was made on September 11th, in presence of the Czar himself. It was repulsed with heavy loss at all points except the centre, where the Roumanians took and held the Grivitzza redoubt, and the S., where Skobeleff took two redoubts

from which he had to retire on the following day. This crushing defeat compelled the Russians to turn the assault into a siege, and General Todleben was charged to invest and starve *P.* into surrender. By adroit management on the part of the Turks, large reinforcements and convoys of provisions and ammunition were safely got into *P.* before the investment was complete. But Gourko and Skobeleff, driving the Turks from a line of villages, eventually closed the road to Orkanye, where Chefket Pasha was contributing to the relief of *P.* and providing a retreat for Osman. Not only was *P.* now hemmed in, but the assailants were strengthened by the arrival of the Imperial Guards. Week after week passed, however, and Osman, cut off from the world, held out with heroic firmness, until to hold out longer was impossible. On December 11, he failed in a supreme effort to break through the encircling band in the direction of Widdin, and was forced to surrender with an army reduced by this time to little more than 20,000 men and with sixty guns. The Russian loss has been estimated at 50,000 lives, 25,000 in the September assault alone.

Plexim'eter. See PERCUSSION.

Pley'el, Ignaz, a musician, was born in 1757 at Rupperstahl, a village near Vienna. He was the twenty-fourth child of Martin P., schoolmaster, who observing Ignaz's musical talent, placed him under Haydn, with whom he lived five years. He visited Naples in 1777, where he produced a melodious set of quartetts and his only opera, *Ifigenie in Aulide*. In 1783, he was appointed chapelmaster in Strassburg Cathedral, for which he composed a number of masses. He rapidly became one of the most popular of instrumental composers, and published many duets, trios, quartetts, symphonies, &c. With the proceeds of a professional visit to London in 1791 he purchased an estate near Strassburg. In 1793 he was arrested by the Republicans for supposed aristocratic sympathies, but was liberated on setting a drama in commemoration of the 10th of August to music. He removed to Paris in 1795, and set up a musical publishing business and pianoforte manufactory, which has long been famous. He died November 14, 1831.—**Madame Marie Félicité P.**, widow of Joseph Etienne Camille P., son of the preceding, is one of the most accomplished of modern pianists. See FÉTIS, *Biogr. Univ. des Musiciens* (new ed. 1878).

Plic'a Polon'ica is the term applied to a disease of the scalp in which the hairs become matted together by an adhesive and frequently leud secretion. The odour is exceedingly disgusting, and the matted hair becomes the resort of swarms of pediculi. When left to itself, the disease progresses for about twelve months, when the symptoms subside and the hair returns to its natural state. The diseased mass is pushed by degrees further and further from the surface until it falls off spontaneously, or is cut off by the scissors. *P. P.* is especially prevalent in Poland (hence its name), although it occasionally occurs in other countries. The hair is found, on microscopic examination, to be infested with a fungus of the genus *Trichophyton*. See KÜCHENMEISTER'S *Manual of Parasites* (vol. ii.).

Plinlimm'on, a mountain on the border of Montgomery and Cardigan counties, Wales, about 12 miles from the coast, and in the centre of a wide expanse of moorland. It has three peaks, the chief of which is 2481 feet high. Its name (Cymric *Pumlumon*, 'five rivers') points to the fact that it is the source of five streams, of which by far the most important are the Severn and Wye. From the recesses of *P.* Owen Gendower made raids on the English marches.

Plinth (Gr. *plinthos*, 'a brick'), in architecture, the square slab forming the lower part of the base of a column; also the plain projecting band at the bottom of a wall. In Classical and Gothic buildings the *P.* is sometimes divided into two or more gradations.

Plin'y (C. *Plinius Secundus*), commonly called *P.* the Elder, famous as the author of the *Historia Naturalis*, was born 23 A.D. whether at Verona or Novum Comum is uncertain. The latter, however, seems on the whole to have the best claim, and that mainly from the facts (1) that the family of the Plinii belonged to Comum; (2) that the estates of *P.* were situated there; (3) that the younger *P.* was born there, and (4) that numerous inscriptions relating to members of the family are to be found in its immediate vicinity.

History affords us but a meagre record of the events of P.'s life, but the account which the younger P. has left of his uncle's habits goes some way to fill up the blank. P. came to Rome when young, the scion of a distinguished family, furnished with ample means for securing instruction from the ablest teachers of the time. At the age of twenty-three he went to Germany under L. Pomponius Secundus, of whom he afterwards wrote a memoir. While there he was appointed commander of a troop of cavalry (*præfectus alæ*). He travelled over most of the German frontier, and in the brief intervals of rest snatched from the duties of a soldier's life composed his treatise *De Juculatione Equestri*. At the same time he commenced his history of the Germanic wars—afterwards completed in 20 books—a work which he dreamt he was commissioned by Drusus Nero to undertake. In 52 A.D. he returned to Rome with Pomponius and began to study jurisprudence. As a pleader he was not distinguished. The greater part of Nero's reign he spent in retirement. His work entitled *Studiosus*, an educational treatise in three books, and his *Dubius Sermo*, a grammatical work in eight books, were written about this time. Towards the close of Nero's reign he was made procurator in Spain. Here, in A.D. 71, on the death of his brother-in-law, P. was left guardian of his nephew. During his absence he intrusted the boy to the care of Virginius Rufus and adopted him on his return. Vespasian was now emperor. P. had known him in Germany, and was at once received into the imperial circle. There is no evidence, however, that he was created senator by Vespasian. At this time, probably, he completed the *Historia* of Aufidius Bassus. P.'s manner of life affords a wonderful example of perseverance and assiduity. We are indebted to his nephew for an interesting sketch of P.'s mode of living. It was his custom to spend a portion of the night in study by candle-light, in autumn, beginning at a late hour in the evening; in winter, at one or two in the morning. Before dawn he visited the emperor, and after executing what commissions he might receive, he returned home and resumed his studies. He then partook of a slender meal, and in summer would lie in the sunshine and listen while some book was being read to him, making notes and extracts all the time. Then followed in succession a cold bath, a frugal repast, a short sleep, a period of study; thus passed the day till dinner time (*cena*). During dinner some book was read to him, on which he commented from time to time. Such was his mode of life in the city. In the country his time was almost wholly devoted to study, the bath being his only relaxation. When travelling he was accompanied by a secretary with book and tablets. In winter he compelled his scribe to wear gloves that his writing might not be impeded by the cold. By this ceaseless application to study, persevered in all life long, he amassed an enormous amount of materials from which he compiled his *magnum opus*, the *Historia Naturalis*, which alone of his works has survived, and on which his fame chiefly rests. It treats of an almost endless variety of subjects, and is in fact a much more comprehensive work than its title indicates. Everything that came in P.'s way found a welcome place in his treasure-house. When the younger P. describes his uncle's work as *opus diffusum, eruditum, nec minus varium quam ipsa natura*, he is very near the mark. It consists of 37 books—the first containing a dedication of the work to Titus, and a table of contents of the remaining books—and embraces, so says P. in the preface, 20,000 matters of importance drawn from about 2000 volumes. It was impossible that such a compilation should possess much scientific value. P., with all his insatiable appetite for accumulating knowledge, was destitute of genius: he was not an original observer; he was simply a bookworm. His work is a magnificent monument of industry and research, all the more wonderful that it was reared amid the distractions of official life; it is even more: to scholars it is a work of inestimable value as supplying details on subjects that would have otherwise remained unknown. It was published 77 A.D.

The circumstances of P.'s death were singular. He had been appointed admiral, and in 79 A.D. was stationed with the fleet at Misenum. Seeing a cloud of pine-tree form rising from the top of Vesuvius, he went to a spot whence he could get a better view; got a light vessel ready; embarked; and took his tablets with him. He then proceeded to the point of danger. Hot cinders fell all round. Eager to examine the phenomena more closely, he landed at Stabiae, where he was suffocated by the vapours. All his attendants escaped. The *editio princeps* of P. was published at Venice in 1469, fol. The best

critical editions of the text are those by Sillig (Leips. 1831-36) and L. v. Jan (Leips. Tübingen, 1854-1865). The French translation by Ajasson de Grandsagne, published by Panckoucke (Paris, 1829-1833) in 20 vols., is enriched by many valuable notes by Cuvier, Letronne, and other eminent men of science and letters. To enumerate the translations would be superfluous: the *Historia Naturalis* has been reproduced in almost every European tongue.—P. (C. Plinius Cæcilius Secundus), generally called P. the Younger, was the son of C. Cæcilius and Plania, sister of the elder P. He was born at Comum on the *Lacus Larius* (Lake of Como) 61-62 A.D. His father died young, leaving his son, a boy of nine years, to the care of his uncle, who adopted him; and who, with his mother and Virginius Rufus his tutor, bestowed great pains on his education. So apt a scholar did he prove that at the age of thirteen he wrote a Greek tragedy. He studied eloquence under Quintilian and Nicetes Sacerdos, and soon acquired the reputation of being one of the most learned men of his day. In his nineteenth year he made his first appearance in the forum, and his oratorical ability secured for him frequent employment as an advocate before the court of the Centumviri and in the Roman Senate. While still young he served as tribune militaris in Syria; was quaestor Cæsaris 89-90 A.D., tribune plebis 91-92 A.D., prætor 93-94 A.D., præfectus aerarii militaris 94-96 or 95-97 A.D., præfectus Aerarii Saturnii 98-100 or 101 A.D., Consul suffectus with Julius Cornutus Tertullus 100 A.D., Augur 103 or 104 A.D., curator of the channel and banks of the Tiber 105-107 A.D., legate and proprætor of Pontus and Bithynia 111 and 112 or 112 and 113 A.D. P. died before 114 A.D., either in his province or soon after his return. He was in his eighteenth year when his uncle perished 24th August 79 A.D.; he must therefore have died about fifty-two. P. was thrice married; twice under Domitian (ad. Traj. ii. 2), and lastly to Calpurnia (Epist. iv. 19). He had no issue by any of his wives. The chronology of P. is by no means settled. The above dates (Mommson's) are taken from Teuffel's *Geschichte der Römischen Literatur*, sect. 335.

The extant works of P. are the *Panegyricus* and *Epistole* in ten books. The former is a pompous and fulsome eulogy on Trajan, but of some value for the information it contains about the writer and his times. The *Epistole* are a most agreeable collection of letters, and hold a high place in this kind of literature. They contain, moreover, much interesting information regarding P. and his contemporaries. P. was scholarly, genial, and liberal, and he approaches more closely than almost any other character in ancient literature to the best modern ideal of a 'well-bred, cultivated, and blameless gentleman.' The *editio princeps* of the *Epistole* published at Venice 1471 contained only eight books. The first complete edition was the Aldine (1508). The best critical edition is by Keil and Mommsen (1871). Translations are numerous. See also Church and Brodribb's 'P.' in *Ancient Classics for English Readers* (Blackwood, Edin. 1870-78).

Pliocene Period is the third and highest member of the Tertiary Period. Above 50 per cent. of its fossil shells are existing species. The formations belonging to this age are of small development in Britain, being met with only in Suffolk and Norfolk, where, spreading over the Lower Eocene, they overlap the Chalk. Three groups are distinguished—(1) *The Coralline Crag*, a series of soft, marly, whitish sands, sometimes speckled with green, containing occasionally thin bands of limestone. Of the 350 species of marine mollusca, about 30 per cent. are extinct. (2) *The Red Crag*, a group of beds of red sands and gravel, with accumulations of rolled shells. It is usually found side by side with the Coralline Crag, though here and there in hollows of the latter portions of it exist. Of its 256 marine shells 25 per cent. are extinct. (3) *The Norwich Crag*, a series of beds of sand, gravel, and loam, which contain a mingling of marine, freshwater, and land shells, with bones of several extinct mammals. There is evidence of the beginning of that severity of climate which attained its climax in the glacial period. Pliocene formations are found in Belgium, in Italy flanking the low heights of the Apennines, in Sicily covering nearly one-half of that island, and in S. Russia round the coasts of the Caspian and Aral Seas, and the N.-western shores of the Black Sea.

Plocaria, or more properly *Gracilaria*, is a genus of red-spored Algae belonging to the order *Sphaerococcoidæ*, and includes the so-called Corsican moss and the Ceylon moss. The first was

formerly in repute as a vermifuge, but this repute had probably no more solid basis than the doctrine of signatures, the cylindrical stems and branches bearing a fancied resemblance to a worm—*therefore*, it was argued, an effective remedy for worms (see MEDICINAL PLANTS). If genuine, it should consist of *P. Helminthorrhodon*, but other species are substituted or mixed with it. *P. amida* is exported from Ceylon as an article of food. It furnishes a useful jelly for invalids and children, possessing considerable nutritive qualities. The Chinese manufacture it into a sweetmeat.

Plocéus. See WEAVER-BIRD.

Plock (Russ. *Plotzk*), a government of Russian Poland, bounded N. by Prussia, and S. by the Vistula. The surface in the N. and near the Vistula and Narev is elevated, but in general it is very level, and largely covered with lakes, marshes, and forests, the last occupying half of the whole surface. More than half the soil is arable, and 15 per cent. is excellent meadow pasture. P. had, in 1873, 204 factories, including distilleries, breweries, tobacco, soap, sugar, and candle manufactories, employing 1433 men, and yielding produce to the value of £145,067. Area, 4200 sq. miles. Pop. (1872) 485,792.—**P.**, capital of the preceding, lies on the right bank of the Vistula, 78 miles W.N.W. of Warsaw. It has a cathedral, founded in 968, 4 other churches, a theatre, and the palace of the bishop. There is considerable export trade by the Vistula, chiefly of wood and corn. Pop. (1870) 21,823.

Plojes'ti, a town of Roumania, on the Dimbow, a sub-affluent of the Danube, 33 miles N.N.E. of Bucharest by rail. It is embowered amid gardens and groves, and has some trade in grain, wool, &c. During the Russo-Turkish War (1877-78) it was for some time the headquarters of the Russian Emperor. Pop. (1870) 26,468.

Plongée, in fortification, the exterior slope of a parapet, which serves to support the weapons of musketeers, so as to direct their fire. The slope varies from 1 in 4 to 1 in 9, but in English fortification is usually 1 in 6. The P. should be flat enough to admit of sand-bags being ranged on it, to protect the defenders.

Plotinus, the Father of Neoplatonism (q. v.), was born at Lycopolis in Egypt, about 203 A.D., studied philosophy under Ammonius Saccas (230-41), and, wishing to gain an insight into the doctrines of the Persians and Indians, accompanied Gordianus on his Mesopotamian expedition (242-44). He narrowly escaped sharing the emperor's fate, but gaining Antioch passed on to Rome, where for five-and-twenty years he continued to lecture; Porphyrius, Longinus, and Amelius being amongst his hearers. The most striking feature of his uneventful life is its gnostic and ascetic element. To friends who asked him to sit for his portrait he answered that it was bad enough to have to wear a shadow, without making a shadow of a shade. He ate no animal food, abstained from baths, refused a physician in his last sickness, and so died at Puteoli in Campania, about 270 A.D. There glided, says Porphyrius, a dragon from under the bed of the dead philosopher, whom the Delphic oracle in limping hexameters declared to have been 'good and gentle, benignant exceedingly, and pleasant in all his conversation.' Amid much confusion and repetition may be discovered in P.'s writings the leading idea of an absolutely perfect being, willing to shed its goodness on all who seek for it. He saw a divine element in the philosopher, who is 'ready by nature, furnished as it were with wings, and not needing to sever himself from matter like the rest, but predisposed to things above; in the lover, whose innate dreams of loveliness raise him towards the one incorporeal beauty; and, in a less degree, in the 'musical' man, with his passive appreciation of the beautiful. The common herd, however, wallowing in a slough of worldliness, of them the divine desire could hardly take account. This absolute goodness, therefore, indifferent to the misery and debasement about it, must differ widely from the goodness of men; virtue could not be predicated of the divine, but was merely a means towards the attainment of that final goal whose nature generations of philosophers after P. set themselves vainly to discover. P.'s guide and master throughout is Plato, whom he quotes with a reverential *ipse dixit*. His fifty-four treatises were arranged by Porphyrius, according to their subject-matter, in six *Enneads*, or sets of

nine (Gr. *ennea*) books. A Latin translation of them by Macceilius Ficinus was printed at Florence in 1492, to which the Greek text was added (Basel, 1580), the best modern editions being those of Creuzer (3 vols. Oxf. 1835), Kirchoff (2 vols. Leips. 1854), and Dübner (Par. 1855). There is a translation of the complete *Enneads* into French by Bouillet (3 vols. Par. 1857), and of selections in English by Taylor (Lond. 1834), in German by Engelhardt (Erlang. 1820). See Kirchner, *Die Philosophie des P.* (Halle, 1854); Kingsley, *Alexandria and her Schools* (Camb. 1854); Richter, *Ueber Leben und Geistesentwicklung des P.* (Halle, 1864); and Grucker, *De Plotinianis Libris qui inscribuntur 'Peri tou Kalou' et 'Peri tou noëton Kallous'* (Par. 1866); and Lewes, *History of Philosophy* (Lond. 1867).

Plotus. See DARTER.

Ploughs and Ploughing. Ploughing is an agricultural operation by which the naturally rough and hard surface of the soil is broken up, and prepared to receive the seeds of various plants; ploughs are the implements or mechanical appliances by which this operation is performed. In ploughing, the surface is turned over in something like regular slices, and at an angle more or less uniform. The hollow parts between the ridges form beds into which the seed falls when scattered over its surface; the seed being afterwards pressed down and finally covered up by an implement drawn over the surface (see HARROW), which reduces the projecting parts to a level surface more or less uniform.

The plough passed through a great number of stages before it acquired its present highly scientific form. Its origin is unknown, although frequent mention is made of it in the earliest records of history, both sacred and profane. Rude representations of it are found on the painted walls of Egyptian tombs and in the pages of the most ancient illuminated MSS. Some classic writers have described it minutely. It may be safely conjectured that, from a very early period, man would perceive that the sowing of his seed would give better results in the way of crops when the soil was in some measure opened up than when the seed was simply strewn on its original surface, which, under the most favourable circumstances, would be anything but free and open, but under the most unfavourable would be close, hardened, and baked—a condition that would be most frequently met with under tropical suns and rainless clouds.

Passing over the rudest and most primitive forms of the plough, it may be noticed that an Egyptian monument furnishes a sketch of one that shows some approach to the parts of the modern implement, in so far as there is what might be really called a well-shaped share or sock, with two handles fitted into its back part, while a beam is also provided, to which the animal-power dragging the implement is yoked.

There is a plough used in India at the present day, and known as the 'Caatikal,' in which the wedge-shaped form of the modern mould-board is perhaps more nearly approached in its sock or share. It is pointed, with a slight curve downwards, while the beam passes through an aperture made in the upper and back part of the share. Outside of the share a small vertical handle is fixed to the beam, in order to regulate the depth to which the sharp and pointed end of the sock shall enter the soil.

In a Chinese plough we find the share still more pointed, and gradually swelling out towards the back to a considerable breadth, the other side being in a straight line. Thus in fact gives almost the exact form of the share of a modern plough. To the back part of the share a small and short piece of timber is fixed. This provides a point of support for two vertical uprights, the hinder of which is much longer than the front one, and acts as a lever by which the depth to which the share enters the soil is regulated.

Another East Indian plough exhibits a still nearer approach both to the parts and the general arrangement of the modern implement. The share for a considerable length of its base is horizontal, the back sloping at a considerable angle upwards, while the front sweeps from the narrow point at front to the hinder part at the back in a well-designed curve. The beam, which is of considerable length, projects forward in a double or ogce curve, the outer end of which is at a greater elevation than the inner. This is fixed to the upper part of the share, while a handle at the back serves to regulate the depth to which the share penetrates the soil.

In a particular form of Mexican plough, the modern mould-board is still more closely approached in its share. The sole or base of this is horizontal, while the front is sharpened to a dovetailed form from which the share gradually rises to a part parallel to the base. To the extreme end of this upper part the one stilt or handle is dovetailed, and to the front of this is secured the end of the beam; which is further strengthened by a small vertical upright rising from the upper side of the share.

The only Roman plough of which drawings or sculptured representations have survived is one showing the form used in the time of Tarquin. It was shaped like the letter Γ , the ends of the T being sharp pointed, while the tail, rising upwards at a sharp angle, formed the beam. The soil was stirred by the lower sharp-pointed end, while the depth to which it entered was regulated by the ploughman pressing in or lifting up the upper end, while the implement was dragged through the soil by oxen attached to the end of the beam.

What was known as the *caschrom*, one of the earliest British ploughs, was more like a spade than a plough. The fore part was a flat, duck-billed part, somewhat like a chisel in shape, and attached to a handle which rose at a considerable angle from the front. This implement, rude though it be, is to some extent used even yet in the extreme northern parts of the kingdom, we ourselves having seen it, more or less modified, in the Shetland Islands. In one of the Harleian MSS. there is the figure of a plough in which the share is formed of a rhomboidal piece of timber attached to the lower end of a vertical part, the upper end being cleft, so as to form two handles. This cleft part passes through a flat board, which passing forward forms at its extremity the part to which the cattle were yoked. All the implements of what might be called strictly British or insular origin, had only that part of the modern plough which is known as the share. None had the double wedge known as the mould-board. It was to the Low Countries that this great improvement is owing. Long known as the 'Rotherham' (probably a corruption of Rotterdam), the plough introduced into England from the Low Countries possessed all the peculiar features of the modern plough. It was that on which succeeding ploughs were formed, and the first patent taken out was one granted to a Joseph Coljame, of Yorkshire. Jethro Tull, to whom English agriculture is vastly indebted, if for nothing else than his system of 'dull' husbandry, invented a form of plough designed to aid this, but it was too complicated to be of general utility. Little or nothing was done after Tull's attempt, except to improve the Rotherham plough, and even in this way little was done, till a Scotch mechanic, James Small, constructed one upon scientific principles. In Small's plough we meet, indeed, with nearly all the parts of the modern plough; and succeeding makers took his implement as their model.

Ploughs may be divided into three kinds, the 'swing,' the 'wheel,' and the 'turn-wrist,' with sub-classes which shall be noticed in due course. The first of these is chiefly used in Scotland and the northern parts of England; the 'wheel' in England, although its use is becoming more and more extended in the former country. The 'turn-wrist' is almost purely local—a district plough, in fact—being used chiefly in Kent, although a modification of it is employed on very steep inclined land, where the furrows have all to be turned in one direction to save the long turnings at the 'hull-lands.' The illustrations in Figs. 1 and 2 will enable the reader to understand the various parts of the 'swing' or 'wheel' ploughs. We shall describe the swing first, taking what we may call the active parts of it, as the 'mould-board,' *a a* Fig. 1, the 'sock' or 'share,' *b* Fig. 1, and the 'coulters,' *c c*. In ploughing, the cutting of the slice from the original soil takes two directions, the vertical and the horizontal. The vertical cut is done by the coulters (see *c c*, Fig. 1), the horizontal by the sock or share (see *b*, Fig. 1),

while the slice so cut is turned over and placed at a certain angle by means of the mould-board. See *a a*, Fig. 1. The

coulters (*c c*, Fig. 1) is in fact a strong knife secured to the frame of the plough, in such a way that its angle in relation to the plane of the land-surface can be adjusted as required. On the land side it is flat, while on the furrow side it is rounded, or tapered on the back in order to give the necessary strength, with lightness. The angle at which it is placed in relation to the beam of the plough is generally about 55° , but this varies according to the work to be performed. The share (*b*, Fig. 1) is placed at the fore part of the sole, on which the plough slides along the soil. In English ploughs it is made of cast iron, the under part being case-hardened to about the thickness of the sixteenth of an inch; the remainder being left soft or in its usual condition. This system, the invention of Robert Ransome, of Ipswich, enables the share to keep up always a sharp-cutting edge. The pitch or inclination of the share is made to vary, according to circumstances, so as to sink deeper into, or to rise out of, the soil; or, as it is technically stated, to take more or less land. The coulters are also capable of adjustment, so that it may receive from or approach to the land side as required. These may be called the active parts of the plough, as they in reality do the ploughing, the other members forming the part of carriers, by which the active parts are retained in their places and adjusted as circumstances may require.

It is generally considered that the mould-board plays the most important part in the operation of ploughing. But although it is a highly important member, still the coulters and the sock or share exercise an important influence in the formation of the furrow-slice. This has not merely to be severed from the general mass of soil and turned over at a certain angle, but to be so adjusted that the largest bulk of soil be exposed to the action of the atmosphere. The form of the furrow-slice has been a subject of great contention amongst plough-makers. Some maintain that it should be broken up and more or less pulverised (the angular form however being still retained), while others insist upon the slice being turned over 'in a perfectly straight line, not only unbroken but even and uncracked.'

As has been stated, it is upon the form or contour of the mould-board that the majority of writers and makers of ploughs maintain that these conditions of soil depend; but, on the other hand, this form must itself be determined to some extent by the character of the soil. Thus, in what may be termed short soils, having little cohesive properties, a mould-board with a convex contour and comparatively short length will give the broken condition of soil referred to, while in stiff and cohesive soils it will not. It is indeed from the general nature of the soil that short and convex mould-boards have been generally used in Scotland, and the converse in England. In practical ploughing, a very good test as to whether the form of mould-board suits the soil in which it is used, is the fact of the soil becoming uniformly bright all over its surface. If, on the contrary, it is brightened at one point and left dull at another, it may be safely inferred that the plough is not suitable for the soil.

We now proceed to consider the various methods in which the parts of the plough operate, taking first the mould-board. This may be considered as a long wedge, with its outer surface screw-shaped. When dragged through the soil, it partially severs it from the mass, and as it passes along turns it over at a determinate angle, the thickness and breadth of the severed soil, technically called the furrow-slice, being dependent upon circumstances, but average size, being 10 inches by 7, or 6 by 9. The best angle for turning over the furrow-slice is found to be 45° , thus burying the weeds, &c. which form the original surface, and exposing the largest bulk or mass of soil to the action of the atmosphere. The diagram (fig. 2) illustrates the way in which the mould-board turns over the furrow-slice. In this *a b* shows the breadth of the slice as cut by the coulters entering near the point *c*, the mould-board turning over and depositing the furrow-slice in the position *d e f g*. The side *c g* corresponds to that originally lying against the land, forms, as shown in the diagram, the flat or upper side *d g*, while that cut by the share or original bottom part, as *d b*, takes now the position of the flat or upper side *d e*, while *f g*, which originally formed the upper or grassy surface, is laid in contact with the side *g d* of the furrow-slice turned over before. It will be seen how, by this process, the grass and weeds are buried. The lower part of the diagram shows the positions which the furrow-slice assumes in being turned over, *a b c d* being the form of slice before being operated upon, as the

coulter cuts the end *a c*, and the share the bottom *c d*, it is turned over by the twist of the mould-board, somewhat as

shown at *h h*, in the upper diagram in Fig. 2. The next position assumed is the vertical, as *d i j k*, the last being *k l m n*.

The 'wheel' plough varies in a very trifling degree from the swing plough, the main difference being that the one has wheels, and the swing plough, as in Fig. 1, has none.

The next plough we have to notice is that of the 'Subsoil.' Between forty and fifty years ago Lord Pomerville took out a patent for a double-furrow plough, which excited great expectations as to the economical work it was to perform. It was obviously a great gain, if by the same power double or even a half or a third more work was obtained. But from inherent defects in the plough, the expectations raised by it were not realised. The idea, however, did not die out. About ten or twelve years ago Mr. Price of Aberdeen patented a double-furrow plough which solved the difficulty. Its principal peculiarity was placing the wheels at an angle to, not parallel with, the surface of the soil, the periphery of the wheels being also angular, not parallel-faced. This plough was bought up by the firm of Messrs. John Fowler & Co. of Leeds, who introduced several improvements into it, and made it a complete success. Other forms were brought out by the Messrs. Howard of Bedford, the Messrs. Ransome, Sims, & Head of Ipswich, Messrs. Murray & Co. of Banff; and now the double-furrow plough is an established implement, capable of doing high-class work, and at a large saving of power. The forms of implements of this class vary much in point of arrangement and mechanical detail. In those made by the above firm, the one mould-board is in advance of the other, each having its coulter, but as in the case of the steam-plough there is no share, properly speaking; its place is supplied by a strong curved line, connected to the frame above at one end, and at the other to the mould-board about the middle of its length and height. The general frame is supported by two wheels, the largest of which is at the back, between and near the ends of the stilts or handles; the smaller about the centre, a little in advance of the coulter of the back or second mould-board. A land not furrow wheel is provided in front; and one capable of adjustment as regards depth is by a lever carried back between the stilts to be within reach of the ploughman.

The 'Subsoil Plough' is designed to stir and break up the lower soil which lies beneath the working range of the ordinary plough. The simplest form takes us back to primitive times, for it is simply a share attached to a vertical stem, connected with the beam to which the power is yoked. The first practical improvement was introduced by Smith of Deanston; this was greatly improved by Reid, who added wheels, and gave the power of regulating the depth to which the implement could be worked. In the most improved form of Reid's subsoiler, as made by Howard, the share or tine is

of strong wrought iron, firmly bolted overhead to the cast-iron beam. The form of the tine or subsoiler is somewhat like that of the letter L, with the angular or corner part filled in with a curved feather, but provided with an aperture which gives lightness along with the necessary strength. The frame has two stilts or handles—the left-hand one carries a small wheel, while two wheels run in front near the bridle. A 'double subsoiler,' on the same principle, gives the power of working two times with a draught not greatly exceeding that required by one. When the subsoil plough is used not only to stir the lower soil but to bring it to the upper surface, it is termed a 'trench plough,' or a 'subsoil trench plough.'

The 'Broadshare Plough,' the invention of Mr. Bentill of Maldon, is an important and useful implement. Its main object is to get rid of the surface weeds, while it stirs the soil to a greater or less depth as required; it can indeed be so arranged as to work as a subsoiler. The working parts are shares, three or more in number, of great breadth; these are preceded by an equal number of what are called 'points,' arranged parallel with each other, the centre point preceding the others. This arrangement enables the hardest soils to be penetrated, and the implement to work with a steadiness not otherwise obtained.

The 'Turn-west or wrist,' the 'Kentish,' or 'the one way furrow plough,' is, in detail of arrangement, a complicated and a heavy, clumsy-looking implement, but in the principle of its operation it is very simple. Its object is to turn the furrows all in the same direction, that is to be over at the same angle. Two mould-boards, so called, being merely pieces of board broader at one end than the other, and rounded on the upper surface, are placed so as to form a triangle, the narrow parts of the boards being placed behind the shares at this point; they are so jointed that in going in one direction, say towards the S., the mould-board, which turns the slice to the W., is thrown over in going N., becoming the side plate, the operation bringing down the other mould-board, which turns the furrow still to the westward. In this way all the furrows are turned in one direction over the whole surface of the field. The changes of the mould-boards in the Kentish plough necessitate of course a change in the direction of the point of the coulter, so that its point shall coincide with the corresponding point of the mould-board. The Kentish plough, nevertheless, does most efficient work, and is greatly esteemed in its own special district. A favourite form long in use was that of Wilkie's, and a still more recent form is that of Locock's, manufactured by Ransome, Sims, & Head; but the most recent of all, and the most improved, is that of Davy of St. German's, Cornwall, which combines almost nearly every requisite for the operation, applied with the highest mechanical skill in the design and construction.

Ploughing.—We have already, in describing the action of the mould-board, so far explained what ploughing is in the action of this and the attendant parts; but the reader may have noticed, in looking at a newly-ploughed field, before the furrows were disturbed and the surface made smooth by the action of the harrows, that the furrows lay in a certain way. Part lie in one direction and part in another, the two sets meeting in a central point. From this to right and left there are only so many furrows. The number of those lying towards the right, and those towards the left, together make up what in England pretty generally is called a 'stretch' or a ridge. The field is divided into a certain number of those 'stretches,' between two of which a deeper part generally called a furrow is made, this in olden times constituting the only way in which the land was drained. These 'stretches' or breadths are rarely ploughed flat but convex, the point at which the two sets of furrow-slices meet, one lying to the right and the other to the left, forming the crown of the 'stretch' or ridge. Each furrow is laid over at an angle of 45 degrees, and the next furrow is turned over so as to cover only a certain portion of its surface, thus forming a series of angular seed beds. The best length of furrow is found to be an average of 250 yards, this being the distance that a pair of horses in good average working condition can take at one stretch without stopping and without being over-fatigued.

We cannot conclude the subject of P. and P. without alluding, however briefly, to steam ploughing. So far from being a thing of yesterday, it dates from a period not far short of 150 years ago. The practical period of the system may, however, be said

to have begun some five-and-twenty or thirty years ago, and it is now one of the established facts of agricultural engineering. In considering the application of the power of steam to the preparation of the soil, we must not lose sight of the fact, that steam ploughing is not the same thing as steam cultivation. We shall take up the subject of steam ploughing first. The most important, and indeed the type upon which all or nearly all the modifications of other inventors are founded, is the 'Balance Plough,' the invention of John Fowler. The introduction of this was the turning-point in the practical working of the system. Let the reader conceive of a frame, bent at its centre at equal angles, so that the two ends tilt up as it were when the central part is running free, on two large wheels. Each end of the frame is provided with three or more (generally four) plough bodies or mould-boards, all converging towards the central wheels. These bodies have no soles, but simply coulters and shares; in passing through the soil, therefore, they do not form the hard pan which is so objectionable a feature in the working of the common plough, with its solid blade or sole. This arrangement of the plough as a whole obviates the necessity to turn the implement at the end of each 'bout' or journey, for all that is necessary is simply to tilt on the central shaft the one end into the air, which has been engaged with its plough-bodies in turning over the soil say from S. to N. This operation at one and the same time lowers the other or opposite end of the frame, bringing the plough-bodies into contact with the soil, and in such a position that they are prepared to take the return journey from N. to S. As to the means employed for working the plough to and fro, Messrs. Fowler prefer what they call the direct system. In this two steam engines are used, one being placed at one, the other on the opposite side of the field. By a peculiar system of windlass, the plough is dragged to and fro between the engines, by means of a steel wire rope attached to it. It will be obvious to the reader that in order to plough the breadth of the field, the whole apparatus, as thus set down, will have to be moved transversely in proportion as the ploughing proceeds. This is effected by arrangements which, like all the others, are characterised by the highest mechanical skill and constructive excellence. As the steel rope, in consequence of its length, rubs against the soil in passing to and fro, it is supported by and runs upon light pulleys running on frames. These are placed at intervals across the field, and are changed in position as the ploughing proceeds.

Messrs. Howard of Bedford, the other most widely known makers of steam cultivating apparatus, advocate what is known as the 'roundabout' system. In this only one steam-engine is used, and it may be set down without the field, if more convenient, as well as within it. The engine works a windlass for winding and unwinding the steel wire rope, and the plough is dragged to and fro between two anchors, arrangements being made for moving these across the field as the implement ploughs it. As the name indicates, the rope working the plough may be said to encircle the field, or go round about it according to its form. The rope in the first instance proceeds from the main windlass next the engine to the anchor, say in the furthest corner of the field. From thence it passes in a straight line to the second anchor, between which the plough works. From the second anchor the rope returns to the main windlass. Wire porters are used to keep the steel rope from the ground as in Messrs. Fowler's system. The Messrs. Howard have introduced into their system many highly ingenious arrangements. Various other makers have brought out systems varying more or less in mechanical detail, but characterised by the general features of the plans of the leading makers we have named.

In steam cultivation the soil is prepared for crops entirely by means of an implement called a grubber or cultivator. Mr. William Smith, of Woolston, near Bletchley, was the introducer, as indeed he may be said to be that of the roundabout system we have described, and by means of which he worked the grubber to and fro across the field. One great difficulty with which all makers and users of steam cultivating apparatus have to contend are the breakages to which they are so liable. Unless the drivers of the engine are particularly careful, the huge and heavy apparatus may be brought into collision with the engine; and not only this, but the breakages from ropes, and from the plough-bodies coming in contact with stones and boulders in the soil, and other parts, are constant sources of annoyance and loss.

To prevent the plough coming in contact with the engine, or proceeding too far on its journey, Messrs. Barford & Perkins, of Peterborough, have recently introduced a very effective form of self-acting apparatus, which makes it impossible for this accident to occur.

P. and P. in other Countries than Great Britain.—In Europe the only country whose ploughing implements merit notice is Flanders, which has long been celebrated for its farming, and which has given to other countries not a few of their most useful crops, and some of the most successful and striking of their methods of cultivation. It is often cited as 'the home of spade husbandry,' to which the remarkably high condition in which the soil is kept is said to be owing. While, however, the spade is used, and in some districts—for example, the Pays-de-Waes—extensively, the plough is nevertheless the principal implement employed in cultivating the soil. To those examining for the first time the condition of the splendidly cultivated Flemish fields, and the luxuriant crops which they bear, the natural impression is that the implements used to bring about such results must be of the highest class as regards design and construction. This, however, is not the case; for not only are they small in number, but the construction is simple and even rude.

Let us begin by a brief examination of the plough. Constructed wholly of wood, with the exception of those parts of iron necessary to hold the whole together, and generally, but not always, a covering of wrought iron to protect the face of the mould-board, the various parts are heavy and clumsy in the extreme. The most marked feature is the single stilt or handle with which the implement is provided. This is secured to the end of the beam, and is provided with a slight curve outwards. Within a few inches from the upper end of the stilt a small handle projects in a direction opposite to that in which the plough works. This handle resembles in form, and is somewhat about the length of, the horn of a short-horned cow. It is used to guide the plough and turn it at the end of its 'bout' or journey. It is preferred by the Flemish ploughman to a double-stilted implement, as it enables him not merely to work the plough with great ease, but also leaves his other hand at liberty to use the long iron tool by which he keeps the mould-board and coulters free from weeds. A few inches in advance of the lower and perpendicular part of the stilt or handle a vertical bar is morticed into and descends from the beam. This, together with the lower part of the stilt, supports the mould-board, which is further tightened and secured by an iron stay. The mould-board is generally constructed of timber built up in sections, and made to assume a short, abrupt, convex contour. Rude as this part of the plough appears, it lays over the furrow-slice easily with the land side cut square and clean. The sole is remarkably level and free from the alternate elevations and depressions which disfigure the working of even some of our ploughs which have a high reputation. The coulters are very different in form to that of our English ploughs, presenting somewhat the appearance of a spade cut in two, but in a vertical direction. It is adjusted by a simple wedge. The beam is horizontal—that is, parallel or nearly so with the surface of the soil—and its peculiar feature is a wooden shoe, placed near its extremity and slightly behind the bridle. This shoe, which is shaped exactly like the well-known wooden sabot of the Continental peasant, is designed to serve the purpose of the wheel—land or furrow—of our plough. It serves, however, another important purpose, of breaking the clods, getting rid of the weeds, &c. out of the way of the coulters and mould-board, and also performs, in some respects, the office of the 'skim coulters' of the best form of English ploughs, such as that of Howard's. The bridle is of iron, and of simple construction. Rough and unwieldy as the old plough is, it is nevertheless surprising how excellent is the work which it performs. It swings freely, moves along with great precision, lifts the furrow-slice well up, turning it over regularly at the usual angle of 45°, and, as we have stated, gives a sole very uniform.

The United States of America have done very much to improve the plough, by investigating the principles on which it operates, and endeavoring to discover a method or series of rules according to which the best form may be decided on. From a very early period in the history of that country, this work of practical investigation began. Jefferson, the well-known President, was the first, so far as we know, who attempted to discover a mathematical or geometrical principle by which the lines of the

mould-board could be set down, and in such a simple way that any mechanic who had but even a very general knowledge of drawing could avail himself of it. Mr. Jefferson drew up a paper explanatory of his system for the French Institute, and although he did not succeed in discovering a system generally applicable, the art of plough-making is vastly indebted to him for stating very clearly certain general principles of considerable practical value. His system of *lines* failed to secure all he aimed at, but it enabled any mechanic to construct a mould-board which, at least, was of the form deemed the right one by Mr. Jefferson. This, certainly, was a great advance in the mechanism of plough-making. For up to his time no fixed principle of design had ever been attempted, so that, however eminent any individual maker was, the secret of his success died with him. Space prevents us from pursuing further the history of American plough-making, interesting and useful as such an investigation would undoubtedly be.

As regards the art of ploughing, English agriculturists as a general principle maintain that ploughing should be done on such a system as to turn over the furrow-slice with a uniform surface, and with a mass of soil unbroken and compressed; Americans hold an opinion precisely the reverse. Various reasons have been suggested for this divergence of opinion. Perhaps the most obvious is that the soil is different, and that in consequence of the number of roots of trees left in the ground from the forest-covered condition of the soil, a short, abrupt mould-board is necessitated. But it cannot be the wholly true one, inasmuch as a large portion of the land is prairie, not forest-covered. Whatever the reason originally, recent discussions among the first American farmers show that they put the matter on a much more philosophical basis; namely, that the proper condition in which to leave the soil is that in which the atmospheric influences will be best able to act upon it. We do not mean to insist, of course, that all American ploughing is done upon this system, the influence of the English system having more or less extended to America; still it may be accepted with safety as the characteristic of the ploughing of the United States, and is, moreover, from the high position and great practical influence of those who advocate it, likely to become more and more so.

Ploughgate of Land is a term of Scotch law denoting, it is supposed, 100 Scots acres. It is the qualification of property to kill game under the *Game Laws* (q. v.).

Plover (*Charadrius*), a genus of *Grallatorial* or Wading Birds, forming the type of a family and sub-family. It is distinguished by having a short strong bill. The hinder toe is wanting, and the first quill is the longest. The tarsi are long and slender, and the outer toe is larger than the inner. Of the plovers, one of the best-known species is the Golden P. (*C. phalaropus*), also named the Yellow P. and Green P. This bird attains a length of 11 or 12 inches. It is of a greyish black above, variegated with yellow spots. The under parts are black. It visits the N. parts of Britain in summer, and migrates southwards in winter. The eggs are laid in April; they number 4, and are of a yellowish-olive colour, marked with dusky brown. The Kentish P. (*C. cantianus*) resembles another species, the *C. hiaticula*, or Ringed P. The neck is partly encircled by a black ring. The head is a rich brown above, the upper parts being ashen brown, and the under parts white. The Dotterel (*C. morinellus*) is a third familiar species, dark brown above and black below, the body being marked by various tints and by white patches. The average length is 10 inches. The Dotterel inhabits the coasts, and lays 3 eggs, resembling those of the golden P. in colour.

The name Great P. is given to the 'Thick-knee,' a bird belonging to a different genus (*Fidicnemus*) from that of the P. The Thick-knee is the *E. crepitans* of ornithologists, and is also named the Norfolk P. and Stone Curlew. Its length is about 17 inches, and the colour is a dark brown mottled with black. American species of true P. are the American Golden P. (*C. virginianus*) and the Killdeer P. (*C. vociferus*).

Plover-Crest (*Cephalophis Delalandi*), a species of Humming-bird, found in the southern parts of Brazil. The males have a very prominent head-crest. The colour is green above; the under parts are violet.

Plum (Old Eng. *plume*; Fr. *prune*; Lat. *prunum*). The original parent of the numerous and various kinds of P. is

the *Prunus domestica* of Linnæus, a native of the Caucasus and Asia Minor, 'naturalised at least in Greece, and in most temperate regions of Europe.' It has a place in British florae, but is not indigenous, nor is it frequent in anything like even a semi-wild state. In the time of Cato (born B.C. 232) the fruit was known to the Romans, though they were; it would seem, unacquainted with the tree. Pliny, however, mentions a large number of varieties. It must have been introduced early into western Europe, and many fine sorts have originated in France. In England, Gerard, at the close of the 16th c., says that he had 'threescore sorts, all strange or rare,' in his garden. Amongst those enumerated by writers of a somewhat later date are varieties still appreciated, e.g., 'magnum bonum,' the 'Orleans' (said to have been brought from France during the English possession temp. Henry V., and now corrupted into 'Arlene' by London costermongers), and the 'damask' or 'damson' (the *damascena* of botanists). It was introduced into cultivation from Damascus in Syria by the Romans. Another general favourite is the 'greengage,' which is a French variety ('Reine Claude'), brought to English notice by a gentleman named Gage during the last century. The various kinds offered by nurserymen at the present time number many hundreds. A fine P. forms a delicious dessert fruit, and it is also excellent in pies, tarts, conserves, sweetmeats, and in a dried state. A wine is made from the pulp, and a powerful spirit from the fermented pulp and kernel. Medically, plums are cooling and laxative, especially the dried fruit called 'brignoles' (see PRUNES). The wood is used in turnery, cabinet-work, and in making musical instruments, and the tree is valued in landscape-gardening from being one of the first to come into blossom. It is mostly propagated by budding. Botanically it is found impossible to draw a definite line between the wild P. and the bullace (*P. instituta*), and between the last-named and the sloe or blackthorn (*P. spinosa*), so that the three are united by our most experienced botanists into one species, the *P. communis* of Hudson. A fourth variety, cultivated in Cashmere and the Punjab, gives a very palatable fruit. Of the bullace, the fruit is extensively used for preserves, whilst the sloe is a stiff hedge-shrub, and its shoots are valued for walking-sticks, &c.; the bark has been employed as a febrifuge. The beach P. of N. America (*P. maritima*) is of service for covering coast sands, and it yields an edible but small fruit. The name P., by colonists and traders, has been applied to various fruit-bearing trees not belonging to the genus *Prunus*, e.g., Kate P. (q. v.) to species of *Diospyros*; Hog P. (q. v.) to *Spondias*; Sapodilla P. to *Achras Sapota*, and allied species; Queensland P. to *Ocotea venosa*.

Plum, Date. See DATE-PLUM.

Plumage of Birds. See BIRDS and FEATHERS.

Plumatella, a freshwater genus of *Polyzoa* (q. v.), of which *P. repens* is a familiar species, found under stones, and attached to the leaves of aquatic plants. It presents the appearance of a branched organism, the *polypites* or individual animals extending their beautiful crowns or tentacles from the ends of the branches.

Plumbaginaceæ is a natural order of dicotyledons, consisting of about 200 species of herbs (often maritime), or rarely shrubs. The bulk are natives of N. temperate regions. Some are powerfully astringent, and many are acid and blistering. Of the type genus *Plumbago*, beggars use *P. Europea* to raise blisters on their bodies to excite pity, and the root of *P. scandens* of St. Domingo (called 'Herbe du Diable') is a most energetic caustic when fresh; so also is that of the species often seen in cultivation for decorative purposes called *P. rosea*. The genus *Statice* furnishes a number of ornamental greenhouse plants, natives of the Cape of Good Hope and Canary Islands.

Plumbago. See BLACK LEAD.

Plume Bird (*Epimachus*), a genus of Insectorial birds belonging to the *Tinistrostris* group of the order, and to the family *Upipidae* or *Upipocæ*. It forms a sub-family (*Epimachinae*), in which the bill is slender and arched, and the wings of moderate size and rounded. The hinder toe is very long, as is also the tail. The tarsi are scaled in front, and the sides of the body are covered with expanded feathers. The P. B. is an inhabitant of Australia and New Guinea, where it represents the Humming Bird. The Superb P. B. (*E. magnus*) has a small body; the plumage, however, being developed to such an extraordinary extent that the body appears to measure about 4 feet in

length. The head, neck, and under parts are green, the back and wings being of a lustrous violet tint. The Twelve-thread P. B. (*E. albus*) somewhat resembles the 'Bird of Paradise' in appearance, and derives its name from the silken plumes of the back, which give off long thread-like prolongations. The plumage is for the most part of a rich violet hue.

Plume Moth, the name given to various species of Moth (q. v.) from the wings being divided longitudinally into a number of feather-like segments. The White P. M. (*Pterophorus pentadactylus*) is a familiar species, and is to be seen flying abroad at twilight. The Twenty P. M. (*Alucita hexadactyla*) is smaller than the preceding species, and has the wings divided to a greater extent. The colour is ashen grey.

Plumm'et (from Lat. *plumbum*, 'lead'), the name given to a string, fixed at its one end and with a mass of lead suspended at the other, by means of which the direction of the earth's attraction is determined. By observing its deflection from true perpendicularity when set up in the vicinity of a mountain of known mass, the earth's mass can be estimated.

Plumptre, Rev. Edward Hayes, born August 6, 1821, obtained a scholarship at University College, Oxford, and was elected fellow of Brasenose (1844). He became chaplain at King's College, London (1847), Professor of Pastoral Theology in that institute (1853), Prebendary of St. Paul's (1863), and Professor of New Testament Exegesis (1864). In 1869 he was presented to the rectory of Pluckley, and in 1873 to the vicarage of Bickley, both in Kent. Professor P. has published *Sermons at King's College* (1859); *Lazarus and other Poems* (1864); *Christ and Christendom: the Boyle Lectures for 1866* (1867); translations of Sophocles (1866) and Æschylus (1870); *Ritual Studies* (1870); *Popular Exposition of the Epistles to the Seven Churches of Asia* (1877), &c.

Plumularia, a genus of Zoophytes or *Hydrozoa* (q. v.) belonging to the *Sertulariæ* or Sea-Fin order. This genus was constituted by Lamarck, and includes zoophytes in which the stem and branches are usually branched and feathery; the cells containing the *polypites* being small, and placed on the inner aspects of the branches. The egg-vesicles or reproductive bodies appear to be scattered irregularly over the branches. Of this genus, *P. folcata*, *P. cristata*, *P. pinnata*, and *P. cetacea* are familiar British species.

Plum'ule. See SEED.

Plurality is the case of a clergyman holding more than one benefice with cure of souls. In the primitive Church both bishops and the inferior clergy were forbidden to have two churches, as was deduced by St. Ambrose from 1 Tim. iii. 2, 12. As regards bishops, 'wherever there were two dioceses before, it was not lawful for one bishop to usurp them both, except where the wisdom of the church and state thought it most convenient to join them into one.' As to the inferior clergy, when there was a scarcity of ministers, a presbyter or deacon might sometimes be required to officiate in more than one church in the same diocese, but the canons of various councils are very explicit in prohibiting any one from having his name in the church roll or catalogue of two cities in different dioceses at the same time, or in any case from drawing the revenues of both. These were paid into the common stock of the city or cathedral church from which he received his monthly or yearly portion. A canon of the Council of Chalcedon (451) on this subject was renewed by the second Council of Nice (786) and other later councils. But as the clergy themselves had the making of the laws on the subject, various relaxations of this severe law of the primitive Church were introduced, at the same time that enactments were passed against the abuses of P.; e.g., in the decretals of various popes, in the third Council (1139) and fourth Council (1170) of the Lateran, and especially the Council of Trent (1546). Certain benefices were defined in the canon law to be 'incompatible,' namely, if both required residence, or their duties to be discharged at the same time, or if one of them afforded a sufficient maintenance for the incumbent. Except these, all benefices were 'compatible,' and more than one might be held by one person at the same time. In the Church of England P. used to be a great abuse, in consequence of which many parishes were deprived of a resident incumbent. According to the latest legislation two benefices cannot be held by one person unless the two churches

are within three miles of each other, or if the populations exceed 3000 in the one and 500 in the other. In the Scotch Presbyterian Churches the only case of P. allowed is that of a minister also holding a theological chair. There is at present (1878) a committee of the Established Church labouring to secure the better endowment of the chairs, with the object of abolishing P. in every case.

Plush (Fr. *peluche*, from Lat. *pilus*, 'hair') differs only from velvet by being made of heavier and coarser materials, and having its 'pile' or hairy surface uncropped. Formerly made of worsted yarn, it was used for the liveries of male servants, and as a Sunday dress material by rural labourers. P. of silk with a cotton backing is in considerable use for upholstery purposes.

Plu'tarch (*Ploutarchos*), biographer and moralist, was born at Chæroneia in Bœotia. The facts of his life known to us are mainly gleaned from his own writings. The exact date of his birth is not known; but from the fact that he was studying philosophy under Ammonius at Delphi when Nero visited that town in A.D. 66, we may assume that he was then a young man. P. mentions his great-grandfather Nicarchus and his grandfather Lamprias; but his father's name does not occur in his extant works. P. must have visited several parts of Italy. He specially mentions Ravenna, where he saw the statue or bust of Marius; and Rome, where he spent some time. While in Italy he was employed in some public business or in lecturing on philosophy. So much was he engrossed with these duties that he failed to learn the Latin language at that time, and had to postpone his studies in that direction till late in life. He was lecturing in Rome in the reign of Domitian. According to Suidas he was Trajan's preceptor, but this is very doubtful. He returned to Chæroneia, and there discharged several magisterial offices, as well as the duties of priest of Apollo. By his wife Timoxena P. had four sons, and a daughter who bore her mother's name. He was alive in 106 A.D., but when he died is not known. P. has become immortal by his *Parallel Lives*. These, forty-six in number, are arranged in pairs, each pair containing the life of one Greek and one Roman, followed in most cases by a comparison of the two. Each pair and a parallel form a book. The following are the forty-six lives:—1, Theseus and Romulus; 2, Lycurgus and Numa; 3, Solon and Valerius Publicola; 4, Themistocles and Camillus; 5, Pericles and Q. Fabius Maximus; 6, Alcibiades and Coriellanus; 7, Timoleon and Æmilius Paulus; 8, Pelopidas and Marcellus; 9, Aristides and Cato the Elder; 10, Philopœmen and Flaminius; 11, Pyrrhus and Marius; 12, Lysander and Sulla; 13, Cimon and Lucullus; 14, Nicias and Crassus; 15, Eumenes and Sertorius; 16, Agesilaus and Pompeius; 17, Alexander and Caesar; 18, Phocion and Cato the Younger; 19, Agis and Cleomenes, and Tib. and C. Gracchus; 20, Demosthenes and Cicero; 21, Demetrius Poliorcetes and Marcus Antonius; 22, Dion and Marcus Junius Brutus. The lives of Antæxex Mnemon, Aratus, Galba, and Otho also occur in the editions after the forty-six lives. The following *Lives* by P. are lost:—Epaminondas, Scipio, Augustus, Tiberius, Caligula, Claudius, Nero, Vitellius, Hesiod, Pindar, Ciales the Cynic, Daiphantus, Aristomenes, and the poet Aratus.

As a biographer P. has certainly no equal in ancient, and few, if any, in modern times. There must, indeed, be great merits in a work that has entertained and instructed so many generations; that has been translated into so many tongues; that won the golden opinion of Montaigne and Rousseau; and that still has a charm for all degrees of men. The secret of P.'s success lies in the perfection of his portraiture. Human character is ever much the same. The *Lives* are a mirror in which any one may recognise his own lineaments.

P.'s other writings, entitled *Moralia* or *Ethical Works*, are sixty in number. They embrace a great variety of subjects, and are probably not all by him. Some of P.'s moral writings are far less studied than they deserve to be; some of the essays bearing his name, again, hardly repay perusal. The first edition of all the works of P. is that of H. Stephens (13 vols. 8vo, Geneva, 1572); the best editions those of Kiese (Leips. 1774-1782) and of J. C. Huten (Tubingen, 1791-1805). The best modern edition of the *Lives* is that by Immanuel Bekker, published by Tauchnitz (Leips. 1855-1857). The best edition of the *Moralia* is Wytttenbach's (Oxon. 1795-1800). The English version known as Dryden's, re-edited by Clough, is considered the best; that by John and William Langhorne is best known.

Plu'to (Gr. *Ploutōn*, 'the wealth-giver'), originally Hades (q. v.), is in mythology the third son of Kronos and Rhea, and brother of Zeus and Poseidon. When the world was divided among the three brothers, he obtained the realm of darkness. He sits with his head veiled, and holds in his hand a sceptre of two prongs (that of Poseidon having three). His chariot is of ebony, his horses are four, his reins are of gold. His helmet has the power of rendering its wearer invisible; and for this reason it has often been borrowed from P. The servants of P. are the Furies and Charon. In judging the dead he is assisted by Æacus, Minos, and Rhadamanthus. The cypress, box, narcissus, and adiantum were sacred to P.; oxen and goats were sacrificed to him at night. Being childless, he mounted his chariot to visit the world, and, arriving at Sicily, he became enamoured of Proserpine, who was gathering flowers in the valley of Enna. He forced her into his chariot, made a way through the bed of a neighbouring river to the lower regions, and there installed her as queen. Homer describes the realms of Hades as being only a short distance below the surface of the earth, and the abode of spirits good and bad alike. It was later that the region was divided into Elysium and Tartarus, and that the king of the lower regions received the name P. as god of the wealth taken from the bowels of the earth.

Plutonic Rocks are those rocks, such as granite and certain porphyries, which though igneous are not strictly volcanic. They are ordinarily much more crystalline than volcanic rocks, and seem to have been subjected to intense heat, but under enormous pressure. It is questionable, then, whether they have ever been molten, as volcanic rocks undoubtedly have been.

Plym'outh, the great south-western port of England, in Devonshire, and on the N. side of P. Sound, 42 miles S.W. of Exeter, and 246 W.S.W. of London by the Great Western Railway. What is commonly known as P. is in reality three distinct towns, under separate local governments, and called by the inhabitants the 'Three Towns.' P. proper lies at the entrance of the Cattewater (the estuary of the Plym), into the great P. roadstead, while stretching westward the adjoining communities of Stonehouse (q. v.) and Devonport (q. v.) lie along the mouth of the Hamoaze, the estuary of the Tamar. The Cattewater in the E. is devoted to commercial purposes, and the Tamar in the W. is appropriated to the requirements of the Royal Navy. Several of the streets of P. and Stonehouse are continuous, and the suburbs of P. and Devonport intermix. From the precipitous Hoe, a hill 100 feet high, on the seaward side of the town, with houses climbing up its landward side, a magnificent prospect is obtained of P. and its surroundings. Confining the broad Sound on the S. is the breakwater, while on the extreme verge of the horizon rises the Eddystone Lighthouse (q. v.). On the E. are the fortifications of Bovisand, Staddon Heights, Mount Batten, with its martello tower, the shipping in Cattewater, and the woods of Saltram; on the N. the town itself, reaching into the wooded upland, far inland succeeded by the wild hills of Dartmoor; on the W. Devonport, with the Cornish hills for background, and the far side of the Hamoaze, beautified by the verdant slopes and tree-clad ridges of Mount Edgcombe. The Hoe is the great lounge of P., where the regimental bands play, and at this point it was arranged (March 1878) to construct a promenade pier. The town has increased with unusual rapidity, and George Street and Bedford Street, the principal thoroughfares, are lined with fine buildings. In the quarter lying around Sutton Pool there are still quaint decayed houses with projecting fronts, peaked gables, and corbels rich in curious carving. The mother church of P., St. Andrew's, is a fine specimen of the characteristic Devonshire church architecture of the Perpendicular period, to which date it mainly belongs. Built of 'moorstone' (granite and limestone), it has three long, low aisles of equal breadth, a waggon roof, a noble, massive tower (of 1460), fine E. and W. windows, and many ancient monuments. In 1874-75 it was 'restored' by the late Sir G. G. Scott. Other churches are Charles Church, Christ Church, and Trinity, the Roman Catholic cathedral (founded 1856), a fine Early English structure, with a tower 205 feet high; those of All-Saints (unfinished, 1878), and St. Jude, and several modern Dissenting chapels. The number of small religious bodies is exceptionally large, comprising Universalists, Bible Christians, Moravians, Christadelphians, P. Brethren, Calvinists, &c. The chief secular building is the Guildhall, an Early English structure built 1870-74, and forming, with the

adjoining St. Andrew's Church, a singularly picturesque and harmonious group. It consists of two separate blocks, and contains the Great Hall (145 feet by 85, with a height of 70 feet), and the Police and Law Courts, dominated by the Great Tower, 190 feet high. Other remarkable buildings are the Royal Hotel and Theatre, an Ionic edifice; the Duke of Cornwall Hotel, in modern Gothic style, at the Millbay railway station; the P. Institution (literary and scientific), extended by the addition of a museum in 1829. The Citadel, at the E. end of the Hoe, begun in 1665, consists of five regular and two intermediate bastions. Its inner gate is an elaborate structure, and bears date 1670. Drake's Island, a famous state prison in the reign of Charles II., is now a strong fort, crowned by battery and honeycombed by casemate. The Cottonian Library, founded in 1810 by W. Cotton, F.S.A., contains 20,000 vols., and a magnificent collection of prints, 5000 original sketches (by Da Vinci, Claude, Rembrandt, Rubens, &c.), bronzes, and illuminated MSS. P. has a grammar-school, founded in the reign of Henry VII.; a public free school, next to the Jews' school in Spitalfields the largest in the kingdom, educating 1500 children; a girls' high school, founded in 1874, and a high school for boys in 1877; and the Western Independent College, affiliated to London University. The ancient harbour of P. is Sutton Pool, a sheet of tidal water 13 acres in area, connected with the Great Western and South-Western Railways, and entered by a fine channel between two piers. It is lined on the E. by shipbuilding yards and factories. The Great Western Docks, in the spacious inlet of Millbay, about a mile W. of Sutton Pool, have a deep-water approach that admits very large merchant vessels. They comprise a floating basin of 13 acres, a large graving-dock, &c., and are approached by a branch of the Great Western Railway. The famous Breakwater (q. v.), a mile long, was remodelled in 1824-41 at a cost of £1,500,000. P., which now rivals Southampton as a station for the mail steamers, is the only port for the departure of Government emigrants, and the headquarters of the Royal Western Yacht Club of England. In 1876 the port was entered by 3701 vessels of 665,637 tons, and cleared by 1913 of 392,191 tons, while the imports amounted to £1,433,307, and the exports to £117,430. P. is one of the chief ports in the kingdom for the import of cattle, and also largely imports sugar, saltpetre, hemp, hides, timber, grain, and wine. The industrial products, widely exported, are principally chemicals, soaps, artificial manure, starch, black-lead, refined sugar, gin, biscuits, candles, cement, and the beautiful native marbles. There are considerable shipbuilding yards, foundries, engineering works, tar distilleries, and stained-glass works; while the district abounds in serge factories, paper and shoddy mills, granite quarries, and clay works. P. was formerly famous for its pilchard fishery, and the fisheries for hake, mackerel, turbot, John Dorys, whiting, &c., employ (1876) 531 boats and 1241 men. The manufacture of 'P. china' was only carried on from about 1765 to 1774, and the product was the first true or hard porcelain made in the kingdom. It is now highly valued, and is richly decorated with figures, shell groupings, and corals. Up to 1875, as much as £1,486,496 had been expended on the fortifications, which are stronger than those of any other English town except Portsmouth. The great Government works are on the Hamoaze. The Royal William Victualling Yard, an imposing pile of granite buildings at Stonehouse, covers 15 acres, and cost over £1,500,000. The Keyham Steam Yard, which has a large engineering establishment and two basins capable of taking in the largest vessels, is connected by a tunnel over half a mile long with Devonport Dock and the Gun Wharf, the depot of all the Ordnance stores. The powder-works and magazines are at Kintisbury and Bull Point, close by Brunel's great work, the Royal Albert Bridge. The marine barracks are at Stonehouse, the military barracks at P. and Devonport. P. sends two members to Parliament, and Devonport, with Stonehouse, the same number. Pop. (1871) 70,091. In Old English times there was, on or near the site of P., a place called Tamarweorth. The position of the great Ridge Road, and the discovery of coins, indicate the vicinity of the Roman station *Tamara*. In *Domesday*, P. is called Sutton ('south town'); and its present name, merely an abbreviation of 'Sutton-super-P.', was not given till the reign of Henry VI. In the reign of Henry II., says Leland, the town was 'a mene thing as an inhabitation for fishcars.' In 1287 the expedition to Guienne, 325 ships, assembled in its waters. The port of departure of the various expe-

ditions led by the Black Prince, it was frequently attacked by the French; notably in 1403, when the Sieur du Chastel, of Brittany, landed in Sutton Pool and burned 600 houses. In Elizabeth's time most of the great naval adventurers sailed from P., among them Hawkins, Grenville, Gilbert, Frobisher, Davies, Raleigh, and Drake. From P. issued the fleet of 80 vessels which scattered the Armada. In 1620 the *Mayflower* sailed hence with the 'Pilgrim Fathers.' During the civil war, the town, a great stronghold of the Parliament, was subjected for four years (1642-46) to a succession of sieges and blockades. In August 1779, the combined fleets of Spain and France (88 ships) were off the Sound for four days. Napoleon, before his removal to St. Helena, was brought hither in 1815. P. was visited by Garibaldi in 1864, and by Napoleon III. in 1871. The British Association paid its second visit to P. in 1877. See R. N. Worth's *History of P. from the Earliest Period to the Present Time* (Plym. 1871), Llewellynn Jewitt's *History of P., illustrated with Wood Engravings* (Lond. and Plym. 1873), and Rowe's *Ecclesiastical History of Old P.* (Privately printed, 1876).

Plymouth, a town of Massachusetts, U.S., on Massachusetts Bay, 37 miles S.E. of Boston by rail. It has a public library, 12 churches, 2 newspapers, and manufactures rivets, nails, stoves, steel hammers, cordage, and cotton cloth. There is also a fleet of vessels engaged in the Newfoundland fisheries. Here the 'Pilgrim Fathers' disembarked from the *Mayflower*, December 11, 1620, and founded the first settlement in New England. The rock is still pointed out on which they landed, and in Pilgrim Hall there is an interesting museum of relics in connection with the early settlers. Pop. (1870) 6238.

Plymouth Brethren are a Christian sect which originated about 1830. The principal founder was a clergyman of the Irish Church named Darby (from whom they sometimes get the name of Darbyites), who left that Church and established in Dublin a sect of separatists, holding an ultra-evangelical Calvinistic theology, and calling themselves 'Brethren.' Darby afterwards came to England and made Plymouth his headquarters, from which the sect generally get the name of P. B. The chief of their peculiar tenets are as follows, although there are sects among them differing by many hair-splitting distinctions of doctrine:—(1.) They hold that the Church is the one Body of Christ, in which there can be no sects and none but living members, that is true believers in the Lord Jesus, who must all be baptized by immersion when they make a profession of belief, whether baptized before or not. (2.) They hold that every believer is a *priest*, although not a minister—priesthood being that which goes from man to God; ministry, that which comes from God to man. Of the three kinds of ministers now in the Church—Evangelists, Pastors, Teachers (*cf.* Eph. iv. 11)—the work of the two last is to guide and instruct believers inside the Church; that of evangelists, to convert sinners. And they consider it absurd for the three offices to be conjoined in one man (since one man can only be expected to have the gift for one of them), much more so that he should be chosen for his office either by patron or people. (3.) Their doctrine regarding the Law professes to be that of St. Paul (Rom. vii.), that all believers are dead to the Law, not because it is abrogated, but because its obligations are swallowed up in the power of love by union with Christ. They are often charged with antinomianism on this point, and many ignorant persons among them do understand the Apostle's language to mean that it is impossible for a believer to sin. (4.) The Lord's Day they deny to be the same institution as the Sabbath, but merely a day specially set apart, not as a command, but as a privilege, for the worship of the Lord, to which the believer is to strive to bring up the standard of every day. Every Sunday they hold a love-feast of bread and wine, which, however, is in no way regarded as a sacrament. (5.) The sanctification of a believer the P. B. hold to be completely accomplished along with his justification the moment he believes, although there may be progress in experience, knowledge, spiritual ability, &c. (6.) They repudiate the confession of sin, publicly in the congregation, as too formal and unreal, being a thing that believers can only do each for himself. (7.) One more very distinctive doctrine of the P. B. is that of the personal return of the Lord Jesus. That return will be soon, and then the saved living ones will be taken away with the raised 'dead in Christ,' to reign with Christ in the New Jerusalem for 1000 years, during which period Antichrist will be revealed, and judgments poured

out on the world. At the end of the 1000 years the rest of the dead will be raised to judgment, and then will follow the eternal state. See Darby's *Christian Ministry* (Lond. 1835); Brown's *Bible Subjects for the Household of Faith*; and Guinness's *Who are the P. B.?* (Philad. 1861).

Pneumatic Despatch, a method of sending parcels and goods from one place to another by means of compressed or of rarefied air. It is identical in principle with the Atmospheric Railway (q. v.).

Pneumatics (from Gr. *pneuma*, 'wind,' 'breath,' 'spirit'), the science that treats of the properties of gases. It is therefore a part of Hydrodynamics (q. v.) which treats of fluids generally.

Pneumatic Trough, an apparatus invented by Priestley, by means of which the collection of gases is much facilitated. It is simply a vessel of water provided with a ledge or shelf 2 or 3 inches below the surface. The glass beaker, in which it is supposed that the gas is to be collected, is set mouth downwards on the ledge, projecting, however, sufficiently over the edge to permit of the bubbles of gas formed below to ascend into it and displace the water with which it was first filled.

Pneumogastric Nerve, Nervous Vagus, or Par Vagus, is one of the three divisions of the eighth pair of cranial nerves, or that given off from the brain. This nerve and its branches are distributed more widely than the other cranial nerves. It supplies the organ of voice or larynx, the lungs, pharynx, stomach, and heart. The larynx and lungs derive from it both *motor* and *sensory* filaments (see NERVE); the stomach, pharynx, gullet, and heart, obtaining only motor fibres. It arises below the *glossopharyngeal* nerve, and its filaments are capable of being traced through the *medulla oblongata* to a nucleus or mass of grey matter lying on the lower part of the floor of the fourth ventricle of the brain. It passes from the skull through the *jugal foramen*, at which point it bears a *ganglion* or *nerve-mass*. Its course lies down the neck inside the sheath of the *carotid* blood-vessels; its distribution on the right side varying from that on the left. The nerve of the right side ultimately passes along the hinder aspect of the gullet, and entering the abdomen is distributed to the under surface of the stomach. The fibres of the left side distribute branches to the anterior surface of the latter organ. The following are the branches of the P. N. as given in Gray's *Anatomy*:—

In the jugular fossa,	Auricular.
	Pharyngeal.
In the neck,	Superior laryngeal.
	Recurrent laryngeal.
	Cervical cardiac.
	Thoracic cardiac.
In the thorax,	Anterior pulmonary.
	Posterior pulmonary.
	Esophageal.
In the abdomen,	Gastric.

The *functions* of the P. N. are intimately connected with the maintenance of the process of respiration, with deglutition or swallowing, with the action of the heart, and with other functions. Irritation of this nerve diminishes the frequency of the heart's pulsations; it may cause them to cease altogether by preventing contraction. The P. N. is in close relationship with the *sympathetic nerves*.

Pneumonia (from *pneumones*, 'the organs of breathing'), or inflammation of the substance of the lungs, is a disease of the respiratory organs of frequent occurrence. There are several varieties of P., and the distinctions depend upon the different portions of the lung, or the different constituents of any one portion, which may be inflamed, and upon the character of the accompanying fever. *Lobular P.* is the term used to express inflammation of a whole lobe more or less, or of a whole lung, or of distinct lobules or parts of lobules, with sound lung intervening. In *double P.* both lungs are involved; and when the inflammation is confined chiefly or exclusively to the air cells, it is called *vesicular P.*; and when the cellular tissue intervening between the different air vesicles, or between the lobules, is the tissue involved, it is termed *intervesicular* or *interlobular P.* When large portions of the pleura are, in addition, affected, it is called *Pleuro-P.* In P., however, the whole of the pulmonary parenchyma, including the air cells, the smaller bronchial tubes, the intervening cellular tissue, and the vascular ramifications, are generally affected.

In acute *common* or *lobular P.*, there are three well-marked

stages; viz. (1) that of congestion; (2) that of fully developed inflammation; and (3) that of suppuration. The clinical symptoms and pathological appearances of P. may be stated as follows:—The patient is said to catch a cold which settles on his chest; but it differs from an ordinary catarrh in that there is feverishness, preceded by shivering, derangement of the stomach and liver, occasionally jaundice and severe headache. The breathing is accelerated, and there is a hard, painful cough, the pain being referred, as a rule, to that particular part of the lung which is affected. After a short time the cough becomes softer, and a tough, tenacious sputum is expectorated, which adheres to the sides of the vessel. This sputum is of a reddish colour, and is generally termed the *rusty* sputum of P., the colour thereof being characteristic of the disease. The febrile symptoms are usually intense, and the temperature may rise to 105°. The pulse is at first frequent and hard, a herpetic eruption frequently appears on the lips and nostrils, and there may be great debility, dry brown tongue, delirium, and other typhoid symptoms.

In the first stage of P., viz., that of congestion, the lung or a portion of it is gorged with blood, and a quantity of red, frothy serum escapes on section. In the second stage the congestion passes into solidification; the part affected no longer crepitates on pressure, and when pressed between the finger and thumb it breaks down. In appearance the part affected resembles liver, and hence it has been termed *red hepatisation*. In the third stage, resolution or suppuration may take place. When resolution takes place, the lung is returning to its primary condition; but when the disease is advancing the pulmonary tissue remains dense, solid, and impervious to air, and its section, in place of being red, is of a reddish-yellow, or straw, or drab colour, or of a greyish tint, and a great quantity of a reddish or greyish fluid oozes from it. To this condition of the lung Lænnec applied the term *grey hepatisation*, or *purulent infiltration*, but it is in reality the stage of *diffuse suppuration*. The change from the first to the second stage may take place in twenty-four hours or less; but the change from the second to the third stage is of longer duration, and depends upon the intensity of the inflammation. In the third stage, or that of suppuration, moist sounds may be detected, owing to the admission of air into the lungs, and crepitations are heard both during inspiration and expiration; and as convalescence progresses, the *crepitatio raux* is replaced by the healthy vesicular murmur. In P. the right lung is more frequently implicated than the left, the site of the inflammation being at the base. Of 210 cases collected by Andral, 121 were on the right lung alone, and 58 on the left alone; while in 25 it was double, and in 6 the seat was uncertain. Of 88 cases observed by the same author, P. was found to affect the lower lobe 47 times, the upper lobe 30, and the whole lung at once 11.

The treatment of P. has changed very much during recent years, and bleeding, formerly so frequently practised, has been now practically abandoned. Leeching, however, may be useful in certain cases, more especially if the patient be young and plethoric. Antimonial wine, in half-drachm doses, may be given every two hours, and in the course of twenty-four hours the pulse will be diminished in volume, the temperature decreased, and free perspiration induced. For two or three subsequent days the same dose may be given every four hours. If stimulants be deemed necessary, carbonate of ammonia may be given, and also quinine in full doses as an antipyretic. For the same purpose salicylate of soda may also be administered. In Germany many physicians recommend cold bathing, or cold applications to the chest, but in Great Britain local applications of hot linseed-meal poultices are recommended. Beef-tea should be given frequently, and the temperature of the room should be kept uniformly at 60° F. During the period of convalescence the patient should be carefully tended, and even after recovery the body should be carefully protected against sudden changes of temperature, as the affected lung is always more or less permanently weakened, and the tendency to tubercular consumption is increased.

Pneumothorax (Gr. *pneuma*, 'wind,' and *thōrax*, 'the breast'), or air within the cavity of the pleura, may be caused by fractured ribs, or blows; but, in the great majority of cases, air is admitted by the bursting of a small cavity into the pleura in the progress of phthisis. The symptoms of P. are sudden and severe pain, faintness and dyspnoea, followed by swelling and lividity of the face and lips. The percussion sound

on the affected side is abnormally clear or dull, the intercostal spaces are bulged out, and the respiration sounds are absent, or are greatly diminished. In general, there is, in addition, an influx of fluid, which may be detected at the base of the pleura by dullness on percussion, and by a splashing sound when the patient is shaken.

Po (Lat. *Padus* and *Eridanus*), the largest river of Italy, rises on the E. side of Monte Viso in the Cottian Alps, near the French frontier, at a height of 6260 feet above the sea. It flows N.E. until it is joined by the Dora Baltea near Chivasso, then E. to its mouth in the Adriatic, about 20 miles from which it begins to form its delta, the chief branches of which are the P. della Maestra, 3740 feet wide; the P. di Coro, 755 feet wide; and the P. della Enocca, 525 feet wide. In the first 20 miles of its course it descends 5300 feet; and at Vellezza, after 120 miles, it is 600 feet above the sea. It is banked with dikes from Cremona to the marshes at its mouth, as it is subject to great and sudden inundations. The P. receives on the left the Dora Riparia, Dora Baltea, Sesia, Ticino, Olona, Lambro, Adda, Oglio, and Mincio; and on the right the Tanaro, Stura, Bormida, Trebbia, Taro, Parma, Enza, Erosolo, Secchia, Panaro, and Sauterno. At Turin it is 754 feet broad, at Pavia 1066, at Cremona 2657. Its length by its channel is 360 miles, but in a straight line from its source to its mouth 260 miles. It is navigable to Valenza 240 miles for vessels of 130 tons. The drainage area of the P. is 2700 sq. miles. The mean discharge into the Adriatic is 60,745 cubic feet per second. Its waters are lowest at the winter and summer solstices, and highest in May and October. The difference of level between ordinary low water and the highest known—that on the inundation of October 1872, at Artiglia, the *ventre* or highest point of the floods—was 28 feet. The discharge of fine silt at the mouth of the P. is computed at 55 million cubic yards per annum on an average, but the single flood of 1839-40 nearly trebled that quantity. The deposit extends the delta at the rate of 200 feet yearly.

Poa. See MEADOW GRASS.

Poaching (from Fr. *pocher* = Eng. 'poke,' and hence 'to intrude yourself into other people's property for the purpose of stealing game') was originally a popular word, but has now become a legal one, denoting the offence of killing or catching game illegally. By 1 and 2 Will. IV. c. 32, if any one be found on the land of another by day or by night without leave, in search of game, and having in his possession game 'appearing to have been recently killed,' the person having the right of killing the game, or his servant or gamekeeper, may demand the game, and if it is not immediately delivered they may *seize* it. 25 and 26 Vict. c. 114 empowers constables to search the person without a warrant, and, for the purpose of the act, extends the meaning of the word 'game' to include pheasants, partridges, woodcocks, snipes, grouse, black or moor game, and the eggs of these birds, and hares and rabbits. The act gives further extensive powers to constables and peace officers with regard to searching persons, or conveyances under circumstances which may reasonably cause suspicion of their having been engaged in poaching. See GAME LAWS; GAMEKEEPERS, LAW REGARDING; SALMON, LAW REGARDING.

Pocahontas, daughter of Powhatan, a powerful Indian chief of Virginia, was born about 1595. When quite a child she saved the life of Captain John Smith, who had been taken prisoner by her father, by interceding with the latter. But the truth of this occurrence, which is narrated in Smith's *True Relation*, is doubted. In 1609 she secretly apprised Smith of an intended attack by the Indians, and on various occasions supplied the famishing colonists with corn. In 1612 she was sold by the chief Japazaws to Captain Argall for a copper pot. Her father wished to rescue her, but in 1613 she married Thomas Rolfe, afterwards secretary and recorder-general of Virginia, and was baptized by the name of Rebecca. In 1616 she was brought to England by her husband, and presented at court. She died at Gravesend, March 1617, as she was about to leave for her native land, after giving birth to a son, from whom the Randolphs, Eldredges, Murrays, Bollins, and other illustrious Virginian families trace their descent.

Po'chard (*Fuligula*), the type of a sub-family (*Fuligulina*) of ducks. It has a bill nearly as long as the head, and its first quill is the longest. To this group belong a large number of

ducks included in the lists of British species. The P. (*F.* or *Nyroca fuligula*) is also known as the Dun-bird, or Red-headed plover. It arrives in Britain in October, and flies northwards in spring. The colour of the male is chestnut red on the head and upper part of the neck, and deep velvet at the root of the neck. The back is grey, mingled with a darker tint. The tail is grey mixed with brown. The under parts are white tinted with grey. The P. attains a length of 20 inches. Its nest is a rude structure placed on the ground at the edges of lakes, and the eggs, numbering ten or twelve, are of a dirty-white colour. It is captured by nets, and in pits guarded by nets. Allied to the P. is the *F. cristata* or tufted duck, the scaup duck (*F. morila*), and the canvas-backed duck (*F. vallisneria*) of America. The latter species is larger than the P., and has a lighter colour on its upper parts. It migrates southwards in winter to the Chesapeake River and to the neighbourhood of New Orleans. The tufted duck derives its name from two tufts on the head.

Poco (Ital. 'little'), a direction in music; *poco forte*, 'rather loud'; *poco piano*, 'rather soft'; *poco più allegro*, 'a little faster'; *a poco a poco*, 'gradually,' &c.

Pocock, Edward, D.D., born at Oxford, November 8, 1604, passed from Thame free school to Magdalen Hall, Oxford (1619), and thence to Corpus Christi, of which he became a fellow (1628). Having already studied Oriental languages, he went to the Levant in 1630 as chaplain to the English factory at Aleppo, and there perfected himself in Arabic, made great progress in Syriac and Ethiopic, and collected for Laud a vast number of Oriental MSS. Returning to Oxford (1636), he was appointed Laudian Professor of Arabic, but shortly repairing to Constantinople on a second quest after MSS., came back to find the archbishop in the Tower. P. thereupon retired to his college living of Childrey, Berkshire, but in 1647 regained his professorship through the offices of Selden, and a year later was promoted to the chair of Hebrew, with a Christ Church canonry annexed. He was ejected from the latter (1650), but reinstated at the Restoration, aided Brian Walton in his Polyglot Bible (6 vols. 1657), and died at Oxford, September 10, 1691, leaving two sons, Edward and Thomas, who were also distinguished Orientalists. P. published *Specimen Historiæ Arabum* (1649), *Porta Mosis*; or, *Six Discourses of Maimonides* (1655), *Carmen Abu Ismaelis Togræi* (1661), commentaries on Micah, Malachi, Hosea, and Joel, &c. His *Theological Works* were edited by L. Twells, with a life prefixed (2 vols. Oxf. 1740).—**Richard Pococke, D.D.**, a member of the same family as the preceding, was born in 1704 at Southampton, entered Corpus Christi College, Oxford, and graduated LL.D. (1733). He travelled on the Continent (1734–36), and in Egypt, Syria, Mesopotamia, and Asia Minor (1737–41), publishing on his return to England *A Description of the East and of some other Countries* (2 vols. Lond. 1743–45). He became preceptor of Waterford (1744), Archdeacon of Dublin (1745), and Bishop of Ossory (1756). Hence he was translated to Elphin, and lastly to Meath, where he died, September 1765.

Pod. See LEGUME.

Podagra. See GOUT.

Podargus, a genus of *Insessorial* birds belonging to the *Caprimulgidae* or Goat-Suckers (q. v.). The bill is compressed, and the upper mandible overlaps the lower. The base of the bill is covered with bristles. The wings are long and pointed. The tarsi are short and covered with broad scales. The P. is found in Australia and New Guinea. The tawny-shouldered P. (*P. numeralis*), Cuvier's P. (*P. Cuvieri*), the moth-plumed P. (*P. phalænoides*), and the plumed P. (*P. plumiferus*), are all well-known species. The plumage exhibits a preponderance of brown tints.

Podestà (Lat. *potestas*, 'power'), in Italy, the chief magistrate of a town, answering to our mayor or provost. The name was first given to the officers set over the Lombard cities by the Emperor Friedrich Barbarossa (q. v.), to fill the place of the elective consuls. After the peace of Constance (1183), the Italian republics, to curb the violence of domestic factions, almost universally established the office of P., to which their highest councils annually elected a noble citizen. He received a fixed salary, and on the expiration of his term of office was responsible for his administration to the state he had directed. In some cities, as Milan and Florence, the authority of the P. was merely judicial; in others he also held the chief military

command. The new constitution established in Florence by the Guelphic party in 1266 divided the criminal jurisdiction between the P. and the 'Captain of the People,' and during the war with Pisa at the beginning of the 16th c. the P. was superseded by a powerful bench of judges.

Podgoric'za (Slav. 'near the hill'), a fortified town of Turkey, near the S. border of Montenegro, and on the E. bank of the Ribnitsa, 35 miles N. of Scutari. On the close of the armistice between Montenegro and the Porte in March 1877, Suleiman Pasha led his army from Nicksics to P., devastating the little principality. On the appearance of the Russians in Bulgaria Suleiman withdrew, and subsequently P. capitulated to the Montenegrins. Pop. 7500.

Pod'iceps. See GREBE.

Podiebrad and Kunstat, Georg von Boczko, king of Bohemia, born 6th April 1420, was the son of Herant of Kunstat and P., a powerful noble of the Moravian house of Bernegg and Nidda, which had emigrated to Bohemia. An enthusiastic Hussite, of Utraquist (q. v.) views, he took part from 1434 in the struggles against the Taborites, and gained great influence in Bohemia during the reigns of the Emperor Albrecht II. and his son Ladislaus (q. v.). After having by a night attack upon Prag, in September 1448, overpowered the Catholic party, he was appointed administrator of the kingdom by the Emperor Friedrich III., and in 1452 was confirmed as such by the Bohemian Diet. After the death of Ladislaus in 1457 P. was chosen king, and on the 7th May of the following year he was crowned at Prag. He now used every means to improve the condition of the people and allay the rancour of religious parties, but his trimming between the two confessions was equally distasteful to the Catholic barons and to the headstrong Hussite bishop Rockicana. Unavailing were his negotiations (1459–61) with the German Electors to make him king of Rome and administrator of the Empire for Friedrich III. Pope Pius II.'s refusal to ratify the 'Compactaten' of Prag led to a bitter feud with P. The latter at first had the favour of the Emperor, whom he, through his son Victorin, had freed (1462) when held prisoner by his own brother Albrecht and the populace of Vienna. But Pope Paul II. having excommunicated P., the Catholic nobility declared against the king at Grünberg in 1465, and the Emperor became his enemy. In vain were the victories P. won over the 'Herrenbund' and the Bavarian 'Crusaders'; the Pope and the Emperor induced P.'s son-in-law, Mathias Corvinus of Hungary, to join his enemies. The latter having (1469) been proclaimed king at Olmutz and at Breslau, P. entered into a treaty with him, in which he promised him the succession in Bohemia. But the diet chose (February 1471) the Polish Prince Vladislav, and had already begun negotiations with the Pope for confirming the election when P. died, 22d March 1471. His sons Victorin and Heinrich I. were the Dukes of Münsterberg and Glatz, and his three daughters were married to Mathias of Hungary, Georg the Courageous of Saxony, and Friedrich I. of Liegnitz. See Jordan, *Das Königthum Georgs von P.* (Leips. 1861); G. Voigt, *Georg von Böhmen, der Hussitenkönig* in Sybel's *Historische Zeitschrift* (vol. xx., 1861); Dr. A. Bachmann, *Böhmen und seine Nachbarländer unter Georg von P.* 1458–1461, und des Königs Bewerbung um die Deutsche Krone (Prag. 1877).

Podium, in architecture, a low wall serving as a continuous base for a row of columns.

Podocarpus, a genus of trees belonging to the natural order *Taxaceæ*, and found in Australasia, the Indian Archipelago, Japan, Chili, and South Africa, but more especially in New Zealand. *P. totara* is a New Zealand tree, from 80 to 90 feet high, the timber of which is light, tough, and durable, suited both for shipbuilding and cabinet-making. The Maoris eat the fruit, which is succulent, and borne on a fleshy stalk (whence the name P.), and use the bark for roofing their huts. The wood of *P. cupressina*, a native of Java and the neighbouring islands, is also valuable, and takes a high polish.

Podolia ('Netherland') or **Kamenez**, a government of W. Russia, bounded W. by Galicia, N. by Volhynia, E. by Kiev, S.E. by Kherson, and separated on the S. from Bessarabia by the river Dniester. Area, 16,221 sq. miles; pop. (1871) 1,946,761. P. is a hilly plateau cut by the deep valleys of the

Dniester, the Bug, and their tributaries. The mild climate is favourable to the cultivation of the vine, melon, and mulberry, and the fertile, well-watered soil yields abundant corn. The meadows afford rich pasturage, and bees are extensively reared in the woods. Corn and cattle, especially oxen, are the chief exports. The chief industry is the manufacture of beet-sugar. Trade is mostly in the hands of Jews, of whom there are 195,000 in P. The greater part of the population are Russniaks or Little Russians (formerly serfs), the nobility are of Polish extraction, and the official class Great Russians. Besides these there are numerous Rumanians, Germans, Armenians, and gipsies. P. was incorporated with the Russian Empire in 1793 and 1795, and is divided into 12 districts, the chief town being Kamenez-Podolsky.

Podophthal'mata ('stalk-eyed'), a division of higher Crustaceans, so named in contradistinction to the *Edriophthal'mata*, or those in which the eyes are sessile or unstalked. The P. include the two orders *Stomatopoda* (q. v.) and *Decapoda* (q. v.). In both the eyes are supported on movable stalks or *peduncles*. The eyes of a crab or lobster exhibit the typical conformation of these organs in the P. A carapace is always present in this group.

Podophyllum is a genus of *Berberaceæ*. *P. peltatum*, or 'May Apple' of the United States and Canada, is a common

Podophyllum peltatum.

plant of damp shady woods, sending up from its thick creeping root-stock large, shield-like, lobed leaves, and white nodding flowers, to which succeed yellowish fruits, resembling a small lemon, containing an acid but mawkish edible pulp. The leaves possess narcotic and poisonous properties. It is from the root-stock that the resin called *podophyllin* is prepared. *P. Emodi*, the only other species, occurs between 6000 and 14,000 feet on the interior ranges of the Himalaya. It prob-

ably has the same qualities as the above.

Medicinal Properties of Podophyllin.—According to the investigations of Drs. Snow, Percy, and Anstie, P. acts upon the mucous membrane of the small intestines by being absorbed, as its application to an ulcer is followed by its specific effects. P. is supposed by some to act specially on the liver, as the administration of large doses is followed by the free discharge of bile; but this result seems to depend upon the intense duodenal irritation rather than on the direct action of the drug on the liver. P. is an active cathartic, useful in cases where brisk purging is required; and is used in place of calomel as a cholagogue. The dose of the *resin* is $\frac{1}{8}$ to $\frac{1}{2}$ of a grain, and it may be prescribed with aloes and soap.

Podosom'ata. See PANTOPODA.

Podu'ra, a typical genus of lower or *Ametabolic* insects represented by the various species of 'spring-tails.' They belong to the order *Thysanura*, in which the tip of the abdomen is provided with filaments, by the elasticity of which they are enabled to take leaps of considerable extent. The body is covered with delicate scales, which are used as test objects for the microscope, on account of the lines or striae with which they are marked. The species of P. occur amongst moss, in damp cellars, and in like situations. They have no wings, and they do not undergo a 'metamorphosis.'

Poe, Edgar Allan, was born at Baltimore, 19th February 1809. His father, David P., the fourth son of General David P., eloped at the age of eighteen with Elizabeth Arnold, a beautiful English actress, and went on the stage. After some years, however, General P., who had disowned his son, received him back to his home along with his wife. The young couple, however, did not survive long to enjoy their changed circumstances. They died within a few weeks of one another of consumption, leaving

three children, Henry, Edgar, and Rosalie. Edgar was adopted by a Mr. Allan, a wealthy and childless mill-owner. In his new home he received a great deal of petting without much true parental care, and this seems to have developed in him a waywardness to which he was naturally prone. In 1816 Mr. Allan took him to England, and placed him at the Manor-House School in Church Street, Stoke-Newington, where he remained about two years and a half. In 1821 he was recalled home, and placed at an academy in Richmond, Virginia. While at school here he made the acquaintance of Mrs. Helen Starnard, mother of one of his class-mates. This noble-hearted but unfortunate lady having gained the heart of the orphan boy with a few kind words, became the confidant of all his sorrows. When she died not long afterwards, P. could not at first realise his loss, and for months used to visit the grave of his friend nightly. It is almost impossible to over-estimate the influence which those lonely vigils amidst the weird sights and sounds of a churchyard exercised in moulding the peculiar character which his genius afterwards exhibited. He entered the University of Virginia in February 1826, when not quite seventeen. Here he greatly distinguished himself. In 1827 his enthusiasm was roused by the heroic struggles of the Greeks to achieve their independence, and he determined to go to Greece and join the ranks of the patriots. He was absent more than a year; but nothing is known of his travels. He returned to America in 1829, where he published his first volume under the title *Al Aaraaff, Tamerlane, and Other Poems*. Through the influence of Mr. Allan he now obtained admission as a cadet to the Military Academy at West Point, but was dismissed the service 'for neglect of duty.' Just before this took place (1831) he issued an enlarged collection of his poems under the title of *Poems by Edgar A. Poe*. On leaving West Point, P. resided for some time with his adopted father, and became engaged to Miss Royster. This match, however, was opposed by Mr. Allan, and a violent quarrel having taken place between him and P., the latter left the house never to return. Nothing is known of his movements until 1833, when he is found at Baltimore competing for prizes offered by the proprietor of the *Saturday Visitor* for the best prose story and the best poem. His tale, *MS. found in a Bottle*, and his poem, *The Coliseum*, gained for him both prizes. Mr. Kennedy, one of the judges, secured P. employment on the *Southern Literary Messenger*, for which he wrote some of his best tales. In 1836 he married his cousin Virginia Clemm, who was very young and of great beauty. Next year he became assistant editor of the *New York Quarterly Review*, but shortly afterwards removed to Philadelphia, where he became connected with *Graham's Magazine*. In 1839 a collection of his best stories appeared under the title *Tales of the Arabesque and Grotesque*. In 1843 he gained a \$100 prize with his tale of *The Gold-Bug*. He removed in the following year to New York, where he contributed to various periodicals. His poetical masterpiece, *The Raven*, first appeared in *Colton's American Review* for February 1845, with the signature 'Quarles.' In a few weeks it had been reprinted in almost every magazine in the United States, and its author found himself the literary lion of the season. But the illness of his wife was now distracting his thoughts, and next summer he removed with her to a cottage at Fordham, near New York, where she died in 1847. In 1849 P. revisited Richmond, and spent two or three months there in literary work. It is said he became engaged to his early love, now a widow with the name of Mrs. Shelton. On the 4th of October he left the town by train for Fordham. Before his departure he had complained of feeling ill, and left the train at Baltimore, where he was discovered some hours later lying in the street insensible from inflammation of the brain. He was conveyed to the hospital, where he expired on Sunday, 7th October 1849. In the whole annals of unfortunate genius there is no case in which wilful perversion of fact has made such havoc of an author's reputation as in that of P. It was his unique misfortune to have in his first biographer R. W. Griswold, an enemy as malignant as he was unscrupulous. Having obtained from the deceased author's relatives the charge of editing his works, Griswold prefaced his edition with a so-called *Memoir*, in which he gratified a long-standing enmity by heaping every species of vilification, often explicit, but oftener insinuated, upon its subject. For thirty years this elaborate libel upon the poet's memory has been reprinted along with his works, and has formed the basis of almost every estimate of his character made in American,

English, and Continental works of reference. The honour of giving to the world the first fair account of P.'s life is due to Mr. J. H. Ingram, in the *Memoir* prefixed to Black's edition. No doubt, even when we subtract Griswold's fictions, there is much in the weird and joyless career of P. which is mysterious. P.'s genius was altogether of an abnormal character, delighting in the wonderful, the ghastly, and the supernatural. His unapproachable skill in analysis and his varied lore enabled him to work out his tales with a realistic force and an elaborate and subtle detail which convince the reader in spite of himself that he is perusing a sober record of fact. The most remarkable of P.'s productions are *The Gold-Bug*, *Hans Pfaal*, *A Descent into the Maelström*, *Ligeia*, *The Facts in the Case of M. Valdemar*, *The Fall of the House of Usher*, *William Wilson*, and *The Murders in the Rue Morgue*. His poetry, which fills but one small volume, displays with the same preference for abnormal themes an intensity of thought and feeling, a subtlety of rhythm, and a perfection of technique that no other American poet has equalled. Some of his pieces, such as *The Raven*, *The Bells*, and *Annabel Lee*, are unique in literature. The best and only complete edition of P.'s works is that referred to above (4 vols. A. and C. Black, Edin. 1874).

Poorio, Carlo, Baron, son of a lawyer, was born at Naples, April 1803. Up to 1848 he took an active part in the Neapolitan struggle for freedom. In 1848, when the constitution was proclaimed, he became first prefect of police, and next minister of public instruction. On the re-establishment of the Bourbon tyranny, P. was arrested on a charge of being a leader in the secret society of the *Unità Italiana*. The sufferings of P., and many other Liberals imprisoned with him, were exposed in letters of Mr. Gladstone to Lord Aberdeen (1850-51). P. was sentenced to 24 years' imprisonment in chains, and suffered part of this punishment at Nisida, Ischia, and Monte-Sarchia. In 1859 he and sixty other prisoners were embarked on board an American vessel for New York. The exiles obtained possession of the vessel and ran her into Cork harbour. He soon returned to Italy, and was elected a deputy to the first Italian Parliament, and became a vice-president of that Parliament in 1861. He died at Florence, April 28, 1867.

Poet-Laureate. See LAUREATE, POET.

Po'etry (lit. 'creation,' from Gr. *poiō*, 'I make') has been defined by two of the world's greatest thinkers, Aristotle and Bacon, not in itself but by its accidents, the former laying stress on the fact that it is initiative and truthful, the latter on the fact that it is feigned or creative; the one holding that it produces the pleasure of a truth, the other that of a lie. Simonides makes P. merely 'word-painting.' Among the moderns, Johnson calls it 'metrical composition,' and that which pleases by 'exhibiting an idea more grateful to the mind than things themselves afford.' Whately calls it 'elegant and decorated language in verse,' and Masson 'creation and imagery in verse'—definitions that deal with the form to the exclusion of the essence, and take no account of such compositions as the Book of Job or Canticles. As colour is not essential to a picture, so neither is metre, alliteration, or rhyme to a poem; they are simply means employed by the poet as those best suited to produce an illusion on the imagination. A truer, because wider, definition of P. is Aytoun's, as 'the art which has for its object the creation of intellectual pleasures by means of imaginative and passionate language, and language generally, though not necessarily, formed into regular numbers.' Under their various heads will be found Epic P., with its kindred forms the ballad; pastoral and heroic verse; the Drama; the Lyric, to which belong the song, sonnet, ode, elegy, hymn, anthem, &c.; the Satire; and lastly, Didactic P. See Zimmermann's *Geschichte der Poesie aller Völker* (Stuttg. 1847); Dallas' *Poetics: an Essay on P.* (1852); Shairp's *Studies in P. and Philosophy* (1868), and *Poetic Interpretation of Nature* (1877); and Doyle's *Lectures on P.* (1869).

Pogge (*Aspidophorus*), the name given to more than one species of *Teleostean* fishes belonging to the Gurnard group. A well-known example is the *A. cataphractus*, known as the P., and also as the Lyrie, or Armed Bullhead, the Sea-potcher and Noble. Its body is invested by hard, horny, or bony scales resembling those of the ganoid type, and the head, gill-covers, &c., are armed with spines. The colour is a greyish-white varied with brown, and the average length is about 6 inches.

Poggen'dorff, Johann Christian, a celebrated German physicist, was born at Hamburg, December 29, 1796. In 1812 he was apprenticed to an apothecary in Hamburg, but, after two years' service as an assistant apothecary in Itzehoe, he resolved to devote himself to a purely scientific career, and in 1820 became a student at Berlin, where his diligence and talents secured him many friends. In 1824 Professor Gilbert of Leipsic, the editor of the *Annalen der Physik*, died. This scientific journal was bought up by J. A. Barth, and under the editorship of P. began to appear the *Annalen der Physik und Chemie*, which for more than half a century were known over the whole scientific world as P.'s *Annalen*. In 1830 he became professor in Leipsic, in 1834 was created honorary Doctor of Philosophy and Extraordinary Professor by the University of Berlin, and was elected a member of the Academy of Sciences in 1839, and was besides the recipient of various scientific and academic honours from his own and other nations. In February 1874, a jubilee feast, in commemoration of the fiftieth year of his editorship of the *Annalen*, was instituted. P. continued to be editor for three years later till his death, which took place January 24, 1877. He published numerous papers on physical and chemical subjects, and was besides the author of *Handwörterbuch der reinen und angewandten Chemie* (1836); *Lebenslinien zur Geschichte der Exakten Wissenschaften* (1853); and *Biographisch-Litterarisches Handwörterbuch zur Geschichte der Exakten Wissenschaften* (2 vols. 1863). It is not, however, as an original investigator that P. will hold a place in the history of science, but rather as the first editor of the *Annalen*, in which have been published the greatest discoveries of the last fifty years in experimental science. See *Annalen der Physik und Chemie* (Band clx. No. 4, 1877).

Pogonias, a genus of *Teleostean* fishes, including forms known as the 'Drumfishes,' from the grunting noises they are capable of emitting. The *P. chromis*, or 'Bearded Drumfish,' is a familiar species occurring off the coasts of N. America. It has two dorsal fins; its mouth has numerous filaments and tentacles; and the colour is a brownish-grey.

Poin'ding is the Scotch law of Diligence (q. v.), by which creditor seizes the property of his debtor in satisfaction of the debt. P. is either *real* or *personal*. Real P. proceeds on *debita fundi* (see DEBITUM FUNDI), and it affects the movables on the lands to which the debt attaches. Personal P. is used by creditors in ordinary personal obligations, and affects the debtor's movable goods and effects. There is a third mode of attachment, which has also been termed *poin'ding*, by which cattle found trespassing are detained until their owner makes good any injury they have done. The similar term of English law is *Distress* (q. v.).

Point, in heraldry, a charge of a Chevron (q. v.) shape, issuing from the dexter and sinister base of the Shield (q. v.), and tapering to the Fesse (q. v.) point. It occurs in the arms of Hanover, which formed a part of the royal arms of England from 1714 to 1837.

Point de Galle (Fr., commonly called only Galle, Ind. *galla*, 'a rock'), the second largest town and a thriving seaport in the extreme S. W. of Ceylon, situated on a bold promontory. It consists of two parts, namely the white-town, grouped round the citadel, and the native quarter, interspersed with gardens. The climate is healthier than that of Colombo or Trincomali, and the harbour, though small, is safe and accessible at all seasons. P. is of great commercial importance as a calling station for all steamships on their way to and from Calcutta, Rangoon, Penang, Singapore, China, and the Malay archipelago. The chief exports are coffee, cinnamon, Peruvian bark, and arak. The natives are skilled workers in gold and silver. Pop. (1871) 47,954. P. was founded by the Portuguese in 1518. It is now (1878) connected by telegraph with the other towns of the island.

Pointe-à-Pitre, the chief town of the division Grand Terre in the French island of Guadeloupe, on the Petit Cul-de-Sac, 20 miles N.E. of Basse Terre. It has an excellent harbour, and carries on an active export trade in sugar, rum, coffee, tobacco, &c. Pop. 15,000.

Pointed Architecture. See GOTHIC ARCHITECTURE.

Point'er, a variety of the Dog (q. v.), so named from its habit of 'pointing' at game; that is, when a bird is scented, the dog

suddenly stops, fixing his body and limbs, even the tail being kept rigid, and the whole attitude indicative of watchful silence. These qualities doubtless originated in the natural stealthy manner in which carnivorous animals at large approach the prey, strengthened by selection and the effects of habit. The English P. is much lighter than the Spanish breed. It has a wide and moderately large head, a broad muzzle, the lips or 'fews' not being over-pendant, and the tail tapering to a point. The colour is white, usually varied with black or liver tint.

Poisoning, Secret, is a mode of taking away life by poisons administered in such small doses, and, consequently, so slow in their operation, that the gradual sinking of the victims closely resembles the effects of disease or the gradual decay of nature. Wilful poisoning is generally secret, as the murderer wishes to conceal his crime; but the term S. P. usually refers to instances in which murder by the administration of poisons is carried out on a large scale, embracing a number of victims, and extending over a series of years. S. P. has been carried on in all ages, and there are numerous allusions to the practice by Greek and Roman writers, although much romance and mystery is intermingled with the accounts. In the myth of Hercules, the hero is said to have been killed by a poisoned robe. It was the fate of prominent public men to have numerous rivals and bitter enemies, and when such persons died suddenly their death was often ascribed to S. P. The preparation and dispensing of poisons seem to have been a special branch of study amongst those who professed a knowledge of chemistry, magic, or astrology; and many of them realised large sums of money by the sale of their preparations, or of the secret of their composition. Though chiefly practised in Italy and France, every country in Europe can furnish evidence of a familiarity with this pestilent art. Thus, for example, in the 21st year of Henry VIII.'s reign, an Act was passed declaring S. P. to be high treason, and sentencing those who were found guilty of it to be boiled to death. From the time of the Lombard invasion down to the 17th c., Italian history is full of instances of S. P., which show that poison was the favourite weapon of both the oppressor and the oppressed. The Borgias, who are generally singled out and held up to the horror and detestation of mankind on account of their numerous and systematic murders by S. P., seem to have merely practised the art on a more extensive scale than their neighbours.

Prior to 1648, S. P. became so common that the Catholic clergy found themselves bound to acquaint Pope Alexander VII. with the extent of the practice; and it was found on investigation that a secret society of young matrons met at the house of a reputed witch and fortune-teller, Hieronyma Spara by name, who supplied them with a slow poison, clear, tasteless, and limpid, and of strength sufficient to destroy life in the course of a day, week, month, or of such time as the purchaser desired. The 'wonderful elixir' compounded by La Spara had the effect of dissolving, by the sickness and death of the husbands, most of the unhappy marriages in Rome; and for a number of years it was found that young widows were extraordinarily abundant, a large number of unsuspecting victims having perished. The proceedings were, however, ultimately brought to light, and La Spara and thirteen of her companions were hanged, a large number were whipped, half naked, through the streets of Rome, and several ladies of high rank suffered fines and banishment. A similar organisation afterwards existed at Naples, headed by an old woman named Toffana, who prepared a poison similar to that of La Spara, and sold it under the name of *Acquetta*. In order to elude discovery, it was named 'Manna of St. Nicola of Bari,' the name of the renowned miraculous oil of St. Nicola. By means of this poison more than 600 persons are said to have been deprived of life; but Toffana was at length seized, tried, and strangled in 1719, and from this date S. P. gradually declined in Italy.

About the middle of the 17th c. the custom became prevalent in France, the victims being, as in Italy, the husbands; and the disclosures were first made by the clergy. Two Italians, named Exili and Glaser, who were suspected to have been the manufacturers and vendors of the poison, were imprisoned in the Bastille. Glaser died in prison, but Exili communicated his secret to a fellow-prisoner, named St. Croix, who, after his release from prison, made use of his knowledge by compounding the celebrated poison known as 'Succession Powder.' St. Croix

had many pupils, and not a few of them were men of high rank, position, and influence, so that S. P. became fashionable; the prisons teemed with suspected criminals, and the 'Chambre Ardente' was instituted for the special purpose of trying these offenders. In Paris, the trade was chiefly in the hands of two women, named Lavoisin and Lavigoreux, ostensibly midwives and fortune-tellers. Their houses were frequented by ladies of all classes, some for curiosity, but the greater number for the purchase of poison and instruction regarding the mode of administration. The two women were at last discovered, tried, and condemned, and were burned in the Place de Grève, 22d February 1680, and about 50 of their accomplices were hanged in various cities of France. Notwithstanding these executions, the practice continued to prevail for several years, owing to the high rank of many of the offenders, and more than 100 persons died at the stake or on the gallows before such crimes were suppressed in France.

Since the periods mentioned, S. P. has not prevailed to any great extent in Europe, but isolated cases have occurred. A German female, named Zwanziger, while serving as a house-keeper in various families in the territory of Bayreuth, in Bavaria, during the years 1808 and 1809, administered poison to no fewer than seventeen individuals in the course of nine months, three of whom died; and Gottfried, a woman in affluent circumstances and of good position in the town of Bremen, pursued her criminal career for fifteen years undiscovered, and when detected in 1828 had poisoned fourteen persons, and administered poison unsuccessfully to several others from the mere gratification of a malevolent temper, or the removal of supposed obstacles to her matrimonial schemes.

It is generally supposed by those unacquainted with such subjects that the actors in such dramas were acquainted with certain virulent poisons unknown to modern toxicologists, which would take effect after the lapse of a definite and often remote interval; but Sir Robert Christison remarks:—'With regard to the noted instances of S. P. which occurred towards the close of the 17th c. in Italy and France, it is plain to every modern toxicologist, from the only certain knowledge handed down to us of these events, that the actors in them owed their success rather to the ignorance of the age than to their own dexterity. And as to the refined secrets believed to have been possessed by them, it is sufficient to say, that although we are now acquainted with ten times as many and ten times as subtle poisons as were known in those days, yet none exist which are endowed with the hidden qualities once so universally dreaded.' See Sir R. Christison's *A Treatise on Poisons* (Edin. 1829; 4th ed. 1845).

Poisons. A poison is commonly defined to be a substance which, when administered in *small quantity*, is capable of acting deleteriously on the body; and, in popular language, it is applied to those substances only which destroy life in small doses; but this definition is too limited for the purposes of medical jurisprudence, for some substances have not been known to act as P. except when taken in large doses. In a medico-legal point of view, whether a man dies from the effect of a small dose of arsenic or from a large dose of nitre, the responsibility of the person who criminally administers the substance is the same, the result is the same, and the quantity required to kill cannot be made a ground for distinguishing a poisonous from a non-poisonous substance. Dr. Taylor says: 'Perhaps the most comprehensive definition which can be suggested is this: a poison is a substance which, when taken internally, is capable of destroying life without acting mechanically on the system;' but this definition does not comprehend those substances which act as P. by absorption when applied either to the skin or to an abraded surface. It is usually considered that a medicine in a large dose is a poison, and that a poison in a small dose is a medicine; but the medicinal or poisonous effects of such substances may depend not so much upon the quantity taken as upon the frequency and length of time it has been administered. According to law, the substance administered may not be a poison in the medical signification of the term, and it may not be popularly considered as such; yet, when taken, it may be destructive to life—such as powdered glass, iron-filings, sponge, pins and needles, &c.

Classification of P.—P. have been divided into three classes, according to their mode of action on the system—namely, Irritants, Narcotics, and Narcotico-Irritants. The irritants, when

taken in ordinary doses, speedily occasion violent vomiting and purging, usually accompanied with intense pain in the abdomen, the effects of the poison being chiefly manifested on the stomach and intestines, which they irritate and inflame, and hence their designation. Some irritants do not possess any corrosive action, such as arsenic, the poisonous salts of baryta, carbonate of lead, cantharides, &c., and these are often called pure irritants, as they do not exert any destructive chemical action on the tissues with which they come in contact. Many substances, however, belonging to this class of P., possess corrosive properties, such as the strong mineral acids, caustic alkalis, bromine, corrosive sublimate, &c., and the act of swallowing them is usually accompanied by an acrid and burning taste, extending from the mouth down the oesophagus to the stomach. The action of the purely irritant P. is generally more slowly manifested than that of the corrosive P., the symptoms rarely showing themselves until at least half an hour has elapsed from the time that the poison has been swallowed; while the action of corrosive P. is generally manifested immediately; as mere contact produces disorganisation of the tissue, the corrosion being due to a decided chemical action. The greater number of irritant P. belong to the mineral kingdom, though a few are derived from the animal and vegetable kingdoms, and they may be divided into the non-metallic and metallic irritants. The narcotics and the narcotico-irritants have their operation confined chiefly to the brain and spinal marrow, and their action is generally manifested by headache, giddiness, paralysis, stupor, and sometimes by convulsions. The pure narcotics neither irritate nor inflame the stomach and bowels; they are few in number, and belong to the vegetable kingdom. The narcotico-irritants are *spinal* and *cerebro-spinal* P., and have, as their name implies, a compound action. They give rise to vomiting and purging like irritants, and subsequently produce stupor, coma, paralysis, and convulsions from their action on the brain and spinal marrow. This class of P. is very numerous, embracing a large number of well-known vegetable substances.

Irritant P. are divided into four groups—the non-metallic, the metalloids, the metallic, and those of an organic nature, *i. e.*, derived from the vegetable and animal kingdoms. The non-metallic irritants comprise the *mineral acids*, as sulphuric acid or oil of vitriol, nitric acid or aquafortis, and hydrochloric acid; the *vegetable acids*, as oxalic acid, bimoxalate of potash, tartaric acid, and acetic acid or common vinegar; the *alkalies*, as potash, soda, and their carbonates, ammonia and sesquicarbonate of ammonia. The metallic irritant P. comprise arsenic, arsenious acid, sulphurets of arsenic, and other compounds, corrosive sublimate or perchloride of mercury, calomel, white and red precipitates, sulphurets of mercury, cyanide of mercury, peroxides and nitrates of mercury, lead, acetate of lead, sulphate of copper and other salts of copper, arsenite of copper or Scheele's green, tartarised antimony or tartar emetic, chloride of antimony, sulphate and chloride of zinc, carbonate of zinc, preparations of tin, silver, gold, iron, bismuth, chrome, and bichromate of potash. The vegetable irritant P. are very numerous as a class; but the more important are aloes, colocynth, gamboge, jalap, scammony, savin, croton oil, castor seeds, oil of turpentine, oil of tar, dandelion, ergot of rye, carob or locust bean, cantharides, and poisonous food, as fish, mussels, salmon, cheese, sausages, and diseased flesh of animals.

The principal narcotic or cerebral P. are opium and its compounds, as Godfrey's cordial, Dalby's carminative, paregoric elixir, Dover's powder, morphia and its salts, black drop, sedative solution, prussic acid, bitter almonds, nuxvom, cyanide of potassium, hyoscyamus niger, lactuca virosa and sativa, lettuce opium, solanum dulcamara and nigrum, camphor, alcohol, ether, chloroform, and amylene. The more important spinal and cerebro-spinal P. are nuxvomica, strychnia, colchicum, white hellebore, digitalis, conium maculatum, ananthe crocata, datura stramonium, aconite, deadly nightshade, tobacco, lobelia, cocculus indicus, laburnum, mushrooms, yew, and privet.

In all cases of poisoning the first indication is to empty the stomach, which may be done by tickling the fauces with a feather; or by the administration of copious draughts of tepid water, to which mustard may be added, or a scruple of sulphate of zinc, or some other emetic. As antidotes for the mineral acids, chalk or magnesia in water or milk should be given freely; for the alkalis and their carbonates, vinegar or lime-juice and water, and afterwards milk, should be given; for oxalic acid, chalk or magnesia in water, so as to form an insoluble oxalate of lime or

magnesia; for arsenic the hydrated peroxide of iron, and demulcent fluids such as flour and water, and milk; for corrosive sublimate, the white of egg, which forms an insoluble inert mass; for nitrate of silver, chloride of sodium or common salt, dissolved in water; for tartarised antimony, the decoction of bark or gall-nuts; for acetate of lead, sulphate of magnesia or Epsom salts, which converts it into an insoluble sulphate. In cases of poisoning from noxious gases, as carbonic acid gas, the patient should be at once removed to the free open air, after which artificial respiration should be had recourse to. Where there is heat of skin, cold water should be applied to the head and spine; but if the surface be cold, a warm bath should be employed. Both carbonic acid and carbonic oxide act as powerful narcotic P. Sulphuretted hydrogen gas appears to act as a narcotic poison when concentrated, but like a narcotic irritant when much diluted with air. Many of the gases, chiefly produced during chemical investigations, are highly poisonous, as arseniuretted hydrogen, cacodyl, &c.

In addition to the above enumerated P., there are many that affect the system by direct introduction into the circulation, through a puncture, or abrasion, or by absorption; and while some P., derived from the mineral, vegetable, and animal kingdoms, act as efficiently if introduced into the stomach, there are some P. which act only by direct introduction into the blood, and are inert when introduced into the stomach, such as P. derived from the dissection of recently dead bodies; from the bites and stings of insects, and of rabid and venomous animals. The P. of such diseases as glanders, hydrophobia, malignant pustule, and of the whole class of the zymotic diseases, may also be added to the list.

Regarding the legal definition of P., Dr. Taylor says, 'The law never regards the manner in which the substance administered acts. If it be capable of destroying life or injuring the health of an individual, it is of little consequence, so far as the responsibility of a prisoner is concerned, whether its action on the body be of a mechanical or chemical nature. If the substance criminally administered destroy life, whatever may be its nature or mode of administration, the accused is tried on a charge of murder or manslaughter, and the duty of the medical witness consists in showing that the substance taken was the certain cause of death. If, however, death be not a consequence, then the accused is tried under a particular statute for the attempt to murder by poison. Thus it is laid down that "whoever shall administer or cause to be taken by any person any poison, or other destructive thing, with intent to commit murder, shall be guilty of felony, and being convicted thereof shall suffer death." Although the administering be followed not by death but only by bodily injury dangerous to life, it is still a capital felony, provided the *intent* has been to commit murder. The *attempt* to administer to any person any poison or other destructive thing with the like intent, &c., although no bodily injury be effected, is felony, punishable by transportation for life, for fifteen years, or imprisonment for any term not exceeding three years.'

The Act 14 and 15 Vict. c. 13 requires every person who sells arsenic to enter in his books the date and quantity and purpose of its use, all which particulars may be inquired into before the sale. It is not to be sold to one who is unknown to the vendor unless in presence of a witness who is known, and whose place of abode is recorded in the book. The arsenic must also be mixed with soot or indigo, in the proportion of half an ounce of soot or indigo to a pound of arsenic. Those who offend against the Act incur a penalty of £20. According to Act 26 and 27 Vict. c. 113, extending to the United Kingdom, whoever sells or offers to sell poisoned grain, seed, or meal, incurs a penalty of £10. Whoever sows, lays, or puts on ground such poisoned grain incurs a like penalty. The use of poisoned flesh is also prohibited. See Sir R. Christison, *A Treatise on Poisons* (Edin. 1829; 4th ed. 1845).

Poitiers, capital of the ancient province of Poitou, and of the modern department of Vienne, lies on a low hill at the junction of the Boivre and the Elain, on the Bordeaux-Orleans railway. The former of these streams is here crossed by two bridges, the latter by six, two of which are for the railway. The town is widely but irregularly built, with steep, crooked streets, and is surrounded with an ancient wall, though the suburbs stretch away down into the valleys on either side. It is the seat of a bishop, and contains a university academy with three faculties

(jurisprudence, science, and literature), a public library of 30,000 vols. and MSS., a museum, a theatre, various scientific societies, and a celebrated lyceum. The University of P., founded by Charles VII. in 1431, was abolished during the Revolution. Among the large number of churches and chapels the most notable is the cathedral of St. Pierre (1152-1379), which contains the tomb of Richard Cœur de Lion. It is one of the most beautiful cathedrals in France. The church of St. Jean, which has now been converted into a museum, dates from the earliest centuries of the Christian era. The district around P. contains many remains of Celtic and Roman antiquity. The name P. is a corruption of the Latin *Pictavi*, which was derived from the Gallic tribe the *Pictavi*, who inhabited this part of the country in Cæsar's time. Here Hlodwig defeated and slew Alaric II., the West-Goth, in 507. In 1356 the battle of P. was fought between Edward the Black Prince, at the head of about 12,000 English and Gascons, and King John of France, who commanded an army 60,000 strong. The conflict took place at Maupertuis-le-Beauvois, about 5 miles N. of P., and ended in the total defeat of the French troops and capture of the king. Pop. (1872) 28,247.

Poitou, the name of a former province in the W. of France, embracing an area of 8650 sq. miles, which now includes the departments of Vienne, Deux-Sèvres, Vendée and part of Charente-Inférieure, Charente, Haute-Vienne, Indre-Loire, and Maine-Loire. Its capital was Poitiers (q. v.), and both names seem to have been derived from *Pictavi*, the name of the original Gallic inhabitants of the district. Up to the time of Pippin P. belonged to Aquitania, but was united by him to the Frankish state. Through Eleanor of P. it came into the possession of Louis VII. of France on his marriage with her, and afterwards into that of Henri of Anjou, her second husband, who became Henry II. of England. Under Henry III., however, it again reverted to France. After having again come into the possession of England for a short time by the peace of Bretigny (1360), it was afterwards reconquered by Charles V. and united to the French crown.

Poitrel is the name that was applied to the hinged or flounced plate which covered the breast of an armour-clad warrior in the 15th c.

Pola, the chief naval station of Austria, in the markgratdom of Istria, 75 miles S. of Trieste by sea. It is situated on a landlocked bay of the Adriatic, which forms a magnificent natural harbour. But still more than as a modern naval station is P. interesting historically. The history of the place begins with the Roman conquest of Istria in 178 B.C., after which it became a Roman colony and a flourishing seat of commerce. Siding with the republic in the civil war, it was destroyed by Julius Cæsar. Restored by Augustus, it again attained prosperity, and became a great war harbour, with a pop. of 35,000. In 550 A.D. Belisarius, Justinian's general, assembled an army here to chastise the neighbouring pirates. Venice took P. in 1148; in the struggles of the republic with the Genoese the town was frequently destroyed, and from the last of those disasters, in 1379, it never fairly recovered. The chief of the many interesting remains of the Roman colony is the amphitheatre, which presents an imposing appearance from the sea. It is 78 feet high, 344 in diameter, and could accommodate 15,000 persons. The lower storeys consist of two series of arches (72 in number, and 18 feet in height), one above the other. The structure dates from about 150 A.D., and the exterior alone is in good preservation. Its main peculiarity is that it lies on the slope of a hill, which supplied a natural provision to the seats at one side. The Temple of Augustus and Roma, of B.C. 19, has a colonnade of six Corinthian columns 23 feet high, with a beautiful frieze. Parts of the Roman wall still stand, and two of its gates—the *Porta Aurea* or *Aurata*, and the double *Porta Gemina*. The *duomo*, though of inferior interest to the rich earlier remains, is a fine basilica. The town is the seat of a bishop, but has no industrial importance. Pop. (1869) 16,324. See the works of Allason, Kandler, and Gareis, and Freeman's *Historical and Architectural Sketches* (1876).

Polacca, or **Polacre**, a three-masted vessel used in the Mediterranean, sometimes square-rigged, sometimes with a peculiar form of sail called P. The main and fore masts, being of one piece, have neither tops, caps, nor cross-trees.

Polacca, or **Polonaise**, a musical composition, imitative of Polish dance tunes, usually in 3 time, and *andante* or *adantissimo* in movement.

Poland, formerly a powerful independent kingdom of Central Europe, whose boundaries in the course of time underwent great change, including, at the beginning of the 11th c., about 87,600 sq. miles; in the 17th c., the period of its greatest prosperity, stretching from the Baltic to the Black Sea, and including 361,400 sq. miles, with a pop. of 20,000,000; and at the middle of the 18th c., before its first partition, having a pop. of about 13,000,000, and an area of 276,500 sq. miles, embracing the provinces of Great P. (with Kujavia, Masovia, and Polish-Prussia), Little P. (with Podlachia, Red Russia, Podolia, Volhynia, and the Polish Ukraine), and Lithuania (with Polish Livonia, Samogitia, &c.). The great plain between the Baltic, the Carpathians, and the Euxine is said by Jornandes and Procopius to have been inhabited in the 6th c. by Wendes, Slavs, and Esthlonians. While the first of these pushed westwards to the Elbe, the last were gradually crushed up to the shores of the Gulf of Finland, and the Slavonic Czechs and Moravians (about 623 A.D.) possessed themselves of Bohemia and Moravia. The country between these and the Russians was occupied by the Slavonic Lechs, of whom the chief tribe was called the *Polane* or *Poles* (from *pole*, 'a plain'), whom we find in the 8th c. forming themselves into a state on the Vistula. The history of P. properly begins with Miesko or Miecislav I., who from about 963 held his lands in fee of the Emperor Otto I., and in 967 introduced Christianity. His son, Boleslaw I., Chobry ('brave'), who ruled from 992 to 1025, was the founder of the Polish kingdom. In the year 1000 he established the independent Archbishopric of Gnesen, with the suffragan bishoprics of Salzholberg (Kolberg), Cracow, and Breslau. Boleslaw conquered Silesia, Lusatia, Moravia, Bohemia, and all the lands to the eastward as far as Kiev, and in 1024 received from the Pope the title of king. From about this period a yearly tribute of Peter's pence was paid to the Pope by all Poles save the nobles and clergy. After the death of Boleslaw's son and successor, Miecislav II. (1025-34), who lost the royal title and Lusatia, wild anarchy prevailed, and struggles between the nobles (*szlachta*) and the seifs, till his son Casimir I. (1041-58), who had retired to Germany, with the help of the Emperor Heinrich III. won back the power. Casimir's son, Boleslaw II. (1058-79), restored (1076) the kingly title, but was driven from the throne by his nobles for the murder (1079) of Bishop Stanislaus in the church at Cracow, the act which gave to P. her patron saint and martyr. The brother of Boleslaw, Wladislaw I. (1079-1102), who called himself simply 'Duke,' was succeeded by his warlike son, Boleslaw III. Krzywosty ('Wry-mouth'), who rendered tributary all the E. part of Pomerania as far as the Oder, and gained possession (1121) of the whole Pomeranian coast, for which he swore fealty (1133) to the Emperor Illothar. Boleslaw III. dying in 1138 divided the country between his four sons, and gave his eldest son Wladislaw II. (1139-46)—who received Cracow and Silesia, and became the ancestor of the Dukes of Silesia—a sort of lordship over his brothers. A fifth brother, Casimir II. (1177-94), passed over at the division, reunited all P. except Silesia under his rule, but lost Pomerania. After his death the kingdom underwent new divisions, and a fatal step was taken by his younger son Konrad, to whom had fallen Masovia, calling in the aid of the Teutonic Knights (q. v.) against the heathen Prussians. After long and bloody wars they possessed themselves of all the lands from the Oder to the Gulf of Finland, and by shutting off P. from the sea, took away her northern commerce and trade. The feeble rulers that succeeded Casimir were powerless to prevent internal anarchy and the destructive incursions of the Mongols. At length Wladislaw I. Lokietek ('the Short') (1305-33), had the fortune to reunite the kingdom by joining together Great and Little P. His son, Casimir III. the Great (1333-70), was the last of the Piast dynasty. He conquered Galicia, Volhynia, and Podolia, extended and confirmed the powers of the Diet, or assembly of the nobles, encouraged education, agriculture, and trade, and by his liberality to the lower orders earned the title of the 'Peasants' King.' From the accession (1370) of Casimir III.'s sister's son, Lewis the Great of Hungary, till his death in 1382, P. was united with that kingdom; and by the marriage of Lewis's daughter

Heating with Jagello (q. v.), in 1385, Lithuania was joined to P. Under the kings of this house—Wladislaw II. (1386–1434); his two sons, Wladislaw III. (1434–44), who was also king of Hungary, and Casimir IV. (1444–92); the three sons of the latter, John I. Albrecht (1492–1501); Alexander (1501–6); Sigismund I. (1506–48); and Sigismund's son, Sigismund II. August (1548–72)—under whose government Protestantism made considerable progress—the kingdom was extended to its old boundaries, but at the same time there was a great increase in the power and imperiousness of the nobles, through which the kings gradually lost the power to curb the republican spirit that prevailed in the nominal monarchy of P. It was the misfortune of P. to lose this wise line of princes at a time when all Europe was in a state of transition, and the ferment of innovation led to the questioning of every opinion and right. P. now became a virtual republic under the form of an elective monarchy, and so remained for 200 years till its dissolution under the eleventh elected king. The powers of the king were greatly restricted by the Diet, which consisted of the 'senators' (the highest nobles and clergy) and the other nobles, and was divided into five classes: (1) the Archbishop of Gnesen and the bishops; (2) the thirty-four 'Waiwodes,' or governors of provinces; (3) the 'Castellans,' originally commanders of fortresses; (4) the nobles; and (5) the deputies of the chief towns. In 1573 were concluded the *Pacta conventa*, by which it was provided that only after the death of a king should his successor be chosen, and then by a diet called by the primate of the kingdom, and attended by all the nobles in arms, while the *Pax dissidentium* promised complete toleration and equal rights to Christians of all creeds. In vain did Henri III. of Anjou (elected 1573) strive to reverse these changes, and after a reign of four months he secretly left P. to ascend the throne of France. After the brave Stephan Bathori (q. v.) (1575–86), there ruled in P. three kings of the Swedish house of Vasa. The election of Sigismund III. (1587–1632) was brought about by the Zamojski party in 1587, because he had been a sister's son of the last of the Jagello line, and much was expected from a union of the two most powerful crowns of northern Europe. On the death of his father Johann II. in 1592, he inherited the crown of Sweden, but the connection between Catholic P. and Protestant Sweden was soon torn asunder, the result being an intermittent war between the two countries till the peace of Oliva in 1660. The weak Sigismund at his death (1632) left P. in anarchy, threatened both by Sweden and Russia, to his able son Wladislaw IV. (1632–48), who forced (1634) the Russians at the peace of Palanowka to resign all their conquests in P., and by the treaty of Stuhmsdorf with Sweden (1635) restored the Polish supremacy over the duchy of Prussia. He was succeeded by his half-brother John II. Casimir (1648–72), under whom was introduced (1652) the *Liberum Veto* (Polish, *Nie pozwalam*, 'I cannot consent'), a fatal license, which placed all legislative power at the mercy of each individual nuncio. Worst of the Tartars, the Cossacks, the Turks, the Russians, and the Swedes, John Casimir fled from his throne, leaving Karl Gustaf of Sweden master of P. from Courland to the Carpathians. But regaining courage, and rallying his nobles, he expelled the invaders, and recovered the greater part of P. by the peace of Oliva (1660); which, however, gave to Sweden Livonia and Esthonia, and took from P. the overlordship of Prussia. After an unsuccessful war with Russia, John Casimir was forced at the peace of Andrussov (1667) to yield Smolensk, Kiev, and all the Ukraine E. of the Dnieper. On the 16th September 1668 he abdicated, and on the 16th December 1672 died at Nevers as Abbot of St. Germain des Prés. After violent disputes with the higher nobles, who wished to elect a foreign prince, the lesser nobles set the poor and incapable Michael Thomas Koribut Wisniowiecki upon the throne (1672–74); during whose reign John Sobieski led that campaign against Turkey which is known as 'the miraculous,' and while the king was dying at Lemberg from the effects of a debauch, left 40,000 Mussulmans dead on the field of Choczim. This victory won the crown for John III. Sobieski (q. v.), who for a time covered P. with glory, but was powerless to prevent the decline of the kingdom, due to the instability of its institutions. He was succeeded by two kings of the House of Saxony, August II., 1697–1733—who as Elector of Saxony was Ferdinand August II.—and August III. The former having joined the combination against Karl XII. of Sweden, P. was overrun by Karl, who placed on the throne Stanislaus Lesczinsky (1704–9). But after

the battle of Pultava August regained his powerless crown, which it had before cost him great sums to win. After his death the contentions inevitable to a Polish election deepened into a general war between the Great Powers of Europe, some in favour of the banished Stanislaus Lesczinsky, the choice of the majority of the nation, others supporting August III.—as Elector of Saxony Friedrich August II.—the son of the late king, who was recognised in 1735 at the peace of Vienna. The 'Dissidents,' who in 1563 had obtained equal rights with the Catholics, had already in 1717 lost great part of these; the Jesuits fed the flame of persecution, and from their iniquitous capital tribunal at Thorn (1724) sowed the seeds of deadly hatred. By the Diets of 1733 and 1736 the Dissidents were excluded from all public offices, and henceforth they were subjected to severe oppression. In taking their part Russia found a welcome opportunity for interference in the domestic affairs of her de-ranked and anarchical neighbour. After the death of August III. (1763), Catharine set on the throne her discarded lover Count Stanislaus August Poniatowski (1764–95). 15,000 Russians forthwith entered P. to support Stanislaus and protect the Jews and Dissidents, and the real power lay in the hands of Repnin, the Russian ambassador at Warsaw. The national party in the Diet of 1766 seeking to abolish the *liberum veto*, and sharpen the laws against the Dissidents, Russia seized the opportunity to send 40,000 men into P. When under their protection Prince Radziwil concluded the General Confederation of Radom, June 1767, and in October the Diet set about preparing a new constitution to be guaranteed by Russia. Repnin demanded the equality of the Dissidents and banished the recalcitrant bishops to Siberia. The new constitution had not yet been accepted (24th February 1768) by Russia and Prussia, when the Confederation of Bar was formed (20th February) for the protection of the Catholic Church and national freedom with Marshal Krasinski at its head. Though it succeeded in inducing the Turks to declare war against Russia (30th October 1768), that power had troops enough to occupy South and East P. at once. In the summer of 1770 Austria seized the Hungarian comitat of Zips, which in 1412 the Emperor Sigismund had pledged to P., and Friedrich of Prussia sent across his frontier a force of 12,000 men. In vain did the confederates of Bar, with the moral support of France, seek to gain possession of Warsaw, raise Lithuania in arms, and seize the weak king (3d November 1771), that they might force his abdication in favour of Pulawski. Everything miscarried. Already had the Prussian and Austrian ambassadors plotted in St. Petersburg and Vienna the first partition of P. Maria Theresa at first rejected the proposal with indignation, but was soon persuaded to put forward extensive claims. After the conclusion of a secret treaty on the 5th August 1772, Russia, Prussia, and Austria presented their claim to the Diet of Wilna. Russia took (23d August 1773) Polish Livonia, the Waiwodeships of Vitebsk and Mstislav, half of Polozk and part of Minsk,—in all 43,800 sq. miles; Prussia got Polish Prussia (except the towns of Danzig and Thorn), and a part of Great P. (the Netze District), 14,240 sq. miles; and to Austria fell Zips, half of the Waiwodeship of Cracow, and part of Sandomir, Red Russia, &c.,—about 28,000 sq. miles. The Poles now for the first time saw their mistake. Straining every nerve to secure the independence of what was left to them, and encouraged by the new king of Prussia's promise of protection, they adopted (3d May 1791) a new constitution, which won the praises of Fox and Burke and the approval of Prussia. This provided that after the death of Stanislaus P. should be a kingdom hereditary in the House of Saxony, and with institutions based on the more liberal principles of modern times, the *Liberum veto* being abolished, and the third estate admitted to national representation and public offices. But Catharine rejected it in her declaration of the 18th May, and the Turkish war ending soon after with the Peace of Jassy, she had her hands free to oppress P., while the Prussian king found it more convenient to join in a new robbery than to risk a struggle in support of his promise. Under Catharine's protection, a confederation was formed at Targowitz against the new constitution. After a brave resistance the Polish troops were forced to yield to Russia's superior strength, and in 1793 was made a second partition, by which Russia obtained a great part of Lithuania, with the Ukraine, Podolia, the E. half of Volhynia, &c. (110,700 sq. miles); and Prussia the waiwodeships of Posen, Gnesen, and Kalish, &c., with the towns of

Danzig and Thorn (28,200 sq. miles). P. was now reduced to 84,646 sq. miles, with a pop. of 3,500,000; the king had merely the name, and Russian soldiers and officials filled the land with deeds of riot and brutality. At length an attempt was even made to disarm the remnant of the Polish army, but the ill-treated folk rose (March 1794) to the resistance of despair, Kosciusko placed himself at the head of his countrymen, the Russians were driven from Warsaw, and in the sacred struggle for fatherland and freedom the valour and devotion of the Poles seemed about to atone for the faults of bygone generations. The battle of Racławicz (4th April), and the relief of Warsaw, besieged by the Prussians (5-6 September 1794), are the brightest days in the life of the Polish nation. But they came too late. Without fortresses or military skill, without allies or even arms, P. was no match for her great oppressors. Kosciusko was defeated and taken prisoner at Maciejowicz, and Suwaroff advanced on Warsaw, which, on the fall of its suburb Praga was forced to yield. Austria now demanded a share of the spoil, the three Powers proceeded to the *third and last partition* of P. (24th October 1795)—in which Russia took 44,460, Prussia 21,830, and Austria 18,250 sq. miles—and P. was torn from the number of European nations. While the destruction of P. has been fitly called 'the greatest crime of modern times,' the fate of that unhappy country will for ever stand in history as a warning to all states in which either the highest or the lowest classes wield a preponderating power, the surest token of a nation's fall. The king without a country was dismissed with a pension, and died at St. Petersburg in 1798. The promises of the three robber Powers to respect the nationality of the Poles, and to suffer certain national bodies to direct legislation, taxation, and trade, though repeated, confirmed, and extended by the Treaty of Vienna in 1815, were never kept. The declining hopes of the Poles were raised by the victories of Napoleon, who formed in 1807, in connection with the kingdom of Saxony, a duchy of Warsaw out of lands (40,415 sq. miles, with a pop. of 2,200,000) yielded by Prussia at the Treaty of Tilsit. To this West Galicia (61,320 sq. miles, with a pop. of 3,800,000) was added in 1809. But his reverses in Russia in 1813 turned the scale, and at the Vienna Congress (1815) a 'Constitutional kingdom of P.,' whose crown was united to that of Russia, and a little 'Republic of Cracow,' were erected. On the 27th November 1815 P. received a free constitution with two chambers, and the promise of a separate army and finances, with a native viceroy and responsible ministers. The first diet met in 1818, but already in 1820 the Emperor Alexander I. expressed displeasure at the rejection of certain Government bills, and on the death of the first viceroy a successor was not appointed, but the Grand Duke Constantine thenceforth ruled alone with brute violence as 'military governor.' In 1825 ceased the freedom of the press, and an arbitrary addition to the constitution suppressed the Diet. Secret societies were organised, and on the 29th of November 1830 the Poles rose in revolt. Several Russian generals were assassinated, and the Russian troops (7000) fled from P. On the 4th December a provisional government was established under Prince Czartoryski, Ostrowski, and Lelewel. Soon after General Chlopicki was chosen Dictator, but he busied himself more with negotiations with the emperor than with military preparations. Nicholas refusing to treat with 'rebels,' Chlopicki resigned. A new government under Czartoryski formally deposed (25th January 1831) the House of Romanoff, and proclaimed the reunion of Lithuania and W. Russia with P. On the 6th February General Diebitch with 130,000 Russians entered P., and on the 14th began the struggle. In the first actions the success lay with the new Polish leader Skrzynecki, but after the drawn battles of Wawer (20th February) and Grochow (25th February) the Poles were compelled to retreat to Warsaw. On the 1st April they won a great victory at Wawer, but on the 26th May they suffered a severe defeat at Ostrolenka, from which they never recovered. Warsaw capitulated on the 8th September, and by the 16th the Polish rising was at an end. Upwards of 40,000 Poles emigrated to England, France, and Switzerland. The independence of P. was annihilated by the 'Organic Statute' of the 20th February 1832, and the Polish army was incorporated with the Russian. The universities of Warsaw and Wilna were closed. Warsaw and Modlin became Russian fortresses. Numerous estates were confiscated and given to Russian officers, and their former owners consigned to the *publits* of Siberian fortresses. The country was divided into 'governments' instead of 'waiwode-

ships,' the old coinage, weights, and measures were succeeded by those of Russia, and in 1835 the customs frontier between Russia and P. was blotted out. An intended revolt in 1843 under Mickiewicz was suppressed in the bud, and in the same year a rising of the Ruthenian peasants against their nobles in East Galicia gave a pretext for destroying the republic of Cracow, which was merged in Galicia. A better day seemed to dawn with the accession of Alexander II.; the government of Prince Michael Gortchakoff was milder than that of Paskevitch, and many emigrants returned home. During a visit to Warsaw (April 1856) the emperor counselled the Poles to cherish 'no dreams' of independence. But the flame of patriotism was not yet extinct. In the winter of 1860-61 the popular feeling began to find expression in sorrowful church services, and almost the whole nation went into mourning. On the 28th June 1862 the Grand Duke Constantine was appointed viceroy, with the Marquis Wielopolski as 'civil governor,' and Russia hastened to appease the people by a milder rule. In vain, from June 10 August repeated attempts were made to assassinate the Russian leaders, and the Government forthwith instituted an arbitrary conscription to draft off the 'revolutionary element.' A secret 'national government' was formed, whose 'hanging gentlemen' were implicitly obeyed, and a rising took place which was not wholly put down till January 1864, by General Berg, acting in concert with Muravieff in Lithuania, and Kauffmann in Volhynia. Then followed a general banishment of the nobles and confiscation of their estates. The peasants, freed from their obligations to the nobles, in 1863 in Lithuania and Volhynia, and on the 2d March 1864 in P. proper, received their farms from the Russian Emperor, and paid taxes to the exchequer of the empire. To break the power of the clergy, the monasteries, 114 in number, were abolished, and their estates confiscated (November 8, 1864), the direction of the Catholic Church in P. was transferred to St. Petersburg, and the bishops were forbidden to hold direct communication with the Pope. Russia now used every means to diffuse the Russian language in P., making it the only language recognised for instruction in the common schools, and completely Russianising the University of Warsaw. Gradually the smallest branches of the Polish administration were placed (1867-69) under the central authority of Russia, and with the removal of the supreme courts in 1876 vanished the last faint gleam of national individuality. According to Brachelli, the Polish nation now numbers 9,700,000 souls; of whom 4,772,000 are under Russia, 2,463,000 under Austria, and 2,432,000 under Prussia. See Bronikowski, *Die Geschichte P's bis 1825* (4 vols. Dresden, 1827); Röpell & Caro, *Geschichte P's bis 1855* (4 vols. Gotha, 1840-75); Rulhière, *Histoire de l'Anarchie de Pologne* (4 vols. 1807); Lelewel, *Geschichte P's* (2d ed. 1847); Spazier, *Geschichte des Aufstands 1830-31* (3 vols. 1832); Duchinski, *La Moscovie et la Pologne* (Constantinople, 1835); Von Smitt, *Suwarow und P's Untergang* (Leips. 1858); Ssolowjow, *Geschichte des Falles von P.* (1865); Bulle, *Geschichte der neuesten Zeit* (1875); Röpell, *P. um die Mitte des 13. Jahrhunderts* (Gotha, 1876); and E. von der Brüggen, *Polens Auflösung Kulturgeschichtliche Skizzen aus den letzten Jahrzehnten der Polnischen Selbstständigkeit* (Leips. 1878).

The Russian province of P., till January 19, 1874, a distinct part of the Russian Empire with a separate administration, has from that date been called the General Government of Warsaw, and placed on the same footing with the rest of Russia. Its area of 47,101 sq. miles (one-fourth forest, lakes, and swamps) has (1872) a pop. of 6,276,575 (65 per cent. Polish, 13 per cent. Jews, 11 per cent. Russians, and the rest Lithuanians or Germans), and is divided into ten governments—Warsaw, Kalisz, Piotrkov, Radom, Kielce, Lublin, Siedlce, Plock, Lomza, Suwalki. It is a fruitful plain, watered by the Vistula, with its tributaries the Pilica, Bug, and Wieprz. Agriculture is the chief occupation. In 1872 the corn reaped in P. amounted to 14,741,430 qrs.; the potato crop to 118,108,709 bushels. The industries include the weaving of woollens, linens, and cottons, brewing, distilling, and the manufacture of leather, oil, sugar, and wax. In 1872 the exports of P. (chiefly timber, wheat, rye, wool, swine, woollen fabrics, hides and leather, flax, metals, horses, bristles, oil-seeds, cattle, bones, and saws) were valued at £9,700,490, and imports (mainly raw cotton, machinery, metals, salt, woollens, hardware, petroleum, liquors, cottons, fish, linens, colours, fruit, and silks) at £15,821,253. The customs amounted to £1,329,971. At the last census 77 per cent.

of the pop. of P. were Roman Catholics, 51 per cent. Protestants, and 49 per cent. of the United Greek Church; but since the rising of 1863, Russia has forced thousands to forsake the Roman Catholic for the "Orthodox" Greek Church.

Polar Expeditions. The prevailing ideas in Western Europe of the splendour and exhaustless wealth of India were revived and confirmed by the glowing tale of Marco Polo in the 13th c., and in the discovery of routes to El Dorado a task was provided for a race of practical, enterprising men, quickened by the spirit of the Renaissance. By the beginning of the 16th c. the Portuguese had discovered the sea passage to India round the Cape of Good Hope, and the Spaniards that round S. America, but both these routes were guarded by a strict monopoly. Thus excluded from the East, England became eager to find a route for herself, and Sebastian Cabot in 1496 inaugurated the long search for a North-West Passage. The gradual discovery of such a route, and of a similar route to the East along the N. coast of Europe and Asia, is traced in the article NORTH-EAST AND NORTH-WEST PASSAGES. The present article is confined to the consideration of expeditions made for the purpose mainly of exploration in the Arctic regions. The land surface of the Arctic region is much greater than that of the Antarctic, and the former has, chiefly on that account, a higher temperature. In both regions the sea teems with life, but in the Arctic region alone, land animals, such as the bear, wolf, reindeer, musk-ox, and Arctic fox, are scattered over the frozen surface. Birds are numerous in both regions, and, strangely enough, are found in even greater number and variety in the severer region of the S. A hardy vegetation, including, in summer, beautiful flowers, extends beyond the Arctic circle, but in the opposite region no tree grows further S. than about lat. 56°. That the land around both poles was formerly covered by tropical or semitropical vegetation is proved by the discovery of fossil remains. To account for this phenomenon there are many theories, that of Dr. Croll being the last and perhaps most probable. According to Dr. Croll, the change in the eccentricity of the earth's orbit, combining with the precession of the equinoxes, produces in long lapses of time a slow secular change of climate, of warmer and colder cycles, alternating in the N. and S. hemispheres. However this may be, within the term of our actual knowledge these regions have been given over to icy desolation and long sunless winters, broken by three months of joyous summer, when the sun never sets.

Arctic Expeditions.—The early expeditions (first 1603) of Stephen Bennet were mainly for the purpose of moose-hunting. But in 1607 Henry Hudson was sent forth by the Muscovy Company to find his way, if possible, across the Pole. He got as far as lat. 81° 30' to the E. of Spitzbergen, when he was stopped by the ice, and put back to Nova Zembla. The three voyages of Jonas Poole (1610-12) added little to existing knowledge; but about the same time Thomas Marmaduke penetrated N. of Spitzbergen to lat. 82°. In 1614, Baffin, passing up Davis Strait, discovered the extension of that channel, to which he gave the name of Smith Sound. Next year Lotherby corrected some of Hudson's observations. With the single and abortive exception of Captain Wood in 1676, the English made no effort to reach the N. Pole for more than a century and a half. In the reign of George III. the Admiralty fitted out two vessels for purely scientific discovery, and under Captain John Phipps (1773) they coasted Spitzbergen to Cloven Cliff, then for about a month traced the edge of the field of ice, eventually found an opening which allowed them to reach lat. 80° 48', but were frozen in, and only extricated after the severest exertions. This failure, and the still greater one of Captain Cook in his attempt to advance N. through Behring Strait (1779), had the effect of so discouraging explorers, that the offer by Parliament of £5000 to the crew which should penetrate to within 1° of the Pole met with no response. In 1806, Scoresby advanced to lat. 81° 30' due N. of Spitzbergen, and in later voyages explored great part of Jan Mayen's Land and the E. coast of Greenland. The close of the war with France in 1815 was followed by a renewal of the attempt to find a N.W. Passage. In 1818 the *Dorothea* and *Teset*, under Franklin and Buchan, in an attempt to find a passage from Spitzbergen to the Pole, reached lat. 80° 37' amid great perils, and were forced to return on account of the injuries they received from the ice; while the *Isabella* and *Alexander*, under Ross and Parry, penetrated up Baffin Sea to the entrance of Smith Sound, and made many important discoveries. In

1827-33, Captain Parry (q. v.) and Lieutenant James Ross, commissioned by the Admiralty to attempt a passage to the Pole, made one of the most daring and adventurous voyages on record. They sailed in the *Hecia* on 25th March, anchored the ship in Hecla Cove, Spitzbergen, 20th June, and proceeded next day to push boldly N. in two specially constructed boat-sledges, the *Enterprise* and *Endeavour*. These vehicles when used as sledges were dragged by the men. The labour of traversing alternately fields of rough ice and dangerous pools, ice hummocks, and deep snow-slush, in thick fog or heavy rain, was terribly exhausting. Finding that they drifted S. as rapidly as they were advancing, Parry began the return journey 27th July, and reached the *Hecla* without mishap, 21st August. He had got as far as 82° 45', the highest latitude reached till 1875. We must here at least refer to the fatal expedition of Sir John Franklin (q. v.) on account of its great influence on Polar research. Within the last thirty years more than forty 'Franklin search expeditions' have gone forth from England and America, the last being that of Captain Allan Young in the *Pandora* in 1875. The first purely scientific expedition from America was that of the *Advance* under Dr. Kane, which left New York 30th May 1853, entered Smith Sound, and was abandoned after passing two winters in Rensselaer Bay. Kane saw from a height of 480 feet at Cape Constitution what he wrongly supposed to be an 'open Polar sea.' Dr. Hayes, who had accompanied Dr. Kane, again set out in 1860, made his winter harbour near Cape Alexander, and after forty-six days of dog-sledging, reached lat. 81° 35', where his progress was stopped 'by rotten ice and cracks.' He claimed to have demonstrated the existence of an open sea and the feasibility of exploring the entire region. On 3d July 1871 Captain C. F. Hall started in the *Polaris*, and, after a singularly prosperous voyage, entered Kane's 'open sea,' and attained lat. 82° 16' without 'obstacle of any kind.' The vessels wintered in the high lat. of 81° 38'. Captain Hall died 8th November from the effects of imprudent exposure. The *Polaris* party made many interesting discoveries regarding the abundance of animals (including the musk-ox), &c. The lowest temperature registered was 48° F. below zero. In June 1872 the vessel drifted with the pack ice into Baffin Bay, where suddenly she tore away before the wind, leaving nineteen castaways on the floe. The ship ran ashore on the E. side of Smith Sound, and the crew set sail S. in two boats constructed from her timbers. Happily both parties were rescued from their perilous position by whalers. In 1868 Captain Koldewey, in the *Germania*, a small vessel fitted out by Dr. Petermann, pushed N. along the E. coast of Greenland, was stopped by pack ice, and later reached the high lat. of 81° 5' to the N. of Spitzbergen. He then sailed down Hinlopen Strait, and finally reached Bergen safely in September 1868. The 'Second German Expedition,' as the voyage of the *Germania* and *Hansa* is called, took place in 1869-70. The ships made for the E. coast of Greenland, but 35 miles S. of Sabine Island, the place of rendezvous, the *Hansa* was wrecked on the ice, and its crew made a marvellous escape. They drifted S. on the 'ice-raft' or floe to lat. 61° 4' in 200 days, and eventually reached Friedrichsthal, a Moravian colony on the W. coast of Greenland, in two boats. The *Germania* wintered in lat. 74° 18', a few miles from land, and among the discoveries in the northerly journeys were 'an enormous layer of coal alternating with sandstone' in about 75°, and the Devil's Cape, a reddish wall 3280 feet high, in 76°, from whence, Payer believes, the Greenland coast trends N.W. to Smith Sound. During the spring journey the party reached their furthest point, 77° 1', on April 15. The *Germania* returned to Europe safely in September 1870. The Austrian Expedition of 1872-74, under Weyprecht and Payer, was one of the most important of all times. Grasped in the ice in lat. 76° 32', the *Tegethoff* drifted slowly N. from Nova Zembla, and (30th August 1873) sighted land in 79° 43' F. The winter of 1873-74 was devoted to the exploration of the new country, which was named Franz-Joseph Land (q. v.). In May 1874 the crew abandoned the *Tegethoff*, and dragged the boats across the ice to Barentz Island, then along the coast of Nova Zembla, and were rescued in an exhausted state by the Russian schooner *Nikolai*. The last and greatest expedition is that of the *Alert* and *Discovery*, under Captain George S. Nares, which left Portsmouth 29th May 1875. Advancing up Smith Sound, the *Discovery* was left in Lady Franklin Sound, while the *Alert* was only closed in (16th September 1875) after attaining lat. 82° 27'

on the shores of the Polar Sea, a point far north of that gained by any ship before. In the spring various sledge parties carried on the work of exploration, the chief one being that under Markham and Parr, which advanced to the high lat. of $83^{\circ} 20' 26''$, or to within 400 miles of the Pole. The results of the expedition, generally, were that the Polar Ocean is apparently a 'sea of ancient ice,' and is certainly not an 'open sea,' and that Europeans may safely winter in a climate where the most intense cold known prevails. The sledges explored the fringe of the frozen ocean over 50° of longitude, and added vastly to our knowledge of Arctic physiography. Nares concludes that it is impossible either to carry ships further N. in Smith Sound, or from any attainable position in the Sound to advance nearer the Pole by sledges. The vessels were safely extricated, and arrived at Disco 25th September 1876. A new Dutch Arctic Expedition left Amsterdam for Spitzbergen in May 1878, and the American Howgate Expedition started in July 1878. See Sir John Richardson's *Polar Regions* (Edinb. 1861), Smith's *Arctic Expeditions from British and Foreign Shores* (Edinb. T. C. Jack, 1877), and Dr. Petermann's articles in the *Mittheilungen* for recent years. For expeditions in the Antarctic regions, see SOUTH POLAR RESEARCH.

Polarisation is a term applied to a variety of distinct physical phenomena, in all of which, however, a certain *directedness* is implied. Thus the polarity of a magnet is a kind of P., and perhaps the most familiar of all and the easiest to recognise. Here we have two ends, called poles, possessing opposite properties, and the same peculiarity is possessed by solenoids or helices of conducting wire traversed by currents, and through them may be extended to rotation of bodies generally. In the same way a rectilinear current, regarded as the seat of magnetic action and the cause of the existence of a magnetic field, is also polarised. The word P., however, is rarely used but in two connections, which shall be considered in succession.

1. *Polarisation in Electrolysis*.—When a current is passed through an electrolyte, decomposition is known to take place. For instance, if the poles of a Daniell cell are connected to two pieces of platinum, which act as the electrodes to a quantity of acidulated water, the oxygen is given off at the electrode which is connected with the copper or positive pole, and the hydrogen at the electrode which is connected with the zinc or negative pole. Now platinum and indeed all metals have a remarkable power of condensing gases on their surface, and consequently not all the hydrogen and oxygen formed is given off. Some remains attached to the surface of the electrodes, so that now these electrodes can no longer be regarded as similar. The one is coated with hydrogen and the other with oxygen; and the electrolyte with its electrodes becomes in fact the source of a galvanic current, which acts in a direction contrary to the original current. This is proved by simply throwing the electrolyte into a galvanometer circuit, when a deflection is observed which gradually diminishes, thus indicating a dissipation of the P. When the original current is kept flowing constantly through the electrolyte, its intensity is of course diminished because of the contrary current due to P. As the current is continued the P. tends to reach a finite value, and the nearer the P. is to its maximum, the quicker is the dissipation when left to itself. It is this P. which renders experimental investigation into the electric resistance of liquids so difficult, and which is the great cause of the variation of resistance in simple cells. Exactly similar phenomena are observed if a current is sent through a dielectric like india-rubber or glass. The glass, however, must be at a temperature of 100° C. or higher, since for low temperatures it is a non-conductor; but these substances, though solid, appear to be true electrolytes, or at all events may be regarded as acting as such. See Clerk Maxwell's *Electricity and Magnetism*, vol. i.

2. *Polarisation of Light*.—If a ray of ordinary light be transmitted through a thin slice of the semi-transparent mineral tourmaline cut parallel to the axis, it becomes what is called polarised. Polarised light, however, cannot be distinguished by the eye from ordinary light; and the only apparent change in the transmitted beam will be a slight colouring in consequence of the natural tint of the crystal employed. That the light has not the same properties after transmission which it had before, is proved by transmitting it through another similar slice of tourmaline. It is then seen that when the slices have a certain relative position to each other, there is no light whatever transmitted. By rotating either, so as to alter their relative

positions, the combination will become transparent, and the transparency will increase, as the rotation is continued, until it reaches a maximum, when the transmitted light will be of the same intensity as if it had been transmitted through one piece of tourmaline equal in thickness to the two taken together. If the rotation is still continued, the light will begin to fade until it reaches its minimum again, until it becomes completely extinguished. By still continuing the turning the same cycle will take place—transparency and opacity alternating with every intermediate stage. Each maximum and minimum recurs after rotation through 180° , or two right angles; while rotation through one right angle is accompanied by a change from maximum to minimum, or from minimum to maximum. It is clear, then, that light passed once through the tourmaline, has completely changed its character. It is no longer symmetrical about an axis, since it passes similarly through a second piece of tourmaline only when the latter has a certain position. Rotate this tourmaline through one right angle, and the light is unable to pass. There is maximum transmission when the tourmalines are set so as to have their axes parallel; there is minimum transmission when these axes are perpendicular to each other. Tourmaline then polarises light; but to recognise this P. it is necessary to have two pieces of apparatus, the one to polarise and the other to analyse. In the case described, the first piece of tourmaline is the polariser; the second piece, the analyser. The above experiment shows that a polarised ray of light is unsymmetrical round an axis; it has, so to speak, *sides*, and in this differs from ordinary light. According to the now universally accepted undulatory theory, light is regarded as a form of radiant energy, transmitted in undulations through the all-pervading ether. These undulations are supposed to be caused by vibrations taking place in planes perpendicular to the ray. In ordinary unpolarised light the vibrations take place in all possible directions perpendicular to the axis of the ray. In polarised light, such as we get by transmission through tourmaline, the vibrations are executed all in one plane. Here we have what is known as *plane P.*, to be distinguished from other kinds to be considered later. And now, upon this hypothesis, a very simple reason is afforded for the complete cutting off of the light when the tourmalines are set so as to have their axes at right angles. In whatever position the second tourmaline is, it will act upon the already polarised ray exactly as the first tourmaline did upon the ordinary light. It will make the vibrations take place in a plane definitely fixed with respect to itself, it will simply transmit the portions of the vibrations which are resolved into this plane, and will therefore transmit none when this plane is perpendicular to the original plane of vibration. Such is the general explanation of plane P. Experiment shows that reflected light is always partially polarised. It may be simply demonstrated by looking at reflected light through a piece of tourmaline and rotating the crystal, when a varying intensity will be observed. The amount of P. depends upon the angle of incidence, but attains a maximum for a definite angle which differs for different media. Brewster proved by experiment that this *polarising angle* is such that its tangent is equal to the refractive index of the medium; or, in other words, the reflected ray and refracted ray are at right angles to each other when the incident ray makes the polarising angle with the perpendicular to the surface. The same law can be deduced from theory. Not only, however, is the reflected ray polarised, but, as might have been expected, so is the refracted ray. It is of course only partially polarised, but by refracting it, with accompanying reflection, through a series of thin parallel plates, it will, so to speak, undergo continual sifting and emerge highly polarised. The plane in which a plane-polarised ray, incident at the polarising angle, is most copiously reflected, is called the plane of P. of that ray. When a doubly-refracting crystal such as Iceland spar (see REFRACTION) is traversed by a ray of light, the ray, except when parallel to the optic axis, is divided into two, known as the ordinary and extraordinary rays. The former is refracted according to the ordinary law, the latter not so. Both, however, are polarised. In order to study the P. successfully, one must be thrown completely out of the field. This may be effected in various ways, but the most common method is by the use of a Nicol's prism, which is merely the two halves, obtained by splitting a rhomb of Iceland spar along a diagonal plane, cemented together again by Canada balsam. The ordinary ray is then totally reflected at the surface of the Canada balsam, while the extraordinary ray is allowed to pass.

When a plane polarised ray of light is reflected at a surface it becomes elliptically polarised—that is, the vibrations take place no longer in straight lines, but in ellipses whose axes are equal and parallel. The explanation of this is as follows. The incident polarised ray may be decomposed in two directions, namely, in the plane of incidence, and perpendicular to that plane. The effect of reflection, however, is to alter the phases of these portions in opposite ways, so that the one set of vibrations is accelerated and the other retarded. After reflection, then, we have a combination of two harmonic motions of equal period but of different phase, and the result is, in accordance with known kinematical law, elliptical motion. Should the phases differ by a quarter of a period, the ellipse will become a circle, and we shall have circularly-polarised light, provided that the amplitudes are equal. This latter condition is effected when the plane of P. of the incident ray makes, with the plane of incidence, an angle of 45° . *Fresnel's rhomb* is a parallelepiped of glass, so cut that a ray of plane polarised light entering perpendicularly by one of the sides, suffers two internal reflections, and emerges perpendicularly from the opposite face as a circularly polarised ray. Transmission through a second rhomb reduces the ray again to the plane polarised condition; but the plane of P. has been rotated through one right angle. This rotation of the plane of P. is a phenomenon which always accompanies the direct transmission of a plane polarised ray through certain media; but in such cases the amount of rotation is a function of the thickness of the medium. Such a medium is rock-crystal, and Biot established by experiment that the rotation is always proportional to the thickness, and increases, *ceteris paribus*, with the refrangibility of the ray. It is this which accounts for the beautiful colours which the polarised ray presents when viewed through an analyser. Solutions of sugar, oil of turpentine, and certain other liquids have the same rotating effect, though not to such a marked extent. All such substances are grouped in two classes, according to the direction in which the rotation takes place. Ordinary quartz and oil of turpentine give right-handed rotation, *i.e.*, in the direction of the hands of a watch; solution of uncrystallisable sugar, and the kind of quartz known as left-handed, gives the rotation in the other direction. These phenomena have been accounted for by taking a plane-polarised ray to be equivalent to two circularly polarised rays α , which the vibrations are in opposite directions, and then supposing that these oppositely circularly polarised rays are transmitted with unequal velocities through the medium. One of them will then be retarded by an amount proportional to the thickness traversed, and it can be shown mathematically that this retardation fully accounts for the rotation of the resultant plane P. Similarly is explained the rotation of the plane of P. by the action of magnetism. The undoubted rotatory character of magnetic action is supposed to accelerate the one circularly-polarised ray and retard the other.

If between a polariser and analyser set so as to permit no light to pass, a plate of a doubly refracting crystal, such as mica or selenite, is introduced, a portion of the light will at once pass, except for two positions of the interposed plate. These positions are when the principal section of the crystal coincides with the plane of P., or is perpendicular to it, and there is maximum illumination for positions midway between these. Should the interposed plate be very thin, a most gorgeous combination of colours results. Rotation of the crystal alters simply the intensity of the light, the tints remaining the same. If, however, the crystal is fixed and the analyser turned, the light will pass through every grade of tint into the complementary colour. Here we have interference of polarised light. Experiment and theory alike agree in showing that two rays of light polarised in the same plane interfere and produce fringes, as two rays of common light do, and that the interference diminishes as the planes are more and more inclined to each other, until when they are perpendicular there is no interference. The splendid optical effects which interference of different kinds of polarised light affords cannot here be entered upon. For a popular description of them the reader is referred to Spottiswoode's *P. of Light* ('Nature' series, 1874). The theory is very fully explained in Lloyd's *Wave Theory of Light* (3d ed. 1873).

Polder (Dutch, probably allied to the English 'pool'; Ger. *pfuhl*, 'a pool' or 'marsh'), or **Kooge**, a name given in Holland to reclaimed lands which lie below the level of the sea or adja-

cent river. They are the beds or lakes or marshes out of which the water has been pumped—in the case of the smaller P. by means of wheels driven by windmills, in the case of those of large area by powerful steam pumping-engines. They would soon return to their original condition were the pumps withdrawn, or were the dykes by which they are surrounded to give way. The polders of Holland are extremely numerous (S. Holland alone contains over a thousand), and some of them lie as low as 40 feet below high-water mark. In the Schermermeer P., N. Holland, there are four drainage levels. The largest, in which the work of drainage is completed, are those of the Haarlem Lake (q. v.) and Boemster (near Edam in N. Holland), measuring 15 miles in circumference. But the largest ever planned is now in construction out of the Zuyder Zee. The preliminary work in this vast undertaking is the erection of a dyke or wall of partition from Enkhuizen to Kempen, via the islands of Urk and Skokkland, a distance of 25 miles. The dyke has a breadth of 164 feet at its base, and is to rise 26 feet out of the water.

Pole and Polar. To fix a point in space requires three numbers. These three numbers may be taken with reference to three fixed planes, which are usually rectangular. The distances of the point from these planes are the co-ordinates of the point, and when given, completely determine the position of the point. In the method of polar co-ordinates, the point is fixed by a distance and two angles. When the distance of the point from the origin or P. is given, the point loses one of its degrees of freedom, and may be anywhere upon the surface of a sphere. If, however, we know the altitude of the point above a plane fixed in space and passing through the P., and its azimuth with reference to a straight line fixed on that plane, the position of the point is completely fixed. For many problems, especially in astronomy, polar co-ordinates are much more convenient than rectangular co-ordinates. In quaternion analysis, the three polar co-ordinates are combined in one symbol, the *vector* drawn from the origin to the point. In modern geometry, the term P. has a totally distinct meaning. From every point two tangents, real or imaginary, can be drawn to a curve of the second order. In all cases the line joining the points on the curve where the tangents touch is a real line, and is called the polar of the point. Conversely the point is called the P. of the line. If the curve of reference be a circle whose centre is O, the polar of any point P is the perpendicular which intersects OP, or OP produced in the point Q such that the product OP.OQ is a constant, the square namely of the radius of the circle. The polar of a point which lies upon the polar of another point passes through the latter; or, if A be a point in the polar of B, B is a point in the polar of A. The curve formed by the ultimate intersections of the polars of the points upon a given curve is the reciprocal polar of the latter curve. One particular case of this is the reciprocal polar of a given circle, which is always a conic section whose directrix is the polar of the centre of the circle. It is of importance as being the case of the Hodograph (q. v.) for motion under the action of the force of the inverse square. The method of reciprocal polars, by which one theorem regarding lines and points leads directly to a related theorem regarding points and lines, is a development from the theorems given above. See Salmon's *Conic Sections* for detailed discussion concerning them.

Pole, Reginald, son of Sir Richard P. and Margaret, Countess of Salisbury, was born 3d March 1500, at Stourton, Staffordshire. He received his education first of all in a convent at Sheen, from which he passed to Magdalen College, Oxford, to the tuition of Latimer and Linacre. Having graduated B.A. in his fifteenth year, he was speedily advanced in the Church by Henry VIII., to whom he was related. P. next took up his residence at Padua, and for five years associated on the footing of a prince with Erasmus, Bembo, Sadoletto, and other scholars of European reputation. In 1525 he came back to England, where his refinement and scholarship made a great impression. Henry VIII., now bent on obtaining a divorce from Catharine of Aragon, was anxious that his kinsman should assist him. P. seems, if we may judge from a recently discovered letter, to have at first gone heartily into the matter, but he was at heart a staunch Churchman, if not a man of strong intellect or character, and he soon drew back, retiring to the Continent. In 1531 he was offered the Archbishopric of York as the price of his consent, but declined to give it. Having

published an attack on the king in a Latin treatise, *De Unitate Ecclesiastica*, it was answered by the seizure of his relatives—the aged Countess of Salisbury, the Marquis of Exeter, and Lord Montague—all of whom were brought to the block. On the 22d December 1536, Paul III. created him a cardinal at Rome, and in the following year he acted as legate before Karl V. and François I. In 1545 he performed the duties of legate-president at the Council of Trent, and in 1549 was all but appointed to the Papal chair. He returned to England, November 24, 1554, as Roman plenipotentiary, with the commission of restoring the realm to the Catholic faith, and under Queen Mary became Archbishop of Canterbury and Chancellor of the Universities of Oxford and Cambridge. He died of a quartan fever, 18th November 1558. P. was a finished classical scholar, and has left models of good latinity in his *Reformatio Angliæ*, *De Concilio*, and *De Justificatione*. 'Everything,' says a writer in the *Saturday Review* (16th February 1878), 'that comes to light about P., is favourable to his moral character and uprightness of intention, but everything also seems to indicate a feebleness of intellectual power in which the last Cardinal of Canterbury is contrasted most distinctly with the last Cardinal of York.' See Philipps' *Life of Reginald P.* (Oxf. 1764), and Calendar of State Papers and MSS. existing in the Archives and Collections of Venice, &c., vol. vi. Part 1, 1555-56, edited by Rawdon Brown, published under the sanction of the Master of the Rolls (Lond. 1877).

Pole-Axe, a kind of battle-axe having a long pole shaft, carried by mediæval foot soldiers. The axe-head varied much in form among the different nationalities; sometimes it combined a spear point and hammer. The Bayeux tapestry shows the English soldiers armed with plain pole-axes. The Lochaber axe—the national weapon of the Scottish Highlanders—and the Lowland Scottish Jedburgh axe, in use from the 16th to the 18th c., were noted varieties of the P.-A. The short hatchet used in the navy in resisting boarders, cutting ropes, &c., also bears the name P.-A.

Polecat (*Putorius fœtidus*), a species of Carnivorous animals belonging to the *Mustelide* or weasel family. It has thirty-four teeth, and ears of moderate size. The body is about 18 inches long. Like other members of its family, the P. has anal glands, placed near the root of the tail, the secretion of which has a most offensive odour, on account of which it is known as the 'Foumart' or 'Foul marten.' The name 'Fitchet' is also given to it. The under fur is close, and of a pale yellow colour; the upper fur is composed of long brown hairs. The P. is very destructive to poultry-yards, but its food appears to be of a very miscellaneous kind, and includes frogs, fishes, and the smaller quadrupeds. The nest occurs at the end of a burrow, and from four to five young are produced at a birth. The outer and longer hairs of the fur afford the materials from which the finest artists' brushes are made.

Polemoniacæ is a natural order of dicotyledonous annual or perennial herbs, or rare shrubs with entire or divided leaves, usually white or blue flowers in terminal cymes, and fruit a three-celled capsule. It numbers about 100 species, chiefly met with in temperate and arctic regions, and especially plentiful in W. America. The properties are unimportant, but many have been long cultivated in gardens for their showy flowers; e.g., different species of *Phlox*, *Gilia*, *Polemonium*, *Lamnanthes*, *Leptociphon*, &c., while several of the genus *Cantua*, from Peru, and the climbing tendrilled *Cobæa scandens* are ornamental greenhouse plants. The seeds of various *Collomia* when moistened under the microscope form beautiful objects. Jacob's Ladder (q. v.) represents the order in Britain.

Polenta, an article of food of Italian origin prepared from the meal of Indian-corn boiled to a stiff paste or porridge. It is allowed to cool, and, before using, is cut into slices nearly an inch thick, which are thickly sprinkled with Parmesan cheese, then saturated with olive oil or melted butter, and baked for half an hour in an oven, and served hot. The fine meal of Indian-corn is called *polentina*, and in the United States the porridge of Indian-corn, under the name of *nush*, is a common article of diet.

Poles, Geographical, of the earth, are the extremities of its axis of rotation, and are situated 90° from every point of the equator. They are not coincident with the magnetic poles,

which are the points where the magnetic meridians meet. See TERRESTRIAL MAGNETISM.

Pole Star, or **Polaris**, is a star of the second magnitude, so named because it is the nearest conspicuous star to the celestial north pole, or the point in the sphere of the heavens which corresponds to the earth's north pole.

Polewig (*Gobius minutus*), a species of Teleostean fishes belonging to the Gobies, and distinguished by its small size and transparent grey colour, varied with black dots and dark patches.

Police (Lat. *politia*, Gr. *politeia*, 'civil government'; from *polis*, 'a city') are officers in town and country whose business it is to preserve the peace and to prevent and detect crime. In London, P. justices are stipendiary magistrates, created, except those in Bow Street Office, by statute in 1792. Their number is limited to twenty-seven. They are appointed by the Home Secretary, and are under his control. They must be barristers. Their duties are judicial, and consist in the examination and commitment or discharge of persons brought before them by the constables, under the control of the P. commissioners. One magistrate is required to attend at each of the P. courts every day except Sunday, Christmas Day, Good Friday, and any public fast or thanksgiving day, from ten in the morning till five in the afternoon, and at such other times as may be directed by the Home Secretary. The following is a summary of the chief regulations of the P. Acts within the metropolitan districts. All houses of public resort are, for the prevention of disorderly conduct, placed under the same regulations as drinking-houses. Unlicensed theatres are prohibited. Reputed gaming-houses may be forcibly entered, and all present taken into custody. Obstructions and nuisances in thoroughfares are prohibited. Street musicians must leave a particular locality when required to do so by a householder. The P. may act on the river, and at any time go on board of a vessel to observe the conduct of persons on board. They may apprehend, without a warrant, any one whom they suspect of having committed, or of being about to commit, a felony, misdemeanour, or breach of the peace, or any one loitering about, who cannot give a satisfactory account of himself. They may stop and detain till due inquiry be made any vehicle removing furniture between 8 P.M. and 6 A.M. The Act 2 and 3 Vict. c. 93 empowers the Justices of any county, in quarter sessions, to make application to the Secretary of State for the establishment of a county and district constabulary. The provisions of this Act are enlarged and rendered more effectual by 19 and 20 Vict. c. 69 and 22 and 23 Vict. c. 32. Where constabularies have been established in divisions of counties, they may be consolidated and a chief constable appointed for the county. County constables are to have the same powers and duties in boroughs as borough constables have in counties. In Scotland, a system of P. has been established in Edinburgh, Glasgow, and other considerable towns. The expense of those establishments is provided for by an assessment on the householders, and the superintendence of the whole is intrusted to commissioners chosen by the ratepayers.

In the army there is a body of military P. consisting of steady and intelligent soldiers who act under the orders of the provost-marshal, and whose chief business is to arrest all who infringe discipline. In Ireland and in some European countries the civil P. possess a military organisation.

Policy of Insurance is a written obligation specifying the nature of the risk insured against, and the premium of insurance. In Marine Insurance (see under INSURANCE) those who undertake the obligation put down their names and the sum for which they respectively become bound, and it is from thus underwriting the obligation that they are called *underwriters*. The word P. is an Italian corruption (*polissa*) of the Gr. and Lat. *polytycha* ('many-fold'), a name given in the Middle Ages to memoranda written on several tablets.

Polignac, a French family which traces its origin to the 5th c., but whose name only emerges in history towards the end of the 9th.—Melchior de P., son of the sixteenth marquis, was born at Puy-en-Velay, 11th October 1661, studied at Clermont and Harcourt, where he became steeped in the Cartesian system. Having entered the Church, he soon became known as a polished and cultivated man of the world, was present (1689) at the Roman Conclave when Alexander VIII.

was elected, and again (1692) on the election of Innocent XII. In 1695 he went to Poland, where he diplomatised in favour of Prince de Conti, but without ultimate success. He then retired to the Abbey of Beaupré, and during four years devoted himself to the composition of an ambitious poem entitled *Anti-Lucratus*, which ultimately took shape in nine books, with a thousand to thirteen hundred verses in each, and even then was not completed. He recovered the lost favour of Louis XIV. in 1702, went to Utrecht in 1712 as French plenipotentiary, assisted at three Papal Conclaves, and from 1721 to 1730 watched over French interests at Rome. He died at Paris, April 3, 1742. See Faucher's *Histoire du Cardinal de P.* (2 vols. Par. 1772). Among the friends of Marie Antoinette (q. v.), and Louis XVI., who by their extravagance and folly largely helped in alienating the populace of Paris from royalty, were **Yolande Martine Gabrielle de Polastron, Duchesse de P.** (born 1749, died 1793), and her husband, **Jules, Duc de P.** (died 1817). His eldest son, **Armand Jules Marie Herardius**, who received the grant of an estate from the Emperor of Russia in Lithuania as an emigrant, became under Louis XVIII. a field-marshal, and sat in the House of Peers. His brother, **Auguste Jules Armand Marie, Prince de P.**, born at Versailles, 14th May 1780, was an intimate friend of the Comte d'Artois, afterwards Charles X., and received from the Pope on account of his ardent clerical policy the title of 'Prince.' He became ambassador at St. James's (1823), was Premier in the last Bourbon Ministry, and issued the famous and fatal decrees which resulted in the fall of Charles X., and was imprisoned in the fortress of Ham until the November amnesty of 1836. He died at Paris, 2d March 1847.

Polish Language and Literature. Polish, which, with Czech and Wendish, forms the Western branch of the Slavonic family of speech, was once the language of all the country extending between the Elbe and Dnieper, but is now restricted to Russian Poland, Posen, Galicia, parts of Silesia, Eastern Prussia, and Pomerania, and to the villages scattered over the Siberian steppes, to which a paternal government has banished its Polish kinsfolk. Even within these narrow limits Russian and Prussian statesmen are doing their utmost to stamp it out, and it is mainly to the efforts of the refugees who throng the capital of Europe that Polish owes its survival as a literary dialect. Its vocabulary has been enriched by the incorporation of Latin, German, and Russian elements, and its grammar bears many points of resemblance to the Latin. Thus, like Latin, it has no article, and possesses two conjugations and seven cases, the locative being quite distinct from the instrumental. It has, however, three numbers and three genders. Polish employs the Latin alphabet with certain modifications, *v* being represented by the Teutonic *w*, whilst double consonants are of frequent occurrence—*cz*, *dz*, *rz*, and *sz*. There are Polish grammars by Poplinsky (9th ed. 1869) and Malecki (Lemb. 1863); German-Polish dictionaries by Mrongovius (Danz. 1835, Eng. ed. Berl. 1851) and Boocky-Arkossy (Leips. 1865-68); and an English-Polish dictionary by Chodzki (Berl. 1874). See Miklosich, *Vergleichende Grammatik der Slavischen Sprachen* (4 vols. Vien. 1852-74); and Schafarik, *Geschichte der Slavischen Sprache und Literatur nach allen Mundarten* (Prague, 1869).

The Polish literature, though perhaps the most important of any Slavonic people, is deficient in the quality of originality. Ostrowski divides it into four epochs—that of the monks, from the 10th c. A.D.; that of the knights, from 1500; and that of the people, from 1800 down to the present day. The monks, who in the 10th c. brought Christianity to Poland, wrote hymns in the language of the country, and the most ancient monument of Polish—atill intelligible to an unlettered peasant—is the *Bogorodzica* ('God's Virgin Mother'), ascribed to Bishop Adalbert (died 997). But with Christianity came Latin, which for centuries choked the growth of a national literature, and was the language of the chroniclers from the 12th to the 16th c., from Martin Gallus (died 1150) down to Jan Dlugosz (died 1480). The abandonment of Latin by the Diets and the establishment of a representative form of government gave a great impulse to the national idiom, and paved the way for Poland's golden age of literature, the chivalrous reigns of the two Sigismunds (1507-72), who were to their country what Louis XIV. was to France. To this period belong one Catholic and two Protestant translations of the Scriptures into Polish, the hymnal of Seklucyan and Trzycki, the

Memoirs of Réj, the 'Polish Montaigne' (1515-68), the poems of Kochanowski, Grochawski, and Janitius, the histories of Cromer and Bielski, and the metaphysical writings of Skarga, Herbut, &c. This renaissance was followed, under Jesuit influences, by a slumber which lasted down to the present century, when Poland rang with the sudden cry of *ojczyzna*—Fatherland. The 18th c. attempt of the Piarists, the Jesuits' opponents, to create a literature based on the models of French Classicism, had borne but scanty fruit in Krasicki's *Myszeis* ('War of Mice') and *Monomachia* ('War of Monks'), in the satires of Wegieraki and Trembecki, and the love-songs of Kniaznin; and the people's heart was first truly stirred by Woronicz (died 1829) in his *Sibylla*, the epic of Poland's history, and by Niemcewicz, the national poet, dramatist, novelist, and historian (died 1841). Greater than these, however, was Adam Mickiewicz (1798-1850), the leader of the victorious Romantic school, and author of the epic *Konrad Wallenrod* and *Pan Tadeusz*, who counted among his followers the lyricists Brodzinski, Odyniec, and Kraszewicz, with the so-called 'Ukrainian poets' Zaleski, Malczewski, and Goszczynski. Of Polish writers living or lately dead, the chief in the field of poetry are Asnyk, Belza, and Krasinski, author of the *Nieboska Komedia* ('Undivine Tragedy'), and in that of fiction, Kzewuski and the renegade Czajkowski; whilst as historians may be mentioned Icelwel, Lepkowski, and Szynski; as metaphysicians, Goluchowski, Supinski, and Libelt, founder of the 'philosophy of intuition'; and as philologists, Linde, Leslaw, and Rykaszewski. See Orchowski, *Poésies Polonaises* (2 vols. Gott. 1816-17); Chodzko, *La Pologne Historique et Littéraire* (3 vols. Par. 1834-47), and Mrs. Robinson ('Talvj'), *View of the Languages and Literature of the Slavic Nations* (New York, 1850).

Polishing Materials possess different degrees of hardness, hence their utility in the industrial arts in polishing metal, stone, glass, wood, &c. They are chiefly derived from the mineral kingdom, but a few animal and vegetable substances are also employed as P. M. for soft surfaces. For cutting and polishing gems and hard stones, diamond dust is employed, and next to that substance in hardness ranks alumina, which occurs in great purity as Corundum (q. v.), and Emery (q. v.), and is also the chief constituent of Rotten-stone (q. v.). Siliceous materials, as grits, Grindstones (q. v.), Hones (q. v.), Pumice (q. v.), Tripoli Powder (q. v.), and Bathbrick (q. v.), have varying applications in polishing; while for very smooth surfaces, metallic oxides, as Rouge (q. v.), and Putty Powder (q. v.), charcoal, chalk, cuttlefish bone, and other substances, finely pulverised, are extensively used, either in a dry state, or mixed with fat or wax to form a paste. Polishing wheels are usually made of wood covered with leather, and their surfaces are charged with a paste of a fineness adapted to the work in hand.

Polishing Slate, a kind of yellow or greyish-yellow slate employed in polishing metals, glass-lenses, &c. It is composed of diatomaceous matter, and is abundantly found in Bohemia and the Auvergne.

Political Economy, or Economics (Gr. *oikos*, 'a house,' and *nomos*, 'a law'), originally dealing with household thrift, gradually widening till it embraced the management of society (*polis*, 'a city' or 'state'), in recent times has become the science of the laws according to which wealth is acquired and used. The earliest work on economics we know of is *Eryxias*, or *About Wealth*, anonymous, about 427 B.C. Plato's writings (and especially Book ii. of the *Republic*) contain much discussion of economical questions; in Xenophon's *Economics* is a remarkable passage on division of labour. But Aristotle founded P. E. His *Ethics* deals with law for individual man; his *Politics*, with the relation of man to man in society; his *Economics*, with property and the rights connected with it. In Book ii. chap. i. of the last-mentioned work, the term 'P. E.' first occurs. From the time of Aristotle down to the 16th c. we have no reason to suppose that any systematic treatment of economics was attempted. The Italians were early in the field of modern inquiry. During the first few years of the present century appeared a collection of the entire works of the Italian political economists, in fifty octavo volumes, edited by Cusodi. Of the band of reformers represented in this edition, the first was Antonio Bandini of Siena, who addressed a memoir to the Grand Duke of Tuscany in 1737, recommending free-trade in corn, the granting of leases to

tenants, and the repeal of vexatious imposts, with the substitution in their place of a tax levied uniformly on all property, even that of the nobility and the church. Bandini's work was not published till 1775. Before that time Fernando Galiani of Naples had produced his treatise, *Della Moneta*, a great advance on the times, full of error as it is considered now. Then came another free-trade discourse, *Sopra i Bilanci delle Nazioni*, by Carli, 1771—a companion work to Pillo Verri's *Sulle Leggi Vincolante*. These writings breathe the same spirit of hostility to restriction in all its forms, but abound in crudities and absurdities of theory.

France, for interest in this subject, was little behind Italy. The Alps between the two nations fitly typify the mountains of flinty prejudice which had to be tunneled through. The earliest French work on economics is the *Traité d'Economie Politique*, by Montchrestien (Rouen, 1615). In 1662 Louis XIV. placed at the head of the finance department a man well instructed in the principles of economics—Colbert. In the early years of his ministry Colbert gave a great impetus to free trade; but later he favoured the mercantile system, a system which taught that a country should sell and not buy. To this system the name of *Colbertisme* was given by adult baptism: Blanqui has shown that it really originated with Karl V. and the Spaniards. Vincent Seignur de Gournay, a learned merchant, became Intendant de Commerce—a sort of President of the Board of Trade—in 1751 and for some time pushed a reforming policy finally overthrown as revolutionary—which, indeed, in the best sense it was. He maintained that government should protect the general community from the monopolising tendencies of classes, that it should protect a man in any investment of his capital not immoral, and that it should promote competition, trusting to the natural operation of men's interests for the increase of national wealth. Some years after Gournay had thrown up the reins of trade, Quesnay began to theorise. Not until an old and infirm man did he turn his attention to economics, contributing the articles 'Fermier' and 'Grains' to the *Encyclopédie*. In the second of these contributions he made his distinction between *produit total* and *produit net*—between the productiveness of agriculture and the unproductiveness (as he supposed) of other employments. In this article also, it is only fair to state, he advocated unrestricted commerce. The system of Quesnay—of the Economistes or Physiocrates—was a natural recoil from the mercantile system. The mercantile system had well-nigh ruined the country by proclaiming money the only riches; the Economistes returned to Sully's dictum, 'Labourage et pâturage sont les mamelles de l'Etat,' and supplemented this with their celebrated formula 'Acheter, c'est vendre; Vendre, c'est acheter.' They only erred in confining the term 'productions' to agricultural labour.

Perhaps the first treatise on Economics in England worthy of note is Thomas Muir's *England's Treasure by Foreign Trade* (Lond. 1664). Sir Joshua Child's *Brief Observations Concerning Trade* appeared in 1668. It was thought worthy of translation into French by Gournay, and threw out valuable hints on population, money, and monopolies. Sir Dudley North's *Discourse upon Trade* (1691) was aimed at national jealousies, and was really a prelude to the doctrines of free trade. The man who gave Adam Smith the clue to a philosophical treatment of economics was Hutcheson, Professor of Moral Philosophy in Glasgow. His explanation of Value, and Demand and Supply, has been little improved upon by Smith. Hume and Lord Kames also prepared Smith's way.

The appearance of the *Wealth of Nations* (1776) created a revolution in the science of Economics. In a few years it began to alter laws and treaties; it was translated into all the European languages; ministers of state quoted it. No other work ever effected so immediate and permanent a change in the legislation of civilised countries. Perceiving the error of the mercantile system, which regarded money alone as wealth, and the error of the Physiocrates, who found wealth only in the soil, Smith made labour the basis of his doctrine. The *Wealth of Nations* treats of 'the causes of improvement in the productive powers of labour, and the order ascending to which its produce is naturally distributed among the different ranks of the people; of the nature, accumulation, and employment of stock; of systems of P. E.; of the revenue of the sovereign or commonwealth.'

Two later economists of note in England, Malthus and Ricardo, developed doctrines Smith had prepared the way for, yet did not anticipate. In 1798 the former published anonymously *An*

Essay on the Principle of Population as it affects the Future Improvement of Society, but in subsequent editions his name was affixed. This treatise was called forth by an essay by Godwin in the *Inquirer*, and Godwin replied to it bitterly in the book entitled *Of Population*. The Malthusian doctrine is that population increases in geometric progression, while subsistence increases only in arithmetical progression. There are but three checks on this tendency to over-population—vice, misery (infant mortality and all disease), and moral restraint in marriage.

Ricardo's *Principles of P. E. and Taxation* appeared in 1817. His peculiar doctrines are those concerning rent and value. He declares that rent is caused by the transfer of cultivation from one sort of soil to another sort inferior to it. As soon as the first soil is insufficient to produce enough corn to satisfy demand, a second soil is brought under tillage; and only then is a rent drawn from the first. As to value, Ricardo maintains that the value of an article depends, not on the demand for it, but on the amount of labour required to produce it. J. S. Mill has to some extent adopted this view in denying that a demand for commodities is a demand for labour. Now that the doctrines of Free Trade developed by the economists and Adam Smith have assumed the form of natural laws, original teaching on Economics is not so much looked for. The best of recent French economists are J. B. Say, Sismondi, Blanqui, Chevalier, Bastiat, Rossi, Garnier, and Dunoyer. Of Italians may be mentioned Gioja, Beccaria, Poulet, Invrea, Mennechini. The principal Germans are Paelitz, Barth, Riedel, Bülow, List, Rau, and Hildebrandt. English writers are De Quincey, James Mill, Torrens, M'Culloch, Whately, M'Leod, Longfield, Scrope, Bailey, Burton, Cannan, Stirling, Price, Fawcett, Jevons, &c. See *Dictionnaire de l'Economie Politique* (2 vols. Par. 3d ed. 1864), Blanqui's *Histoire de l'Economie Politique* (4th ed. Par. 1860), both with good bibliographies, and an admirable little primer of P. E. by W. Stanley Jevons (Macmillan, 1878).

Political Offences. These may be divided into *major* and *minor* offences against the state. Respecting the former, see TREASON; MISPRISON OF TREASON; ATTAINDER; and under BILL, B. of Attainder. Regarding the latter, see COIN; COINING, LAW REGARDING; under CONTEMPT, CONTEMPT OF PARLIAMENT; MEETINGS SEDITIOUS; SEDITION and POLITICAL SOCIETIES. Applicable to both classes, see EXTRA-DITION.

Political Societies. The Act 39 Geo. III. c. 79 was directed against certain associations called societies of *United Englishmen, United Scotchmen, United Irishmen, &c.*, which were formed for purposes at that time considered treasonable. It prohibits members of societies from taking any oath not required by law, and makes various provisions to prevent secrecy of membership and procedure. The provisions of this Act are extended by 57 Geo. III. c. 19. The aim of these Acts being solely to prevent the formation of treasonable or seditious societies, their severe restrictive provisions are not likely to be enforced against any society, whether political or otherwise, unless it come under suspicion of being treasonable or seditious. 9 and 10 Vict. c. 33 provides that no one shall prosecute under the above-quoted Acts except the law officers of the crown.

Politics may be looked upon either as the science or as the art of government. It has to do with the business of governing, seeking the greatest happiness of those governed; it has also to do with the formation of governing bodies, with a view to their common weal.

In the first of these departments it embraces legislation, which means the making of positive law. But a general law issued by a governing body would be useless, were it not carried into practice on every occasion falling within its scope. Accordingly there must be established a distinction between the *legislative* and the *executive* powers of a government. An executive command is a special command issued in accordance with a law already passed. Such executive commands or acts are either administrative or judicial. A judicial declaration decides whether or not a certain person has been brought within the scope of a certain penal provision, or whether a certain person is possessed of a certain disputed right. In judicial proceedings, the Government functionary acts only at the motion of others. But in administrative proceedings the functionary may act spontaneously, and such proceedings are for the purpose of carrying a

rule of law into effect when there is neither a question of legal culpability nor a question of right.

A government is called a *monarchy* when it is vested in a single person. There are many degrees of this form, from despotism to limited monarchy, such as that of Britain. When the governing body consists of a few who acquire the ascendancy, whether hereditary or not, it is called an *aristocracy* or *oligarchy*. When the body comprises the majority of the nation, the government is called a *democracy*. These forms are often mixed.

Poliziano, Angelo, Italy's greatest poet between Petrarch and Ariosto, was born 24th July 1454, at Monte Pulciano, in Tuscany, where his father, Messer Benedetto Ambrogini, was a needy doctor of laws. He came as a boy to Florence, and was educated in the palace of Lorenzo de' Medici, studying Latin under Landino, Greek under Andronicus of Thessalonica, the Platonic philosophy under Ficino, and the Aristotelian under Argyropylus. He published Latin compositions in his fourteenth and Greek in his eighteenth year, a twelvemonth later edited Catullus, and about the same time composed his *Orfeo*, a combination of tragedy, pastoral, and opera, with its famous Mænad chorus. In the half-epic, half-idyllic *Giostra* (1477), P. sang how Giuliano de' Medici loved Simonetta, and carried off the prize in the tourney, a trivial theme enough, but one that our poet touched with matchless art and adorned with the rare scholarship displayed in his rendering of Homer into Latin hexameters, and Latin prose translation of Herodian. He also wrote scores of minor verses (*ballate*, *rispetti*, and *strambotti*); edited Justinian's *Pandects*, Ovid, Quintilian, and the younger Pliny; translated Plutarch's *Love Tales*, Epictetus, Alexander Aphrodisius, and selections from Moschus and Callimachus; and charmed the Renaissance scholars with his *Miscellanea* (1489), a series of studies on the classic authors. Lorenzo made him tutor to his sons, and he was professor of both Greek and Latin in the University of Florence, numbering amongst his hearers Reuchlin, Grocyne, Linacre, and the Portuguese Tessleras. Honours rained thick upon him—the flatteries of a pope, the citizenship of Florence, a canonry in the cathedral, the choice of any or every professorial chair. But Savonarola's prophetic thunders came to drown the merry strains of his *Canti Carnavaleschi*, his patron Lorenzo was dead, and P. himself, 'weeping early and late,' passed away at the age of forty, 24th September 1494, on the eve of the French entry into Florence. In him the New Learning attained its zenith, and his is also the higher praise of having revived his native Tuscan, which since Petrarch's day had fallen into neglect, of having at one stroke perfected the Italian epic stanza, and left to his successors a model of faultless style. That style, indeed, in all P.'s poetry is paramount to the subject-matter, and that he cared more about how than what he wrote is undeniable; but the fault belongs less to the poet than to the times in which he lived, when paganism and classicism had established artificial canons of sentiment and utterance, and Italian liberty lay crushed beneath a load of sloth, tyranny, and foreign wrong. The best edition of P.'s works is by Carducci (Flor. 1864). Mr. J. A. Symonds has translated portions of the *Orfeo*, *Giostra*, &c., in an article, *P.'s Italian Poetry*, in the *Fortnightly Review* for August 1873. See Mahly, *Angelus Politianus* (Leips. 1864).

Polk, James Knox, eleventh President of the United States of America, was born in Mecklenburg county, N. Carolina, 2d November 1795. The son of a respectable farmer, he received a good education, and after graduating at the University of Nashville in 1818, was admitted to the bar in 1820, and in 1824 elected member of Congress by the Democratic party. After holding several minor appointments, he was chosen Speaker of Congress in 1835 and 1837, and Governor of Tennessee in 1839. In December 1844 he was elected President of the United States with 170 votes as against 105 for Henry Clay. The chief events of his administration were the settlement of the Oregon boundary question, the reorganisation of the financial system, the Mexican war, and the acquisition of California and New Mexico. He died at Nashville, June 19, 1849. Though not possessed of great talent, P. was a man of firm character and irreproachable integrity.

Polka (Bohem. *půlka*, 'half'), a popular dance in three-quarters time, with the third quaver accented. It consists of three steps to

the first three beats of each bar, a rest being taken on the fourth beat. It originated in Bohemia about 1830, and on its introduction into England in 1843 had for a considerable time a reign of amazing popularity.

Pollack (*Merlangius pollachius*), a species of Teleostean fishes belonging to the *Gadidae* or cod family. It is common on the coasts of Britain, and is called the whiting and coal-fish. In Scotland its local name is the 'lythe.' The P. is caught in numbers by the rod and line, almost any white object, even a piece of rag, serving as a bait. It has three dorsal fins, the tail is forked, and the upper jaw is much shorter than the under.

Pollan (*Coregonus Pollan*), a fish belonging to the *Salmonidae*, found in certain fresh-water lakes of Ireland (e.g., Loch Neagh). It is allied to the Vendace (*C. Willoughbi*) of English lakes. Its average length is from 10 to 12 inches. The flesh is highly esteemed. The P. is caught in large numbers by nets. It appears to spawn in November and December.

Pollard (from *poll*, 'to cut off the head'; Low Ger. *bolle*, 'a tree-top'), a term which in the 17th c. denoted a tree lopped of its side branches, but is now applied to a tree whose crown or 'poll' has been cut off when at the height of 10 or 12 feet from the ground, that it may send out new branches near the section. Trees pollarded for fuel or fence-wood, are in England chiefly confined to hedgerows, or the banks of rivers running through marshy grounds; but on the Continent they are frequently met with in the open country, where their unsightly bareness does much to mar the landscape.

Pollen. See STAMEN.

Pollenza (*Valentia*), a town of Majorca, near the N. coast of the island, 30 miles N.W. of Palma, has a Jesuits' college, and produces coarse cotton and woollen cloths, boots and shoes, rope, &c. Pop. 7000. There are two small Italian towns of the same name, one 5½ miles from Macerata, near which Stilico gained his great victory over the Goths in 403 A.D., the other in the province of Cuneo, celebrated for its antiquities.

Pollilore, a town in the district of Chingleput, Madras Presidency, British India, near Conjeveram, and 43 miles S.W. from Madras. It is the scene of two battles. In 1780 Colonel Baillie was here completely defeated and taken prisoner by Hyder Ali. This was the greatest defeat the British had hitherto sustained in India. The lives of the prisoners were only saved by the intervention of Hyder's French officers. Paintings commemorative of the victory are still to be seen at Seringapatam. But in the following year, on the anniversary of the former battle according to the lunar calendar, Sir Eyre Coote won his first victory over Hyder Ali on the same spot.

Pollio, Caius Asinius, born at Rome in 76 B.C., first signalled himself by his accusation of the Pompeian tribune C. Cato (54), and having espoused the cause of Cæsar, and shared with him the passage of the Rubicon (49), was despatched to Sicily to aid in the expulsion of M. Cato, and thence to Africa, where he drew off the remnants of the Roman army after Curio's defeat by Juba. He next saw service at Pharsalia (48), as tribune of the plebs opposed Dolabella's measure for the cancelling of debts (47), attended Cæsar on his Spanish campaign (45), and at the time of the dictator's assassination (44) was carrying on the war against S. Pompeius with scant success, as administrator of the Further Province, which on the formation of the Second Triumvirate he exchanged for Transpadane Gaul. He played the part of peacemaker between Antony and Octavian in 40, was consul the same year, and in 39 earned a triumph by his victory over the Parthini in Illyria. Thenceforth he led a retired life, declining in 32 to avow himself a partisan of either Octavian or Antony, and dying at his Tusculan villa in 4 A.D. Himself no mean historian, orator, and playwright, if we accept the verdict of his contemporaries, P. is most famous as a liberal patron of letters in the persons of Virgil and Horace, as the founder of Rome's first public library, and as the originator of that mutual admiration system which afterwards formed a theme for the satire of Martial and Juvenal. Of his critical acumen, we know that he detected the 'Patavinity' of Livy, impugned the accuracy of Cæsar's *Commentaries*, and challenged Sallust for his pseudo-archaisms, a charge from which the critic's own perished

works were not entirely free (Quint. i. 8; ix. 4). See Thorbecke's *Commentatio de C. Assinii Pollionis Vita et Studis* (Lugd. Bat. 1820).

Pöllnitz, Karl Ludwig, Freiherr von, celebrated as a writer of memoirs, was the second son of Major-General Gerhard Bernhard von P., minister of state to the Elector of Brandenburg, and was born at Issomin, a village in the archbishopric of Köln, 25th February 1692. After squandering his patrimony, he travelled through various countries of Europe, bearing arms successively in Austria, Italy, and Spain, and nowhere fixing his abode, till at last King Friedrich II. of Germany took a liking for him, and made him his reader. In this position his disorderly habits often led him into disgrace, from which the force of his wit enabled him again to rise to the favour of Friedrich, who at length appointed him director of the theatre. After twice joining the Catholic Church, and as often returning to Protestantism, he became for the third time a Catholic, and died 23d June 1775. P.'s *Lettres et Mémoires, avec nouveaux Mémoires de sa Vie et la Relation de ses Premiers Voyages* (nominally Amsterd. 1735), and *Etat abrégé de Saxe sous la règne d'Auguste III., Roi de Pologne* (Frankf. 1734), widely read in his own day, are untrustworthy, witty, and scurrilous. After his death, Brunn published P.'s *Mémoires pour servir à l'Histoire des quatre derniers souverains de la Maison de Brandebourg, Rois de Prusse* (2 vols. Berl. 1792). P. is also the reputed author of *Histoire secrète de la Duchesse d'Hanovre, épouse de George I., Roi de la Grande Bretagne* (Lond. 1832), and editor of Gundling's posthumous *La Saxe Galante* (1737).

Poll'ock, Sir George, a son of David P., saddler to George III., was born in Westminster, 4th June 1786, and educated at a school in Vauxhall. He entered the Military Academy of Woolwich (1801), sailed for Calcutta (1803), and received his commission as lieutenant of artillery in the service of the East India Company (1804). He was present at the storming of Deeg and the unsuccessful assault on Bhurtpore (1805), in the Nepaulese campaign commanded the artillery under General Wood (1817), and for his services as lieutenant-colonel in the war with Burmah received the Companionship of the Bath (1825). In the Afghan War of 1842, with a single battalion of infantry, one regiment of dragoons, and fourteen guns, he forced the Khyber Pass, defeated Akbar Khan, and by his occupation of Cabul effected the relief of Jellalabad, being rewarded for these splendid services by the thanks of Parliament, the Grand Cross of the Bath, and a life pension of £1000 from the East India Company. He was appointed envoy at the court of Oude (1843) and military member of the Supreme Council (1844), returned to England (1846), and took up his residence at Clayham, obtaining his promotion as lieutenant-general (1851) and general (1859), whilst holding the senior directorship of the Company (1854-56). He was created field-marshal (1870), Constable of the Tower (1871), and a baronet (1872), and dying at Walmer, 6th October 1872, was buried in Westminster Abbey. See C. R. Low's *Life and Correspondence of Sir George P.* (Lond. 1873).—**Sir Frederick P.**, elder brother of the preceding, was born in London, 23d September 1783, and passing from St. Paul's School to Trinity College, Cambridge (1802), was Senior Wrangler and Smith's Prizeman (1806), and obtained a college fellowship (1807). Called to the bar at the Middle Temple in the same year, he travelled the Northern Circuit, dividing its honours with Brougham, Scarlett, and Campbell, was made a King's Counsel (1827), and returned as Conservative member for Huntingdon (1831). Having served as Attorney-General in Peel's Ministries of 1834 and 1841, he was created Lord Chief Baron of the Exchequer (1844), on the resignation of which office in 1866 he received a baronetcy. He died 23d August 1870, leaving a son, **Sir Charles Edward P., Q.C.**, who was born 21st October 1823, is the author of various legal treatises, and in 1873 was created Baron of the Exchequer.

Pollockshaw's, a thriving municipal burgh in Renfrewshire, Scotland, in a valley at the confluence of the White Cart and the Auldhouse Burn, 2½ miles S. by W. of Glasgow, and 6 E. by S. of Paisley. It is a station on the Glasgow and Barrhead Railway, has some good churches and an excellent public library, which is to be extended, with the addition of a reading-room, through a legacy of £2000 received in 1877, aided by local sub-

scription. Under the Education Act of 1872, £5187 had been spent upon school-buildings at the close of 1877. P. is the seat of important industries in cotton-spinning, weaving, bleaching, and dyeing. It has also paper-works, potteries, and large engineering works. In the year 1855-56, the rental of P. was £9955; in 1877-78 it amounted to £24,483. Pop. (1871) 8921. Two miles distant is the village of Thornliebank, where are situated the most extensive calico-printing works in Scotland.

Poll'ok, Robert, a Scottish poet and minister, was born in 1799 at Muirhouse, in the parish of Eaglesham, Renfrewshire. After going through his Arts course in the University of Glasgow, he entered the Divinity Hall of the Secession Church, where he studied for five years under Dr. Dick, and was licensed to preach in 1827. In the same year he published, by the advice of Professor Wilson, the work by which he is known, *The Course of Time*, a poem in 10 books, intended to describe the spiritual life and destiny of man. The excess of work, however, consequent upon his carrying on the composition of his poem at the same time with his theological studies, brought on symptoms of consumption, and he removed to the S.W. of England along with his sister. He died at Shirley Common, near Southampton, 17th September 1827, just as he was beginning to find himself famous. His work has run through twenty-four editions, a success which is chiefly owing to its popularity among the religious classes of Scotland, of whose favourite Calvinistic doctrines the *Course of Time* may be considered a poetical embodiment. Formerly it was made the subject of much extravagant praise, the young author, whose premature death heightened the interest in his work, being often profanely compared to Milton. But although there are many passages which show a poetical gift of high promise, and one or two which even glow with a sublime ardour, the interest is ill-sustained, and the general effect of the whole production is extremely heavy and monotonous. The greater part is not superior to an ordinary Scotch sermon. Before publishing his poem, P. had written three prose tales, entitled *Helin of the Glen*, *Ralph Gemmell*, and *The Persecuted Family*, which have been frequently published in one volume under the title *Tales of the Covenanters*. See the Memoir of his life (1843).

Po'lo, a modern game devised by the British officers in India to take the place of football, for which the climate was unfavourable. It resembles hockey and golf, but the player is mounted on horseback, and wields a 'mallet,' which must be 4 feet 4 inches long. It is played by 'sides,' as in football; and the object is to drive the ball from one goal to another. Even when the player is a skilful rider, there is considerable danger in P., as much, however, from collisions and blows with the mallet as from falls. By the club rules, as played at Jerome Park, the height of the ponies used is limited to 14 hands. The animals are 'hog-maned,' and have their tails cut short. P. has rapidly become one of the most popular of all British games, and has also taken kindly to American soil since it was introduced by Mr. James Gordon Bennett in 1876. In the latter country Mexican mustangs are now trained for P.-playing.

Po'lo, Marco, of a patrician family of Venice, Dalmatian by extraction, was born in 1250. His father and uncle, Nicolo and Maffeo P., after sailing on a trading expedition to Constantinople, crossing the Black Sea to the Crimea, travelling overland to Bokhara, and passing some time in Cathay, returned laden with wealth after an absence of nineteen years. In 1271 they again set out, accompanied by Marco, then twenty-one years old. Bearing letters from Gregory X., they made their way into the interior of Asia, through Greater Armenia, Persian Irak, Khorassan, by the city of Balkh into the country of Badakhshan, at the source of the Oxus, where the illness of Marco detained them twelve months. Resuming their journey to the N.E., they crossed the high table-land of Pamir (a route followed again by no European till the journey of Lieutenant Wood to the sources of the Oxus in 1838), and proceeded to Cashgar, Yarkand, and Khotan, reaching the city of Lop or Kobi. Traversing for thirty days the desert of Gobi, they arrived at Shatchen in Tangut, whence they journeyed to the city of Karakorum. When they came within forty days' journey of Cambaluc (i.e., *Khan-baligh*, 'imperial city,' probably Pekin), capital of Cathay, an escort met them and conducted them to the imperial city. The Khan employed Marco about his person, and when

he had become acquainted with the language and customs of the Mongols, employed him in embassies to some of his chiefs. Marco everywhere made careful notes of all that came under his observation. As the Khan's representative he visited successively Western China, Eastern Thibet, and thence to the borders of Burmah (Mien). Though our information is only incidental, it would appear that he was later charged with a mission to India, and for three years acted as governor of the city of Yang-chu-fu. After having spent seventeen years in the Khan's service, the Polos with great difficulty obtained permission to visit their native country. They were joined by an embassy from Kublai to the King of Persia, and the whole party sailed from Fu-kien in 1292, in a fleet of fourteen ships. They touched at Ziambar, Borneo, Lobak, Sumatra, the Nicobar and Andaman Islands, Ceylon, and the Carnatic, and sailed up the Persian Gulf. Thence they travelled by land through Kurdistan and Mingrelia to Trebizond; and again taking ship on the Black Sea, they arrived at Venice in 1295. Dressed like Tartars, and speaking their native tongue with difficulty, they could scarcely gain recognition from their friends. Maffeo became one of the chief magistrates in Venice. Marco commanded a galley in the fleet sent (1298) against the Genoese, was wounded in an engagement, and was carried prisoner to Genoa. During his captivity he dictated an account of his travels to Rusticiano, a humble litterateur of Pisa. In 1299 Marco returned to Venice, where he married and had three daughters. He died in 1324. Nicolo, the father, was dead before August 1300; Maffeo, the uncle, was alive and well in 1309. The description M. P. gave of his travels was long discredited; even on his deathbed he was adjured to retract his supposed falsehoods. But he remained firm; and now his work remains to the geographical world a wonder of accurate information. He was the first to trace a route across the breadth of the Asiatic continent, naming and describing kingdom after kingdom from Cilicia to the Yellow Sea. He revealed China with its mighty rivers, swarming cities, and rich industries; described for the first time the strange nations on its borders—Thibet, Laos, Siam, Cochinchina, and Japan; and made known to Europe the wondrous Indian archipelago, India itself, not as a mythical region but as a real country, visited and partly explored, the secluded Christian kingdom of Abyssinia, and in remoter quarters the high plateau of Pamir, Siberia, and the Arctic Ocean.

It is a curious fact, only ascertained within the last half century, that the original MS. of the 'Book of M. P.' was in French, and very bad French. But most of the MSS. (of which eighty are known) are in Latin, after the version of Friar Pipino, executed in P.'s lifetime. The first printed edition appeared at Antwerp about 1485, and at Venice in 1496. The French and Latin texts were published in the *Mémoires* of the Paris Geographical Society in 1824. Marsden's English translation (1818), revised and annotated, forms a volume of Bohn's Antiquarian Library (1854). Pauthier's edition (Par. 1865) brought a vast amount of curious Chinese learning to bear on the subject; but the principal contribution to the literature of the subject is Colonel Yule's *Book of Ser M. P.*, a new translation (2 vols. Lond. 1875).

Polotsk, a town of Russia, in the government of Vitebsk, stands at the confluence of the Polota with the Dvina, 95 miles E.S.E. of Dünaburg by rail. It is the seat of a Greek-United archbishop; has a kremlin, several Greek and Catholic churches, and a cadet academy (formerly a famous Jesuit college); and carries on a lively river trade. Pop. (1871) 11,928. After passing from the Tartars to the Russians (1564), P. was captured by Stephen Bathori (1576), next became capital of a Polish *voivodship*, and finally reverted to Russia (1772).

Polta'va. See PULTAVA.

Polyand'ry (Gr. *polus*, 'many,' *aner*, *andros*, 'a man') is the custom prevailing in many wild tribes by which a woman is married to several men at once. The Todas of India, the people of Thibet, and other tribes of Asia, follow this practice. It exists also in Ceylon, in the Aleutian Islands, among the Koryaks, among the Zaporovian Cossacks, among the tribes of the Orinoco, and in Lanzarote, one of the Canary Islands. It appears that in ancient times the field of P. was wider than it is now. Cæsar mentions it as a practice of the Britons, and Tacitus, in spite of his well-known passage regarding the monogamy of the Germans, still affirms that in his time traces of the

P. existed among the Goths. The custom, like that of polygamy, originated in unequal balance of the sexes. See Humboldt's *Personal Narrative* (trans. 1819), Grey's *Polynesian Mythology* (1855), Latham's *Descriptive Ethnology* (1859), Tennent's *Ceylon* (1859), Lubbock's *Origin of Civilisation* (1870), and Taylor's *Primitive Culture* (1871).

Polyan'thus (Gr. 'many-flowered'). In the Primrose (q. v.) the pedicel of each flower appears to spring from the root, but the inflorescence is in reality a sessile umbel, and the flower stalks are not true *scapes* (see INFLORESCENCE). Sometimes it is found with a more or less peduncled umbel, and it is from such a form as this the P. has originated, so that it is merely a cultivated variety of *Primula vulgaris*, and its diversified appearance results from the skill of the horticulturist in selecting and propagating from the best 'sports.' The P. is not the same as the English oxlip, which is sometimes made a synonym of it, that being a series of hybrid forms between the primrose and the cowslip. The true oxlip is a well marked species, very rare in Britain.

Polyan'thus Narciss'us. See NARCISSUS.

Polyatom'ic Al'cohols include what are ordinarily called secondary and tertiary alcohols. A primary alcohol when oxidised loses hydrogen and yields its aldehyd ($C_2H_5O + O = C_2H_4O + OH_2$); a secondary alcohol similarly treated yields a ketone ($C_3H_7O + O = C_3H_6O + OH_2$); while a tertiary alcohol breaks up when oxidised into a mixture of acids. According to the accepted theory, these alcohols are thus distinguished. Methyl alcohol may be regarded as marsh gas having its one hydrogen atom replaced by hydroxyl (OH). By replacing another hydrogen atom by a hydrocarbon (CH_3, C_2H_5 , &c.), the higher homologues are obtained; and as long as this substitution is so affected as to leave two of the original marsh gas hydrogen atoms, the alcohol is a primary one. If only one of the marsh gas hydrogen atoms is left unaffected, a secondary alcohol is obtained; and when all have been replaced by various hydrocarbon radicles, a tertiary alcohol results. It is evident then that a secondary alcohol must contain not fewer than three carbon atoms, and a tertiary alcohol not fewer than four.

Polybas'ic Acids are acids possessing more than one hydrogen atom capable of being replaced by a metal equivalent.

Polyb'ius, a Greek statesman and historian, was born about 204 B.C. at Megalopolis in Arcadia. His father, Lycortas, the friend of Philopemen, became at his death in B.C. 182 general of the Achæan League. Educated by these men in war and politics, P. was a champion of national independence, siding neither with the Macedonian nor the Roman party in the Achæan League. On the breaking out of the war between the Romans and Perseus of Macedon, P. and his fellow-moderates, in opposition to Callicrates, the leader of the Roman party, sought to remain neutral, but in 169 the commissioners of the Senate, Popilius and Octavius, declared neutrality hostile, naming specially as unfavourable to Rome, Lycortas, Archon, and P. This crushed the national party, and in the same year Archon was made general, and P. commander of the horse, with orders, if needful, to help the Romans. Shortly after, by decree of the League, P. was sent to offer the whole Achæan force to the consul Q. Marcus Philippus in Macedonia. After the defeat of Perseus at Pydna (168) the Roman Commissioners C. Claudius and Cn. Dolabella ordered 1000 of the noblest Achæans, including P., to be carried off to Italy (167), on the charge of not having aided the Romans. P. lived at Rome with Atilius Paullus and his sons Fabius and Scipio till 151. Through Scipio he got that access to the state documents so necessary for his great work, attending him, too, in his military expeditions. In 151 the surviving Achæan exiles were permitted to return to Greece. There P. remained till 149, when he appears with the consul M. Manilius at Lilybæum. In 146 he witnessed the destruction of Carthage by Scipio, and returning to Greece shortly after the fall of Corinth, aided in obtaining moderate terms from the Romans, and in drawing up new laws for his vanquished countrymen, who raised statues to him at Megalopolis, Mantinea, Pallantium, Tegea, &c. From this time till his death by a fall from his horse in 122, P. was engaged on his history. He visited Egypt in 143, and was

probably with Scipio at the fall of Numantia in 134; in earlier life, too, he had journeyed in Africa, Spain, and Gaul. P. wrote five works. His *Life of Philopemen*, in three books, his treatise *On Tactics*, praised by Arrian and Ælian, that *On Living under the Equator*, mentioned by Strabo, and his *History of the Numantian War*, referred to by Cicero in a letter, have entirely perished. His great work, the *Universal History*, contained forty books. The first part (from 220 B.C., where Aratus stops, to 168), aiming to show how the Romans had in these fifty-three years subdued most of the world, contained the history of the second Punic War, the Social War in Greece, the war between Antiochus and Ptolemy Philopator in Asia, and the subjugation of Macedonia by Rome in 168. Books I. and II., however, narrate briefly the history of Rome from its capture by the Gauls (390 B.C.) to the beginning of the second Punic War (218 B.C.). The second part brought down the history to 146 B.C., when with the fall of Corinth Greece was completely subdued; Book XL. forming a chronological summary of the whole. The style of P. is by no means pure, is without ornament, and lacks care both in the choice of words and the construction of sentences. He was, moreover, utterly unimaginative, but his judgment was 'cool, calm, and calculating,' and his preparatory studies and practical knowledge of war and politics very great. Hence his work is thoroughly didactic, a 'Pragmateia,' as he calls it, rather than a history. Of the forty books we have five entire, and a number of fragments and extracts, some of considerable length—e.g., one from Book VI., giving an account of the Roman army, discovered at Corfu shortly after the revival of learning. The best annotated edition of P.'s works is that of Schweighäuser (8 vols. Leips. 1789-95, and Oxford, 5 vols. 1823); the best texts are Bekker's (Beil. 1844), and Hultsch's (4 vols. (1867-72). See Livy, XXVIII.-XLV., Plutarch, *Lives of Philopemen and Paulus Æmilius*, and K. W. Nitzsch, *Polybius* (Keil, 1842).

Poly'carp, one of the Apostolic Fathers (q. v.), was a bishop who suffered martyrdom at Smyrna soon after the middle of the 2d c. All our information regarding him is derived from two authorities—the writings of Irenæus (q. v.), and a letter from the Church at Smyrna to the Philomelians, giving an account of his martyrdom and the many miracles which accompanied it. According to a letter of Irenæus preserved in Eusebius, P. was instructed by the apostles, had intercourse with many who had seen Christ, and was appointed bishop for Asia in Smyrna, where, at an exceedingly old age, he departed this life. According to the same authority he sojourned at Rome in the time of Bishop Anicetus or of the Emperor M. A. Antoninus, and converted many heretics to the Church of God. Jerome (q. v.), paraphrasing and amplifying the account of Irenæus, tells us that P. was a disciple of the Apostle John, by whom he was ordained Bishop of Smyrna, and was chief of all Asia, inasmuch as he saw and had for masters some of the apostles and those who had seen the Lord. Again Jerome and Eusebius, interpreting the visit of P. to Rome in the light of the Pascal controversy, which, however, did not arise till after the time of P., gathered from the above passage of Irenæus that while Anicetus ruled the Church of the Romans, P., yet surviving, came to Rome and entered into a conversation with Anicetus on account of some discussion in reference to the day on which the Passover was to be held. According to the letter called the *Martyrium of P.*, which claims to have been written by eye-witnesses of the martyrdom and in the following year, but which from its contents—miraculous and non-miraculous—was probably the work of a much later period, P. was burned at Smyrna 'after he had served Christ eighty-six years.' Eusebius states that he suffered death under M. A. Antoninus, who began to reign 161, so that, however soon after that date his martyrdom be fixed, there is a difficulty, either about the great age of P. or his intercourse with the apostles. The date has been fixed by various writers at 147, 161, 166, 169, 175, 178; but all by mere conjecture. The only extant writing of P., although others are mentioned by later writings, is an Epistle to the Philippians, regarding the authenticity of which there is much controversy. The best editions are by Hefele (1839, 4th ed. 1855), Jacobson (1838, 4th ed. 1866), and Dressel (1857, 3d ed. 1876). See Donaldson's *Christ. Lit. and Doctr.* (vol. i. Lond. 1864); Clementson's *Epistles of Ignatius and P.* (1827); and an Essay by Canon Lightfoot in the *Contemporary Review* (May 1875).

Pol'yochrome Printing denotes the art of printing two or more colours at a single operation of the press. Of the several processes from time to time devised, that patented in 1820 by Sir William Congreve, and since then modified and improved, has been most successful. Congreve employed compound metal plates so constructed as to separate and descend to different levels, at which the coloured inks were severally applied, and afterwards to rise and unite to form a single printing surface. Recently a polychrome process on an entirely different plan from the above, by which any number of colours forming pictorial designs may be printed simultaneously, has been patented in this country by C. O. Radde of Hamburg. See STENOCHROMY.

Polycotylédonous Plants. In the same way that plants with no cotyledons are called *acotyledonous*, those with one *monocotyledonous*, and those with two *dicotyledonous*, the name P. P. has been given to the comparatively small number having from two to many cotyledons. This occurs in *Conifera*, especially in the genera embracing the fir, spruce, and larch, in which up to fifteen have been observed. Some botanists, however, consider that such plants have normally two cotyledons, which have been merely deeply divided into a number of linear segments.

Poly'crates, son of Æacus, in the 6th c. B.C. made himself tyrant of Samos, and having raised a fleet of one hundred vessels, subdued Lesbos, Miletus, and other neighbouring states. So great and unbroken was his prosperity, that Amasis (q. v.), his friend and ally, counselled him to sacrifice his dearest treasure, thereby to avert the jealousy of heaven; and P. cast into the sea a costly signet-ring, only to recover it a day later from the belly of a fish, as Schuller sings in his *Ring des Polykrates*. Thereupon Amasis, so runs the story, broke off his alliance with one whose fortune seemed too good to last; though Grote considers it more probable that it was P. himself who abandoned his Egyptian for a Persian ally, as in 525 we find him aiding Cambyses (q. v.) in his invasion of Egypt with forty vessels manned by discontented Samians, who were to be set in the forefront of the fight. They escaped, however, their intended fate, and returning with a mixed Spartan and Corinthian force, besieged P. for forty days within his citadel. His hour was not yet come, and for three years longer he ruled with increased magnificence, till in 522 his deadly enemy Orontes, satrap of Sardis, lured him to the mainland, and there had him seized and crucified.

Polycystina, a group of *Protozoa*, belonging to the class *Rhizopoda* (q. v.), and allied to the *Foraminifera* (q. v.). These animals are all microscopic, and possess shells of flinty material, and of exceeding delicacy of form and beauty of outline. They are usually included in the group *Radiaria*. Many species occur in a fossil state, the so-called 'Infusorial earth' of Barbadoes being almost entirely composed of the minute shells of P. This deposit is of Tertiary age.

Polydip'sia (Gr. 'great thirst') is a term which has been applied to the disease *Diabetes Insipidus* (q. v.).

Polygala'ceæ is a natural order of herbs or shrubs with alternate or sub-opposite leaves; small or showy irregular flowers, either solitary or racemose, having their two inner sepals petaloid; petals, three or five; ovary free, two-celled; style simple. There are about 400 species distributed through tropical and temperate regions. The properties may be summarised as bitter, emetic, purgative, and diuretic. *Polygala* is the type genus, and out of its 200 species is represented in Britain by three, to which the name 'milkwort' is given. *P. vulgaris* is a pretty plant, with white, pink, blue, lilac, or purple flowers, and in some of its varieties is common on heaths, poor pasture-ground, &c.; *P. calcaria* is confined to the chalk-hills of S. England; and *P. austriaca* is very rare and local. Many of the species possess medicinal properties, but the only one that has passed into notoriety is *P. Senega*, the root of which, under the name of Senega Root, has its place in *materia medica* as 'an excellent stimulating expectorant, well adapted for chronic bronchitis in old people, and for the advanced stages of pneumonia.' It is a N. American species, and was first introduced into medical practice as a remedy for snake-bites. Of Cape species, several are in cultivation, such as *P. oppositifolia*, *P. latifolia*, *P. cordifolia*, their purple petaloid sepals and fringed keel-like petal rendering them elegant and attractive ornamental.

plants. *Comesperma volubilis*, a graceful little twining plant of Australasia, bearing a great abundance of beautiful blue flowers, belongs to the same category. *P. Chamæbuxus*, a shrubby European species, is frequent in gardens. The S. American species of *Securidaca* ramble to a great height over forest trees, and when in flower make a handsome show. To this genus belongs the 'Buaze' (*S. longipedunculata*) of Livingstone's 'Travels,' the fibre of which resembles flax, and from its high quality will probably, on the opening up of Africa, be an article of commerce. *Munditia spinosa* of S. Africa yields an insignificant edible fruit. The anomalous genus *Krumaria* is now included in *P.*, and will be referred to under RATTANY ROOT.

Polygambus (Gr. *polys*, 'many,' and *gamē*, 'marriage') is applied in botany to those species of Phanerogamia (q. v.) that bear on the same plant some flowers entirely male, others entirely female, and others hermaphrodite. Examples of such are the elm, maple, and horse-chestnut.

Polygamy (Gr. *polys*, 'many,' and *gamē*, 'marriage') is a name for the custom according to which a man may lawfully have more than one wife at a time. In Asia *P.* has existed from time immemorial, and Mohammedanism has fostered the practice. Montesquieu surmised that the custom arose in consequence of the great proportion of females in the population of the East; it more probably owed its origin in part to the premature old age of women in certain countries. In the Scriptures *P.* is mentioned as existing before the flood; in patriarchal times it was common; the Mosaic law tolerated it. There is no indication that it was practised by the Jews in the time of Christ. The Koran allows a man to have four legitimate wives; but only the rich can indulge so far. Arabs generally content themselves with one wife. *P.* can never prevail except where slavery exists in some form or other, its expense otherwise being too great.

A statute of Edward I. places *P.* among the capital crimes. By statute of George III. it is made punishable with imprisonment or transportation for seven years. By the laws of ancient and modern Sweden its penalty is death. In modern times *P.* has had defenders. Bernardus Ochmus, in the 16th c., published *Dialogues* in favour of *P.*, which were replied to by Bera. John Iyser, a Lutheran divine, took a firmer stand in *Polygamia Triumphatrix* (Lond. 1692). The Rev. M. Maun also advocated *P.* in *Thelyphthora*, a work in which he maintained that St. Paul's injunction that a bishop should be the husband of one wife implied that other men might have more wives if they chose. The development of *P.* by the revelations of Joseph Smith, the Mormon prophet, in 1843, needs only to be mentioned.

Polygar (*palegara*, 'tent-man'), the name applied to a class of petty chieftains, who were found by the British at the close of the last century established in the S. of India, especially in the Carnatic. They occupied hill forts, and lived by plunder. They offered a strenuous opposition to the pacification of the country; but the majority were dispossessed, and the remainder, deprived of their independence, have settled down into ordinary *semdars* or landholders.

Polygastrica (Gr. 'many-stomached'), a term applied by Ehrenberg to denote the group of Infusorian animalcules and other organisms with which they were at first associated. The name *P.* was bestowed on these organisms under a misapprehension of their structure, no stomach or digestive apparatus being developed in the Infusoria.

Polyglot (Gr. *polys*, 'many,' and *glossa*, 'language') is a term properly applicable to any book containing the same subject-matter in various languages, but is now almost solely applied to editions of the Bible in which the original text and several of the ancient or modern versions of it are arranged alongside of one another, so that any one portion of the text and the corresponding portions of the versions are exhibited at one view. The idea of a *P. Bible* was first carried out as early as the 3d c. by Origen in his *Hexapla* (q. v.). About the beginning of the 16th c. the famous printer Aldus Manutius formed the plan of a *P.*, and printed a specimen page containing the first fifteen verses of Genesis in parallel columns of Hebrew, Greek, and Latin. His undertaking did not meet, however, with support, for no more of the work was printed. The only copy of this page known to exist is in the National Library of Paris (MSS. No. MMLXIV.). *P. Bibles* are generally divided into

greater and lesser. The former class includes four works—1. The 'Complutensian *P.*' (Compluti, 1514-17, 6 vols. fol.), so called from having been published at the Spanish town Alcalá, the Latin name of which is Complutum. It was produced through the exertions and at the expense of Cardinal Francisco Ximenes de Cisneros, Archbishop of Toledo, whose name appears on the title-page, and whom it cost over 50,000 ducats. The first four volumes contain the Old Testament, the Hebrew, Greek, and Latin being printed in three parallel columns, and the Chaldee paraphrase with a Latin translation at the foot of the page, while the margin exhibits the Hebrew and Chaldee radicals. The fifth volume includes the New Testament in Greek, with a parallel column containing the Vulgate Latin version, besides various prolegomena and appendices. The sixth volume contains a Hebrew and Chaldee lexicon to the Old Testament, an index of Latin words occurring in the work, an alphabetical list of all proper names in the Bible with their interpretation, and an introduction to the Hebrew grammar. Many MSS. were collated for this *P.*, but modern investigation has shown these to have been late and valueless. 2. The 'Antwerp *P.*' (Antverpiæ, 1569-72, 8 vols. fol.). This work, sometimes called the 'Royal *P.*' from its having been produced at the expense of Philip II. of Spain, was edited by Benedict Arias Montanus, a Spanish scholar, sent to Antwerp by the King for this purpose, and printed by Christophe Plantin, who was its original projector. The first four volumes contain the Old Testament in the Hebrew text (which is that of the Complutensian revised with one of Bomberg's Bibles), the Chaldee paraphrase, the LXX., and the Vulgate. The fifth volume comprises the New Testament in Greek, Latin, and Syriac; while the remaining three volumes are filled with lexicons and grammars of the various languages employed, together with indexes, a treatise on sacred antiquities, and (in the eighth vol.) a Latin translation of the entire Bible by Santes Pagninus, revised by Montanus. This *P.* is of great rarity, 500 copies only having been printed, and the greater part of these lost in a storm at sea with the vessel which was conveying them to Spain. 3. The 'Paris *P.*' (Lutetie Parisiorum, 1645, 9 parts in 10 vols. large fol.). This work was executed at the expense of the parliamentary advocate Guy Michel le Jay, who was reduced from great wealth to utter poverty by the undertaking. The first five volumes contain the Old and New Testament reprinted from the Antwerp *P.* The remaining four are devoted to the Syriac and Arabic versions of the Old Testament, with Latin translations of them; the sixth also including the Samaritan Pentateuch, now printed for the first time. As regards appearance and typography, this is unquestionably the most magnificent *P.* ever printed; but the incorrectness of the text, the absence of critical and other apparatus, as well as inconvenience of form and arrangement, make it of much less value than—4. The 'London *P.*' (Londini, 1657, 6 vols. fol.), which, edited by Brian Walton, and hence sometimes called 'Walton's *P.*,' surpasses all the others alike in point of correctness and fulness. Nine languages are employed, though no book is printed in more than eight. The first volume, besides prolegomena embracing sixteen separate dissertations, contains the Pentateuch, every sheet exhibiting at one view the Hebrew text, the LXX., the Vulgate, the Chaldee Targum of Onkelos, the Hebræo-Samaritan text, and the Samaritan, Syriac, and Arabic versions. To each of these, except the Vulgate, is annexed a literal Latin translation. The second and third volumes include the rest of the Old Testament in the same languages, except the Samaritan, and with the addition of an Ethiopic version of the Psalms. The fourth contains the Apocrypha in Greek, Latin, Syriac, and Arabic, with a twofold Hebrew text of the Book of Tobit. After these come two additional Chaldee Targums to the Pentateuch, and a Persian version of it, each having a Latin translation affixed. The fifth volume embraces the New Testament in Greek, Syriac, Latin, Arabic, and Ethiopic, with the addition of a Persian version in the case of the Gospels. The sixth volume forms an appendix to the work, containing a copious collection of various readings, besides various useful and learned dissertations. As a supplement to this work, Edmund Castle prepared his famous *Heptaglott Lexicon* (Londini, 1669, 2 vols. fol.). The lesser polyglots include (1) 'Vatablus's Bible' (1586, 3 vols. fol.), in Hebrew, Greek, and Latin, with preface, &c.; (2) 'Wolder's *P.*' (Hamburgi, 1596, 2 vols. fol.), in Greek, Latin, and German; (3) 'Hutter's *P.*' (Noribergæ, 1599, fol.). The plan of this work

is peculiar. The Old Testament portion, which is incomplete, extending only to Ruth, is printed in nine different languages, distributed through four different volumes in such a way that all the volumes include the Hebrew, Chaldee, Greek, Latin, and German, while each has in addition one of these modern versions, French, Italian, Saxon, or Slavic. The New Testament (2 vols. fol.) is in twelve languages, embracing, in addition to the above, except the Chaldee, Saxon, and Slavic, the Syriac, Spanish, English, Danish, Bohemian, and Polish versions; (4) 'Reineccius's P.' (Lipsix, 1750, 3 vols. fol.), containing the Old Testament in Hebrew, Greek, Latin, and German, the Apocrypha in the three latter, and the New Testament in Greek, Latin, Syriac, and German. It is very correctly printed, and includes useful appendices; (5) 'Bagster's P.', containing the Old Testament in Hebrew, Greek, Latin, English, German, French, Italian, and Spanish, and the New in these and also in Syriac; (6) Stier and Theile's *Polyglotten Bibel zum praktischen Hand-Gebrauch*, containing the Old Testament in Hebrew, Greek, Latin, and German, and the New in the three latter, the fourth column being filled with a valuable collection of various readings from other German translations. There are also polyglots of various portions of the Bible, the Psalms and the New Testament being those most frequently met with in this form. See Le Long, *Bibliotheca Sacra* (vol. i.); Dibdin's *Introduction*; Horne's *Manual of Sacred Bibliography*; Pettigrew's *Bibliotheca Susexiana* (vol. i. part 2); Butler's *Horæ Biblicæ*; and Adam Clark's *Succession of Sacred Literature*.

Polygnotus, the first great painter of Greece, was a native of the island of Thasos, but removed in 463 B.C. to Athens, which thereafter became the capital of the arts. To the genus of P., who may be regarded as the founder of historic painting, the highest tribute is paid by Aristotle, Lucian, Pliny, and others. He was the painter of the earliest authenticated portrait—that of Elpinice, the sister of Cimon; but his most important works, which adorned the public hall at Delphi, were the 'Destruction of Troy' and the 'Visit of Ulysses to Hades.' P. was surnamed *Ethographos* ('painter of character') by Aristotle; he created painting as an independent art, and, in the opinion of Warnum, 'for originality and discernment he has perhaps never been equalled by any artist, ancient or modern.'

Polygon (Gr. *polys*, 'many,' and *gōnia*, 'a corner'), in mathematics, is any figure plane or gauche bounded by straight lines meeting at definite angles. There are as many angles as sides; and when both the angles and the sides are all equal, and the figure confined to one plane, the P. is regular.

Polygonaceæ, or **Polygoneæ**, a natural order of dicotyledonous herbs, shrubs, or rarely trees, with alternate simple leaves, having usually sheathing stipules; the flowers are small, hermaphrodite, or unisexual; the perianth herbaceous or coloured; the ovary free, ovoid, trigonous, or compressed; the fruit, a one-seeded nut, generally enveloped in the perianth. It numbers about 500 species, of which the bulk are found in temperate regions. The characteristics are astringency, arising from the presence of tannin, and acidity, depending chiefly on oxalic acid; some are purgative and some acid. Of the type genus *Polygonum*, the sub-genus *Fagopyrum* has already been referred to under BUCKWHEAT, and *P. bistorta* under BISTORT. Other species are *P. convolvulus*, a strangling troublesome pest among crops; *P. persicaria* and its allies, ranking as prolific agrarian weeds; *P. aviculare*, or 'knot-grass,' an abundant and variable weed on waste and cultivated ground; *P. hydropiper*, called 'water pepper,' from its acrid properties, common in watery places; and *P. amphibium*, which as an aquatic is a handsome plant. These are all British species, and there are several others of interest to the botanist only. In the Himalaya, *P. cymosum* is used as spinach, and *P. sibboldii* supplies a good cattle fodder in Japan. *Rumex* contains about fifty species, a number of which come under the popular designation of docks (see DOCK). Some of these, as *R. obtusifolius* and *R. crispus*, are great nuisances to agriculturists. For other species see article SORREL, closely related to which group is *Oxyria reniformis* of the Arctic region and the Alps of the north temperate zone, forming an excellent pot-herb and antiscorbutic. It grows up to 4000 feet in the Scotch Highlands. The most important genus, both in an economical and medicinal view, is *Rheum*, for which see RHUBARB. The N. American genus *Eriogonum* is distinguished by the

absence of leaf stipules. Besides the species mentioned under *Calligonum*, in arid tracts of N.W. India, *C. polygonoides* locally constitutes half the larger vegetation, and in the S. Punjab the abortive flowers, which fall in great numbers, are swept up and made into bread. When in full bloom its small pink blossoms fill the air with a pleasant odour like over-ripe strawberries. Of *Atraphaxis*, an Asian and Cape of Good Hope genus, a few species are in cultivation, but present minor attractions. Of the few trees that belong to the order, *Coccoloba uvifera* is the most noteworthy, for which see SEA-GRATE.

Polyhymnia, or **Polymnia** (Gr. 'rich in song'), in Greek mythology, one of the Nine Muses (q. v.), the inventress of the lyre and the mother of Orpheus. In works of art she is represented in a thoughtful attitude, with the forefinger of her right hand placed upon her mouth.

Polymerism, in chemistry, is that kind of isomerism in which the substances, though they have the same percentage composition, have different molecular weights. Thus oxygen and ozone, whose molecular symbols are O₂ and O₃ respectively, may be looked upon as polymeric. The most interesting group of polymeric bodies are the hydrocarbons of the olefine series, ethylene (C₂H₄), propylene (C₃H₆), butylene (C₄H₈), amylene (C₅H₁₀), &c., and these being at the same time homologous, show a regular gradation in their boiling-points and specific gravities.

Polyne'sia (Gr. *polys*, 'much or many,' and *nēsos*, 'an island'), a geographical term of varied significance applied to the island regions of the central Pacific Ocean. Literally interpreted, the name would include all the groups from Sumatra to the Galapagos, together with Australia; and to this vast region the term Oceania has been applied by French geographers. It is more usual at the present time, however, to exclude from P. the Indian Archipelago—which has been called Malaysia—together with Australia, New Guinea, and the other islands S. of the Equator as far as the meridian of 180°. To this latter region have been given the names of Australasia and (New Zealand being excepted) Melanesia (q. v.). The remaining islands, after making these deductions, are broadly known as P., and it is of them that this article will treat. P. thus circumscribed is still a most extensive region, reaching from 20° N. lat. to 30° S. lat., and from the Pelew Islands in 130° E. long. to Easter Island in 109° W. long. The principal island groups comprised within it are:—N. of the Equator—the Ladrone, Caroline, Marshall, and Sandwich Islands: upon the Equator—the Gilbert and Galapagos Islands; and S. of the Equator—the Ellice, Phoenix, Samoan, Friendly, Society, and Marquesas Islands, with the Paumotu, or Low Archipelago. The general name of Micronesia (i.e., 'region of small islands') has been given to the islands N. of the Equator, with the exception of the Sandwich Islands.

The islands composing P. may be broadly divided into two kinds, viz., those of volcanic origin and those of coral formation. The former are for the most part rugged and mountainous, with sharp lofty peaks, the highest of which is the volcano of Mauna Kēa, in Hawaii, 13,953 feet above the sea-level. Besides the Sandwich Islands, the chief volcanic groups are the Ladrone, Marquesas, Society Islands, and Samoa. The shores of these islands are usually abrupt, and on account of the depth of the water, coral reefs are comparatively scarce. Active volcanoes are now found only in the Ladrone, Sandwich, and Kermadec Islands. The islands of coral formation are small and low, and much more numerous than the high or volcanic islands. For an account of their origin and different forms, see CORALS AND CORAL ISLANDS.

The climate of P. is tropical, but is tempered by the insular character of the land and by the influence of the trade-winds. In some parts hurricanes occur during two months of the year, but as a rule the climate is balmy and pleasant, and excessive heat is characteristic chiefly of the more bare and exposed of the coral islands. The soil, especially of the volcanic islands, is very fertile, producing the cocoa-nut, bread-fruit, banana, yam, and sweet potato in abundance. The cultivation of cotton, sugar, coffee, tobacco, rice, &c., has been commenced in some of the more civilised groups, and has entirely succeeded where the requisite labour is obtainable. Pigs, dogs, and rats, were the only quadrupeds indigenous to P., but cattle, horses, goats, and sheep have been successfully acclimatised, especially in the

larger islands. Birds and insects are numerous, but snakes are confined to certain groups. Fish are very abundant, and constitute the staple food of the inhabitants. The Bêche-de-Mer (q. v.) is plentiful on the reefs around many of the islands.

The inhabitants of the widely-scattered islands of P. are generally believed to belong to a single race, and they speak the same language with variations of dialect only. The origin of this race has been the subject of much interesting speculation and inquiry, and the question cannot yet be regarded as settled. The principal theories regarding the Polynesian race are four in number, viz. :—(1) That it is of American origin; (2) that it is of Malay origin; (3) that it is the result of an emigration of Turanian Mongols from Central Asia prior to the emigration of the Malays; (4) that it forms of itself a race distinct from any either in Asia or America, and independent of those continents. Of these various theories, the first is now generally abandoned, and the third has not advanced beyond the stage of hypothesis. The second has received the most extensive adoption, but the latest researches seem to point to the fourth being, after all, the true theory. The complexion of the Polynesians is brown, with a yellowish tinge, and their hair is black, long, and straight. They are tall and finely proportioned, with handsome features, the nose being not unfrequently aquiline, though, as a rule, the nostrils are rather wide. Throughout P. the chiefs are remarkable as presenting points of physical superiority to the bulk of the people, and this has led to a theory that the former belong to a different race of more recent appearance in P. The Polynesians are more athletic than the Malays, from whom they also differ, as Mr. A. R. Wallace has pointed out, in being 'energetic, demonstrative, joyous, and laughter-loving.' They are like the Malays, however, in their fondness for voyaging—a trait which has played a most important part in their history. The Polynesian language is simple and euphonic, abounding in vowels. Much has been made of the occurrence in it of certain Malay words, but this element is now generally recognised to be, as Mr. Wallace says, 'a recent phenomenon, originating in the roaming habits of the chief Malay tribes.'

Another question has arisen as to whether the Polynesian and Papuan races are radically distinct, or are simply variations of the same race. In disposition and habits the Polynesians and Papuans possess many points of resemblance, but in colour, hair, and language the differences between them are as great. The Papuans, moreover, do not possess the system of *tapu*, or taboo, and the habit of kava-drinking, both of which prevail throughout P. Their traditions are also entirely different, as well as their mode of warfare, the bow being in use among the Papuans, while the only weapons of the Polynesians were clubs, spears, and daggers. At the present day the Papuans and Polynesians do not appear to coalesce when resident on the same islands. The inhabitants of Micronesia differ in some respects from those of the rest of P., and approximate more closely to the Malays. In regard to the myths of P., Fornander says, 'The Polynesian and Hebrew and Chaldean legends' are not copies one from the other, but 'independent and original versions of a once common legend held alike by Cushite, Semite, Turanian, and Arian up to a certain time in their national life.'

When first visited by Europeans, the Polynesians were addicted to idolatry and various savage practices, such as cannibalism, infanticide, &c., but the labours of missionaries and the spread of civilisation have to a large extent put an end to these evils. Immorality is the great vice of the people, and to it and their fondness for ardent spirits is due the fact that in most of the groups the population is decreasing. Elephantiasis is the most common disease; but measles, influenza, and smallpox have at times committed great ravages. The Polynesian being lazy, and the prodigality of nature freeing him from the necessity of working for his living, the resources of the islands are still undeveloped, but by the employment of Chinese labourers they might be made to yield all kinds of tropical produce in abundance. See *An Account of the Polynesian Race: its Origin and Migrations, and the Ancient History of the Hawaiian People*, by Abraham Fornander (vol. i. Lond. 1878). Through the influence of Professor Max Müller, an annual grant was procured from the Earl of Carnarvon towards the printing of Whitmee's Comparative Polynesian Dictionary in January 1878.

Polyphe'mus, the name of a beetle (*Chelorchina polyphemus*) belonging to the family *Dynastidae*, and which attains a consider-

able size. The term is also given to a genus of crustaceans allied to the familiar 'water-fleas.' *P. pediculus* is a well-known species, occurring in ditches and ponds. These animals have only one eye—hence their name—and swim on their backs by means of the legs and antennæ.

Polyphe'mus (Gr. 'the much-speaking one'), the one-eyed Cyclops, a son of Poseidon and the nymph Thoosa, who in his Sicilian cave devoured six of the comrades of Ulysses. But that hero, first making the monster drunk, blinded him with a burning pole, and then escaped by concealing himself and his companions beneath the bellies of the giant's sheep, just as Sinbad does in the *Thousand and One Nights*. Ovid makes P. murder Acis, his rival in the love of Galatea.

Polyph'ony (Gr. *polys*, 'many'; *phōne*, 'voice'), in Music, a contrapuntal composition in which each part of a musical piece forms a melody in itself. In *Homophony*, on the other hand, the harmony is produced by a series of chords. See COUNTER-POINT. The following is a specimen of polyphonic composition:—

Pol'ypi, a term formerly used in zoology to denote all lower animals which had a circle of arms or tentacles surrounding the mouth, as well as other forms which did not exhibit such. The name 'polype' in former years was in fact used to describe any animal belonging to the Zoophyte group, or to the class represented by the sea-anemones, corals, and their neighbours; even the *Polyzoa*, a class widely removed from the preceding, were included under this term. In modern zoology its use is restricted to denote the members of the class *Actinozoa*. The term P. has no significance whatever in natural history classification; the division of animals corresponding most closely with the old group of the P. being the sub-kingdom *Cœlenterata* (q. v.), which includes the Zoophytes, Sea-anemones, &c. The *Polyzoa* (q. v.), on the contrary, are much higher animals—although presenting a striking resemblance to many of the *Cœlenterata*—and are included in the sub-kingdom *Mollusca* (q. v.).

Regarding the Zoophytes or *Hydrozoa*, as most nearly resembling one division of the old group of the 'P.' little need be said. They are as a rule compound organisms which agree in possessing one stomach-sac separated or specialised from the body cavity, whilst their reproductive organs are external processes of the body wall. Such organisms are well represented by the *Sertulariæ*, or 'Sea-firs,' which grow rooted and fixed to stones and shells, and which may be cast ashore in large quantities after storms. They present the appearance of plants, and reproduce their colonies by a suitable process of *budding* or *gemmation*, as well as by sexual processes. The separate individuals in the compound zoophyte are named *polypites*, each resembling in all essential details the little fresh-water polype or *Hydra* (q. v.) common in ponds and ditches. In the class *Actinozoa*, as already remarked, the animals receive the names of *Polypes*. They may be simple (e.g., sea-anemones) or compound (e.g., most corals, *Alcyonium* (q. v.), &c.). In this class a stomach-sac is developed, and the reproductive organs are internal. In both *Hydrozoa* and *Actinozoa*, the body substance consists of two layers—an outer or *ectoderm*, and an inner or *endoderm*; while the stinging or extricating organs termed *Cnide*, or 'thread-cells,' occur in all of these forms. The class *Hydrozoa* includes the following orders of zoophytes:—

1. *Hydrule*: ex. *Hydra*.
2. *Corynidae*: ex. *Tubularia*, *Eudendrium*, &c.
3. *Sertulariæ*: ex. *Sertularia*, *Plumularia*, &c.
4. *Campanulariæ*: ex. *Clytia*, &c.;

and, in addition, contains orders represented by such genus as the Portuguese men-of-war or *Physalia* (q. v.), the Jellyfishes or *Mouside* (q. v.), &c. In the class *Actinozoa* there are four orders:—(1.) *Zoantharia* (sea-anemones, reef-building corals, &c.); (2.) *Alcyonaria* (Alcyonaria, red coral, isis, &c.); (3.) *Rugosa* (extinct corals); and (4.) *Ctenophora* (q. v.) (Pleurobrachia (q. v.), Cestum, &c.).

Poly'pide, a name used in Zoology to indicate the separate individuals composing a *Polyzoön*, or member of the class *Polyzoa* (q. v.).

Polypod'ium is an extensive genus of ferns (*Filices*), distributed all over the world, but predominant in tropical countries. They have free veins, globose sori on the back of the frond, and no indusium; otherwise the species are much diversified in habit and appearance. The fronds are simple, lobed, pinnatifid, or compound; they present great contrasts in size, and vary in texture from membranous to leathery. In Britain *P.* is represented by the Polypody (*P. vulgare*), common on walks, banks, trees, &c.; the Oak-fern (*P. Dryopteris*) and the Beech-fern (*P. Phlegopteris*), both plants of shady places in hilly districts; and *P. alpestre*, limited to the Scotch Highlands. In addition there are two or three doubtful species. The genus numbers altogether about 400 species.

Polypodium vulgare.

Polyporus is an enormous genus of pore-bearing *Fungi*, of which two species are mentioned under Amadou (q. v.), and another forms Dry Rot (q. v.) in oak timber.

Polypri'on, a genus of Teleostean fishes represented by the Stone Basse (*P. cernium*), or Couch's P., and by other species. It is nearly allied to the perch, and is included in the family *Percide* itself. Its colour is a dark brown, tinted with purple. The first fin rays are soft. The Stone Basse usually swims near floating timber and wreckage, and appears to feed on smaller fishes.

Polyp'terus, a genus of Ganoid fishes inhabiting the Nile, Senegal, and other African rivers. The dorsal fin is separated into a number of small portions, each of which has a single spine in front. The pectoral fins consist of a central stem, to which the fin rays are attached. The tail-fin is *heterocercal*, or unequally lobed. The younger *P.* are said to have external gills in their young state; if this is true, they are related to the mud-fishes or *Lepisotirans* (q. v.), and also to the *Etiasmobranchii* (q. v.).

Poly'pus is an antiquated term employed to signify any pedunculated tumour attached to a surface, to which it was supposed to adhere like a parasite. The most common seat of *P.* is the mucous membrane, and the following are the principal varieties—(1) *fibro-cellular* tumours, developed in the sub-mucous tissue, and covered with mucous membrane; (2) tumours composed of *fibro-plastic* cells, not developed into fibro-cellular tissue; (3) *warty* and *epithelial* growths with narrow necks; (4) all sorts of tumours which project and have a narrow neck; (5) *hydatid P.*, consisting of a number of thin vesicles filled with a watery fluid. The varieties of *P.* are also named, according to their seat, *nasal P.*, *aural P.*, and *P.* of the *ratum* and *utero*.

Poly'stile (Gr. *polys*, 'many,' and *stylos*, 'a column'), in architecture, an edifice or court surrounded by several rows of columns.

Polytechnique. See ÉCOLE POLYTECHNIQUE.

Polyth'eism is the belief and worship of many gods. The prevalent view regarding *P.* is that it is a degradation of a previous Monotheism (q. v.), which is further identified with that of the Jews. This view was first attacked by Hume (*Essays*, 1742), who maintained that the mind gradually rises from a lower to a higher conception of Deity, and who has been followed by the more 'advanced' school of writers on religion since, although many able scholars still base their investigations on the older and what may be perhaps called the traditional view; e.g., Creuser (*Symbolik und Myth. d. a. Völker*), Schelling (*Religions-Philosophie*), Gladstone (*Studies on Homer and Juvenis Mundis*). According to the newer theory, *P.* is a

development of Fetichism (q. v.). Otherwise, religion is a development of Mythology (q. v.), the one beginning where the other stops; and if so, *P.* must necessarily precede Monotheism, because the elements of mythology are numerous, and therefore every religion must begin with a multitude of divine figures. Besides the above authorities, see T. Parker's *Discourse of Religion* (Works, Lond. 1866), Goldziher's *Mythology among the Hebrews* (Eng. trans. Lond. 1877).

Polyzo'a, a class of *Molluscoida*, or lower Mollusca, defined as consisting invariably of compound animals, which have a complete digestive system, and a nervous system consisting of a single nerve-mass only, a heart being absent. The upper part of the digestive system can be protruded from and retracted within the body-sac or cell, and the mouth is surrounded by a circle of ciliated tentacles. Of the *P.* no better examples can be cited than the *Flustra* or 'sea-mats' which are cast upon our shores, and which, growing rooted and attached to stones and shells, resemble pieces of pale brown seaweed. The *P.* inhabit fresh waters and the sea, and the name 'corallines' is not unfrequently applied to them, both in a recent and in a fossil state. Each *Polyzoön* consists of a colony of animals (or *polypides*), which has grown from a single polypide by a process of continuous budding. The single and primitive polypide in its turn was produced from an egg, developed by the generative organs possessed by each member of the colony. Each polypide is enclosed in a double-walled sac or cell, the outer wall being named the *ectocyst*, and the inner wall the *endocyst*. No connection exists between the various members of the colony, save such as may be maintained by the common integument that unites them. The so-called *colonial nervous system*, which was supposed to bind the members of the colony together, has been almost certainly proved to be non-existent. A mouth surrounded by tentacles, a stomach and intestine, which is bent on itself and terminates close to the mouth, comprise the digestive system, and present us with a superiority of structure to the Hydrozoa or zoophytes, with which the *P.* were long confused. The interior of the cell is filled with the nutritive fluid, which is circulated, in the absence of a heart, by the agency of the *cilia* lining the endocyst. The nervous system consists of a single nervous mass or *ganglion* placed on one side of the gullet. No sense-organs appear to be developed. On the exterior of the cells of *P.* certain curious little bodies named *Acicularia*, or 'bird's-head processes,' are found. These exhibit continual movements, but their exact nature and relations to the *P.* on which they exist are unknown. The muscular system of the *P.* is well developed, and consists of *retractors*, by means of which the animals are enabled to withdraw themselves into their cells, and of *parietal* or *circular* muscles. The *P.*, as already said, reproduce themselves by budding or gemmation, this process providing for the growth of each colony. But new colonies spring from eggs or ova, which are developed by the complete reproductive apparatus belonging to each cell, the *P.* being thus *hermaphrodite*. Certain peculiar bodies, supposed to be internal buds, and named *winter-eggs* or *strobilata*, also give origin to new colonies. The *P.* are divided into two groups—the *Phylactolemata* or *Hippocrepian P.*, in which the tentacles are arranged in a horse-shoe shape or crescentic fashion, and in which a valvular process or epistomie guards the mouth. Most of the fresh-water *P.* belong to this group. The second division is that of the *Gymnolemata*, in which no epistomie exists, and in which the tentacles are arranged in a circular fashion. To this latter group belong most of the marine *P.* Some of the best-known genera of *P.* are *Flustra*, *Eschara*, *Cellularia*, *Salicornaria*, *Bucellaria*, *Membranipora*, *Lepidaria*, *Frideruelia*, *Bowerbankia*, *Alcyonidium*, *Pedacellina*, *Cristatella*, &c.

Poma'ceæ, or **Pome'æ**, is a sub-order or tribe of *Rosaceæ* (q. v.), in which the tube of the calyx is more or less globose, lined with a fleshy and juicy disc, and the fruit a one to five-celled *Pome* (q. v.). It comprises numerous trees and shrubs common in temperate regions of the northern hemisphere, including a number that yield valuable edible fruits. For the most important members, see AMELANCHIER, APPLE, CRATÆGUS, COTONEASTER, HAWTHORN, LOQUAT, MEDLAR, PEAR, PYRALANTHA, QUINCE, SERVICE.

Pomade' and Poma'tum (Fr. *pommade*, from *pomme*, 'an apple'), terms originally applied to an ointment made of lard

and apples. It now denotes any aromatised fats, used principally for dressing the hair, and to a smaller extent for other toilet purposes. Plain pomades are made from purified animal fats, chiefly lard, aromatised in several ways, regarding which see *PERFUMERY*; but among the endless variety of preparations sold under fancy names by hairdressers, various oils, as almond, olive, palm, and specially castor oil, are used, the thickening and stiffening substances being white bees-wax and spermaceti. Beef marrow is also a favourite substance for preparing pomades, and in such as are put forward as hair preservatives and stimulants of the growth of the hair, tincture of cantharides is an almost invariable ingredient.

Pombal, Dom Sebastião José de Carvalho e Mello, Marquis of, was born in 1699 at Soura, near Coimbra. His youth was restless. He studied law at Coimbra, then entered the army for a short time, and having turned student again at Soura, eloped with a rich widow, Teresa da Moronha Almada. His uncle, Paulo Carvalho, obtained for him a post in England as secretary of legation in 1739; but in 1745 he was recalled, soon afterwards being sent to Vienna to settle a dispute between the Pope and Maria Theresa regarding the archbishopric of Aquileia. At Vienna, his first wife being dead, he married the Countess Daun. The queen-dowager of John V., conceiving an affection for his wife, recommended him to the notice of her son Joseph I. In 1750 he was appointed Foreign Secretary to this weak monarch, and he soon had him completely under control. He began reform by limiting the power of the Church, checked the Inquisition, resumed the corn lands, put an end to the flagrant abuses of power in the colonies, expelled the jesuit missionaries from Paraguay, and founded two trading companies, one for the E. Indies, another for Brazil. His administration did much to mitigate the distress occasioned by the great earthquake of November 1, 1755, which buried many thousands of persons. He was subsequently created Prime Minister, with the title of Count of Olyras. An attempt to assassinate the king on the night of September 3, 1758, only increased P.'s power, by placing the lives of the principal conspirators in his hands. The Duke of Aveiro and the Marquis of Tavôra were broken on the wheel, many of their accomplices being put to death with scarcely less cruelty. The Jesuits were suspected of slaying in the plot, and were decreed banishment. When they refused to go, P. caused them to be embarked in ships and transported to the States of the Church. Clement XIII. thereupon sent a nuncio to remonstrate, but the nuncio was sent home unheard. Clement XIV. shortly afterwards abolished the order of the Jesuits. In two wars with Spain P. had an opportunity of organising the army on a new basis, and put the frontiers in a better state of defence. He took great pains to raise the standard of education in Portugal. The university systems were overhauled: the study of physical sciences was introduced; navigation, shipbuilding, the principles of commerce and agriculture were taught by distinguished Englishmen and Frenchmen, and the censorship was relaxed. P.'s daring gained him renown and riches, but also many enemies. On the death of his master Joseph, in 1777, he was dismissed by the new king, Pedro III., and Portugal soon sank into the state of distraction from which he had raised it. He died at Pombal, 8th May 1782. See the *Vita de Seb. de Carvalho* (1781), an apology for P. entitled *Administration du Marquis de P.* (Amsterd. 1787), and Smith's *Memoirs of the Marquis of P.* (Lond. 1843).

Pome (Fr. *pomme*, Lat. *pomum*, 'an apple'). In the apple and its allies, parts of the flower besides the ovary unite to form the fruit—the edible portion being mainly developed from the calyx tube—and to this description of fruit the technical name P. has been assigned by botanists. In the specialisation of horticulture the word has been made use of to found the title of a journal called the *Pomologist*, also of the Pomological Society, established for the benefit of those who devote themselves more particularly to the cultivation of apples and pears.

Pomegranate is the name of a small tree called by botanists *Punica Granatum*—the only species of its genus, and, from its anomalous character, one of uncertain position in scientific classification. At present it is placed by our most experienced systematists in the natural order *Lythraceæ*. In habit, it somewhat resembles the hawthorn, and has often spinescent branches; oblong entire glabrous deciduous leaves; sessile terminal flowers, solitary or in three-flowered cymes, with usually scarlet petals

(sometimes yellow or white); and a pulpy fruit of about three inches in diameter, covered with a leathery rind. The structure of the fruit by its division into two tiers is remarkable, but of too technical a character to describe here. The P. is a native of N.W. India, Afghanistan, westwards to Syria, from whence at a very early period it was carried to Greece (where it is now run wild), to the N. African coast, and at a later date was transferred to other parts of the Mediterranean region. It is now grown in many subtropical countries of the Old and New Worlds, and by artificial means in less congenial latitudes. That it was a fruit highly prized we have the evidence of numerous ancient writers, in addition to the references to it in the Old Testament (e.g., Deut. viii. 8), in Homer's *Odyssey*, and the fact of its frequent sculpture on Egyptian monuments. The pulp has a sweet or subacid delicate flavour, is kept cool by the dense rind, and in warm countries proves particularly grateful and refreshing. The rind is extensively used for dyeing or tanning purposes, morocco leather being prepared from it or the bark. The flowers yield a light-red dye, the root is an excellent vermifuge (considered a specific against tapeworm in India), and the light-coloured wood is close-grained, hard, and heavy.

Medicinal Properties of P.—The dried bark of the root of the *Punica Granatum* is employed in medicine as an astringent and anthelmintic. It is considered to be more efficient than turpentine in the expulsion of tapeworm. A decoction of the fresh root (2 oz. to Oj) is preferred to that of the dried bark, and a pint of it should be taken in three doses, an hour apart, before breakfast. The dose of the pharmaceutical decoction is from 1 to 2 oz. As an anthelmintic, male fern is more relied on.

Pom'el, in Architecture, a knob, knot, or boss used as a final ornament on the top of the roof of a turret, the summit of a pavilion, &c.

Pommern (Lat. *Pomerania*, Slav. *po mor*, 'near the sea'), a province of Prussia, bounded N. by the Baltic, E. and S.E. by West Prussia, S. by Brandenburg, and W. by Mecklenburg. It extends along the Baltic for nearly 200 miles, with a breadth of 30 to 80 miles, and is divided into the three governmental districts of Stettin, Stralsund, and Koslin. P. is intersected by the Oder (q. v.), which, flowing through a marshy country, divides into many arms, of which Reglitz, the largest, forms the Danimer Lake, and falls, with the main stream, into the Frisches Haff. Other rivers are the Rega, Persauk, Grabow, Wipper, Stolpe, Lupow, Leba, and Rheda. The surface of P. is in general very level, and the coasts are defended by dykes. The soil is much less fertile than that of other provinces of Prussia, having only 6.6 per cent. of level loam and clay soil, while Prussia has, on an average, 28.2 per cent. In Koslin 45.4 per cent. of the soil is sand, and 35 per cent. mixed clay; in Stettin, 29 sand and 13 moor; in Stralsund, 20 sand and 63 mixed soils. The best part is, in spite of the sand dunes and marshes, the belt along the coast, of which the portion from Stolpe to Kolberg yields abundant wheat. The chief employment of the people is agriculture, and the principal productions are buckwheat, potatoes, flax, hemp, cabbages, beetroot, and tobacco. The rearing of horses, cattle, and sheep is the most important branch of industry, but there are considerable fisheries of salmon and sturgeon, eels, lampreys, and crayfish. P. is poor in minerals, but yields immense quantities of peat, besides bog-iron, lime, chalk, salt, and amber. P. had (1872) 364 miles of railway. It has a University at Greifswald, and 17 gymnasia, besides other schools. Area, 11,627 sq. miles. Pop. (1875) 1,462,290. P. formed part of the ancient kingdom of the Wends or Vandals. It was ruled by its own dukes from 1062, and converted to Christianity in the 12th c. by Bishop Otto of Bamberg. It attained its greatest extension under Duke Suanterpolk (1220-66), and the line came to an end with Boleslaus XIV. in 1637. Meanwhile part of the country had been occupied by the Swedes during the Thirty Years' War, and by the Peace of Westphalia

Pomegranate.

Sweden retained the island of Rugen and the rest of P., with the exception of Hinterpommern. The peace of Stockholm, in 1720, united all P. with Prussia, except the part N. of the Peene and the island of Rugen, which only fell to Prussia in 1815. See Barthold, *Geschichte von Rugen und P.* (5 vols. Hamb. 1839-45); Fock, *Rugensch-Pommersche Geschichten aus 7 Jahrh.* (6 vols. Leips. 1861-72).

Pomology. See POME.

Pomona (akin to Lat. *pomum*, 'apple'), the Latian goddess of fruit trees, at Rome had her special priest, the *Flamen Pomonalis*. Her husband, Vertumnus (Lat. *verto*, 'I turn'), the god of the changing seasons, had wooed her vainly under a thousand varying forms, but at last won her love, first as an aged crone, then as a blooming youth (Ovid, *Mét.* xiv. 623; Propert. iv. ii. 21).

Pomona, or Mainland, the largest of the Orkney Islands (q. v.), lying in the centre of the group, is 25 miles long by 15 broad, its coast-line being extremely irregular. Area, 150 sq. miles; pop. (1871) 16,541. From the W., where the cliffs rise steeply from the sea, the island has a general slope towards the E., the highest point being the Ward Hill of Orphir (876 feet). The surface, in great measure heath and moorland, is studded by numerous freshwater lochs, which, like their streams, abound in trout. Oats, barley, and turnips are the chief crops, and the herring fishery employs a large number of the inhabitants. Kirkwall (q. v.) and Stromness (pop. 1632) are the principal towns, and among the antiquities are the 'Picts' Houses' of Quanterness, the Maes-howe tumulus with its Danish runes, and the Standing Stones of Stennis, of which only sixteen out of sixty are still erect.

Pompadour, Jeanne Antoinette Poisson, Marquise de, mistress of Louis XV., was born in Paris, 29th December 1721. Her mother was the wife of Antoine Poisson, a clerk and army contractor; but P. was taken under the protection of one Normand de Tournehem, who, after educating her highly, gave her in marriage to his nephew D'Étoiles (9th March 1741). Her marriage gave her position and independence, but not contentment, for her mother had filled her mind with thoughts of becoming the king's mistress. She threw herself in his way at hunts in the most attractive costumes, and ogled him at masked balls, until (April 1774) she was established at court in the position she so much envied. Her success was deeply resented on account of her low birth, which, says Kitchen, 'seemed to be a far more heinous fault than her adultery.' At the period of her triumph she was in the height of physical grace, to which she added vivacity of mind and real kindness of heart. For the next twenty years France may be said to have been ruled by her. She kept her hold on Louis XV. by constantly devising new pleasures for his dull and jaded appetite. In order to keep him amused she had recourse to the services of the litterateurs and artists of the time, among them Voltaire, Crébillon, and Diderot. By and by she became the friend of financiers and ministers of state, and through her was exercised the patronage of all important posts. The sums of money which passed through her hands were immense, and the lands which were granted to herself and brother were of great extent. 'Yet,' says Lacretelle, 'she made a splendid, even a beneficent use of her wealth; she portioned poor girls, assisted old men, repaired ruined villages, followed the impulse of the new philosophy.' P. died 15th April 1764, having passed into the stage of *amie nécessaire* to the king, who remained perfectly unmoved when he lost her. She was buried in the Church of the Capucine, Place Vendôme, Paris. See Goncourt's *Les Maîtresses de Louis XV.*, Sismondi's *Histoire des Français* (vols. xxviii., xxix.). Everything really authentic regarding P. is to be found in M. Campardon's *Mde. de P. et la Cour de Louis XV.* (Par. 1867). In 1878 M. Malassis edited *Correspondance de Mde. de P.* It does not contain anything new, but the work is an *édition de luxe*.

Pompeii, a famous ruined city of Italy, situated near the S. base of Mount Vesuvius, about a mile from the Bay of Naples, and 15 miles S.E. of Naples by rail. In the excavation of P. we are presented with a picture, mutilated but not defaced, of actual life in a typical Roman city 1800 years ago. All the garniture at least of social and public life is here, for the city was stricken down, and 'the earth with faithful watch has hoarded all!' The tragic story of P. has been the theme of Schiller,

Bulwer Lytton, and other celebrated writers. P. is first mentioned in history in B.C. 310, but many of its monuments prove it to be much older. Founded by the Oscans, it was soon leavened with the civilisation of the Greeks, and its position near the mouth of the navigable Sarnus brought it prosperity. (Both the sea and the river were forced back from the town by the subsequent convulsions of nature.) After the Samnite wars P. was made subject to Rome, and the rebels in the Social War were defeated in the vicinity. Thoroughly Romanised in course of time, the town became a favourite retreat of the wealthier Romans (e.g., Cicero), and had at one time a pop. of about 30,000. In A.D. 49 an earthquake destroyed a great part of P., but it was shortly rebuilt in the improved style of imperial Rome. On the 24th August 79, P. was overtaken by the final catastrophe. First came a dense shower of ashes, covering the town to a depth of 3 feet, then a shower of red-hot rapilli or pumice-stones, 8 feet deep, followed at intervals by fresh showers of ashes. After the first shower many of the inhabitants escaped, but the whole number of those who perished is estimated at 2000. P. was ultimately found buried to a depth of about 20 feet, but this was partly the result of later eruptions. Extensive excavations were undoubtedly made in ancient times, and the ruins were freely ransacked for marbles and precious stones. But during the Middle Ages the very site passed out of the memory of man, and it was only the discovery of some statues and bronze utensils by a peasant in 1748 that drew the attention of Charles III. to the lost city. Excavations begun at this time were carried on feebly under the Bourbons, and with more vigour during the reign of Murat, but no regular plan was adopted till after the political changes of 1860, when the works were placed under the able superintendence of M. Fiorelli. Since then the chief movable objects found have been sent to the Naples Museum, while at P. itself a museum and library have been recently instituted, and a dwelling-house erected for students supported by Government. A railway has been constructed for the removal of *débris*, and at the present rate of progress Fiorelli calculates that P. will be completely excavated in seventy more years, at a cost of 5,000,000 francs. As much as 40,000 francs are received yearly as admission fees. The town walls, pierced by eight gates, are 2843 yards in circumference. The streets, bordered by pavements, are straight and narrow, the broadest being about 24 feet across. They are finely paved with large polygonal blocks of lava. In the streets are frequent notices, in red letters, referring generally to municipal elections. The chief peculiarity of the dwelling-houses is the internal court (*atrium*), surrounded by a covered passage, with the *impluvium*, or reservoir for rain-water, in the centre. P. is singularly rich in gay decorations. Marble is rare, and the columns even in the public buildings are made of tuff-stone or brick, but they are covered with stucco, and painted in almost glaring colours (red and yellow). The mural decorations are noted for extreme delicacy and variety. The Forum, with an open space of 515 by 107 feet, is paved with large slabs, and enclosed on three sides by an arcade, and on the fourth by the Temple of Jupiter, which was being restored at the time of the eruption. The Great Theatre, a very old building, was restored about the beginning of the Christian era, and could hold 5000 persons. To the S.E. is the amphitheatre, 148 yards by 114, which held 20,000 spectators. Between 1861-72 the skeletons of 87 human beings, 7 horses, and 3 dogs, were discovered. On 4th April 1878 were found, in presence of Prince Leopold, a gold armlet, a ring with engraved agate, two bronze vases, a cook's 'shape,' a blue glass vase, a terra-cotta lamp, &c. See Mazois' *Ruines de P.* (Par. 1812-38), Bieton's *Pompée* (Par. 1855), Gell's *Pompeiana* (1824, 39, new ed. 1876), Beule's *Drame du Vesuve* (Par. 1872), Helbig's *Campanische Wandmalerei* (1874), Prof. Overbeck's *P.* (3d ed. Leips. 1875); Fiorelli's *Scavi di Pompei* 1861-72 (1875).

Pompeius Magnus, Cneius, born 30th September 106 B.C., as the son of Pompeius Strabo, a noted soldier of fortune, was trained to arms in the Social and first Civil Wars. His father's death in 87 left him a seeming prey to his father's foes, but by marriage with a prætor's daughter he weathered the peril, and in 83 defeated three Marian generals and turned the scale in Sulla's favour, winning from him the title of *Imperator* and the hand of his step-daughter, for whom P. coldly divorced his first consort. In 81 he pursued the vanquished Marians to Africa, whence, after slaying Carbo and other heads of the faction,

together with four-fifths of a Numidian host, he returned in the same year to Rome to receive a triumph—a simple *equus*, not yet twenty-five—and be greeted with the enduring epithet of *Magnus*, 'the Great.' Having quelled the counter-revolution of the Consul Lepidus (77), he next advanced at the head of 30,000 men against Sertorius, who still upheld in Spain the Marian cause, and proved a worthier foe than any P. had yet encountered. Only after six chequered campaigns, and after Sertorius had fallen by the hand of his own legate and rival, Perpenna, could P. bring the war to a successful close (71), and hasten home in time to crush the rising of the gladiator Spartacus. Once more he entered Rome in triumph, and chosen colleague in the consulship to Crassus (70), proceeded to break with the aristocratic party by his measures for the restoration of the tribunate and extension of the judicial functions beyond the senate. The popularity thus earned gained him supreme command of a fleet and large force of infantry for the suppression of piracy in the Mediterranean, and this task accomplished in ninety days (67), he next obtained the conduct of the war with Mithridates. Him he defeated in Lesser Armenia (66), and within five years had established the Roman supremacy in Pontus, Phœnicia, Syria, and Palestine, taking Jerusalem after a three months' siege (63), and returning to Rome in 61 to celebrate his third and greatest triumph, when Romans learnt how P. had captured 800 ships, 1000 fortresses, and 900 towns, had founded 39 cities, enriched the treasury with 20,000 talents, and nearly doubled the republic's revenue. But meanwhile there had arisen one, his equal in arms and far his superior in statesmanship, Cæsar (q. v.), with whom and Crassus, to secure the ratification of his acts in Asia, P. found himself obliged to form the coalition known as the First Triumvirate (60). In vain did he henceforth seek to stem by jealous edicts that rival's career of conquest, and bind the people to himself by largesses of corn and the dedication of a splendid temple; in vain did he once more court the aristocracy, and in the year succeeding Crassus' death obtain the sole consulship (52). Cæsar's passage of the Rubicon (49) forced P. to fly to Greece, where, after a passing victory at Dyrrachium, he saw the host hastily mustered by the fame of his Eastern conquests melt at Pharsalia before the Cæsarian veterans. From that fatal field he rode to the coast of Thessaly and took ship for Egypt, where, as he stepped ashore, he was stabbed, at the bidding of the eunuch-regent Pothinus, by one of his old centurions, 20th September 48 B.C. P.'s military skill was counterbalanced by his failure as a statesman, the justice of his provincial government by his coldness and arrogance at home, his freedom from the vices of the age by the readiness with which he divorced his wives. A deep dissembler, he lacked the real generosity which makes and retains friends, and, in the words of Merivale, 'was feared by all, admired by some, trusted by few, and loved by none.' See Merivale's *Fall of the Roman Republic* (Lond. 1853), and Mommsen's *Römische Geschichte* (5th ed. 3 vols. Berl. 1868-70).

Pompelmouse, **Pompo'leon**, or **Pumelo**, are names given to extra large fruits produced by some of the sub-varieties of *Cearus decumana* or Shaddock (q. v.).

Pompey's Pillar, a column standing on a mound 600 yards to the S. of Alexandria, is 98 feet 8 inches high, its shaft (73 feet) being composed of a single block of red granite. It was formerly surmounted by a figure of Diocletian, in whose honour, according to the inscription on its base, it was erected by Publius, eparch of Egypt, in 296 A.D. Its popular name is possibly a corruption of the Gr. *pompaios*, 'conducting,' applied to the pillar from the fact of its serving as a landmark.

Ponce, a town on the S. coast of the Spanish island of Puerto Rico, standing about 3 miles inland from its harbour, has a Catholic church in semi-Moorish style, an Anglican church (1874), a well-built townhall, a theatre with accommodation for 2000 people, and an hospital erected (1875) at a cost of £8000. The streets are lit with gas, and waterworks are now (1878) in course of construction. The steamers of the Royal Mail Company touch weekly at the port, and there is telegraphic communication with Jamaica and Santa Cruz. The exports (sugar, molasses, coffee, and tobacco) amounted in 1884 to £480,929; the imports (hardware, lumber, provisions, &c.) to £429,044. Estimated pop. (1877) 12,000.

Ponce de Leon, Luis, one of the most famous Spanish poets in the time of Karl V., was born at Granada of an illus-

trious family in 1527. He entered the Order of St. Augustine at Salamanca in 1544, and was appointed professor of theology there in 1561. In 1572 he was imprisoned for five years in a dark cell by the Inquisition for having translated the Song of Solomon contrary to the decree of the Council of Trent. He resumed his chair in 1577, was raised to the rank of vicar-general of the province of Salamanca, and died at Madrigal, 23d August 1591. A happy mixture of elegance, sensibility, and enthusiasm gives P. a foremost place among the lyric poets of Spain. He unites the glowing imagination of a Hebrew prophet to the artistic chastity of an ancient Greek. Long and close study of the classical models, and particularly of Horace, had refined his taste and polished his diction to a degree which has scarcely been attained to by any later Spanish poet. P. substituted a short rhymed measure for the long stanzas of the canzoni. His chief works published in his lifetime were *De los Nombres de Cristo* (1583-85); *La Perfecta Casida* (1583)—both of which are grand prose poems. His lyrics were first published by Quevedo at Madrid in 1631, under the title *Obras Proprias, y Traduccions Latinas, Griegas y Italianas; con la Paraphrasi de Algunos Salmos y Capítulos de Job*. A complete edition of his works appeared at Madrid (6 vols. 1804-16). See Nicholas Antonio, *Bibliotheca Hispana Nova* (2 vols. Rome, 1672); Ticknor's *History of Spanish Literature* (3d ed. 1861).

Pon'cho (Span.), a sort of cloak worn originally in Chili, consisting of a blanket with a slit in the centre, through which the head is thrust. Waterproof ponchos of painted cotton-cloth or rubber-cloth are used in the United States army, chiefly by mounted troops.

Pon'dicherry (*Puthucherry*), the chief French settlement in India, and the seat of government.—The town is situated on the Coromandel or E. coast of S. India, 86 miles S. of Madras. Estimated pop. 30,000. It is well built, and is divided by a canal into the White and Black quarters; there are boulevards lined with trees. The chief buildings are the Church of Foreign Missions, the Government House, and the lighthouse. The trade is not large, as the harbour is only an open roadstead, in which ships anchor one mile from the shore. In 1872-73 the coasting trade was thus valued:—Imports, £31,000; exports, £112,000. It has been proposed to connect P. with the S. Indian railway system. P. was the headquarters of the French at the time of their wars with the British in the Carnatic during the middle of the 18th c. It was then considered the handsomest city in India, with the strongest fort; but both were taken and razed to the ground by the British in 1761.—The district of P., which is entirely enclosed within the British district of N. Arcot, has an area of about 107 sq. miles, and a pop. of about 80,000. Along with the other French settlements in India, P. sends a member to the Chamber of Deputies.

Pondweed is a name given to the aquatic genus *Potamogeton* (Gr. 'near a river'), of which there are about 50 species. Of these, a considerable number are found in Britain, forming a large part of the subaqueous vegetation of the ponds, canals, streams, fresh and brackish ditches, and other waters of moderate depth. Some possess leaves that float on the surface over large areas, and so attract attention, while others only raise thin flower-spikes into the air for fertilisation, and are attractive merely to the naturalist. The properties are unimportant, though in the economy of nature the plants form food and home for much low animal life. An allied genus called *Zannichellia* bears the name of 'Horned P.' See NAIADACEÆ.

Pon'go, the name by which the Gorilla appears to have been first described by Purchas in his *Pilgrims* (1626). The third chapter of this work includes 'The strange adventures of Andrew Battell of Leigh in Essex, sent by the Portuguese prisoner to Angola, who lived there and in the adjoining regions neere eighteen yeeres.' Among other curiosities described by Battell is the 'ape monster Pongo.' There appears to be little doubt that the P. of Battell is the gorilla, the 'Engeco' being the chimpanzee. The term P. also appears to have been used to denote the Orang of the Eastern Archipelago, a monkey, it is hardly needful to remark, entirely distinct from the gorilla.

Poniatowski, a princely house of Poland, descended from the Italian family of Torelli, whose ancestors were Counts of Guastalla and Montechiarugolo. The first distinguished member of the family was Count Stanislaus P., born at Dereczyn

in Lithuania in 1677, who during the war of the Polish Succession was an active supporter of Stanislaus Leszczynski and Karl XII. of Sweden. After the death of Karl he went over to August II., but on his death again took the side of Leszczynski, and at the capitulation of Danzig was taken prisoner by the Russians. After his liberation P., at the request of Leszczynski, became reconciled to August III., whose confidence he henceforth enjoyed till his death at Ryki, in the Lublin Palatinate, August 3, 1762. P. left several sons by his second wife, the Princess Czartoryska, of whom, after Stanislaus August, king of Poland, the most noteworthy were **Prince Kazimierz P.** (1721-1800), Grand-Chamberlain to the latter; **Andrzej P.**, born 16th July 1735, who (1756) was made a prince of the German Empire, and at his death (March 3, 1773) was an Austrian general of artillery; and **Michal P.**, the youngest, who became Archbishop of Gnesen and Primate of the Empire, and whose sudden death during the rising of 1794 was popularly ascribed to suicide through fear on account of his unpopularity.---**Prince Jozef Antoni P.**, born at Warsaw, 7th May 1762, was the son of Andrzej P. and the Countess Kinska. He early entered the Austrian service, but in 1789 returned to his native country, where his untiring efforts as a major-general to improve the organisation of the Polish army were rewarded with the chief command during the campaign of 1792. When the king, his uncle, agreed to the Confederation of Targowicz, P. resigned his post and went to Italy, returning in 1794 to become a volunteer in the army of Kosciusko, who had formerly served under him. As commander of a division he did great service during the two sieges of Warsaw, and soon after the surrender of that town he retired to Vienna, from whence he returned in 1798 to live on his estates near Warsaw till 1806. On the erection of the Duchy of Warsaw in 1807, P. was appointed Minister of War. In 1809 he commanded the Polish army against the Austrians under the Archduke Ferdinand, and, though defeated (19th April) at Raszyn, by skilful manoeuvres forced the enemy to evacuate Poland, and penetrate Galicia as far as Cracow. P. was also at the head of the Polish contingent in the campaign against Russia of 1812-13, and on the 16th October of the latter year was appointed by Napoleon Marshal of France on the field of Leipzig. On the 19th he was ordered to cover the rear of the retreating French army. The victors had already occupied the suburbs of Leipzig, and planted light troops on the opposite bank of the Elster, when P., with now only 300 men and 30 horses, was forced to attempt its passage. The French troops had previously destroyed the only bridge, and P., severely wounded, spurred his horse into the river, and sank in its swollen waters. His body, found on the 24th and buried on the 26th, was afterwards removed to Warsaw, and in 1816 was re-interred at Cracow, in the sepulchre of the Polish kings. At Warsaw there is an equestrian statue of P. by Thorvaldsen. A monument erected (1814) at Leipzig by his comrades was in 1876 renovated by the Estates of Galicia.—**Prince Jozef P.**, natural son of Prince Stanislaus P. (born 23d November 1757, died 13th February 1831), who was the last legitimate scion of his house, was born at Rome, 21st February 1816, and educated at Florence. In his younger years he gained some celebrity as a tenor singer. Naturalised (1848) in Tuscany by the Grand-Duke Leopold II., he was Tuscan Plenipotentiary at Brussels (1849), and at London (1850-53). From 1854 he lived in France. Under the Second Empire he was made a member of the Senate, and was intrusted with several extraordinary diplomatic missions. In 1870 he removed to London, where he died, 3d July 1873. P. composed several operas, of which the most successful were *Giovanni di Proida* (1840), *Pierre de Médici*, *Don Desiderio*, and *A travers le Mur* (1861).

Ponsælion is the name of a new and beautiful scarlet pigment prepared by boiling cyanide of potassium with biniodide of mercury, adding a solution of caustic potash, and when cold bisulphide of carbon. The resulting precipitate passes rapidly through a variety of tints, and after a day's exposure to the air assumes a brilliant vermilion hue, which is permanent. P. was first obtained from Newcastle coals, and it derives its name from *Pons Aili*, the Roman Newcastle-on-Tyne.

Pont à-Mousson, an old picturesque town in the department of Meurthe, and the French frontier station on the line from Nancy to Metz, from the former of which places it is distant N.N.W. 20 miles. It stands on the Moselle, is over-

looked by a ruined castle on a lofty eminence, was for two centuries the seat of a university founded in 1571, and has a Gothic church of St. Martin dating from the 14th c. It carries on an active trade in coal, timber, grain, &c. Pop. (1872) 8211.

Pontchartrain, a lake of Louisiana, U.S., about 5 miles N. of New Orleans, which communicates with it by the P. Railway (one of the first constructed in the U.S.), and by two canals navigable by schooners. These canals do not enter the Mississippi, but terminate in basins in the rear of the city. The lake is 40 miles long from E. to W. and 25 broad, with an extreme depth of 20 feet. Almost surrounded by cypress swamps and *prairie tremblantes*, it is drained by the Rigolets and Chef Menteur first into Lake Borgne and then into Mississippi Sound. Forts Pike and Macomb defend these channels, through which is carried on an important commerce. Before the construction of the Mobile Railway, the traffic between New Orleans and Mobile, Pensacola, and the watering-places on Mississippi Sound was by steamer from the lake terminus of the P. Railway. Several places along the shores of the lake are much frequented by the people of New Orleans in the hot season. An immense boulevard between the lake and the city was being constructed in 1877. The lake is named after Comte de P., Minister of Marine under Louis XIV.

Pontecorvo, a town of S. Italy, province of Caserta, on a hill overlooking the Garigliano, 28 miles S. of Sora. It has old, massive walls, is the seat of a bishop, manufactures macaroni and plaster wares. The cathedral, adorned with fine frescoes, has valuable archives. The bridge here was destroyed to check the march of Hannibal, and the whole district is rich in Roman remains. In 1860 the bridge was again destroyed by the Bourbon troops, but was rebuilt soon after. Pop. (1874) 10,760. Napoleon conferred on Bernadotte the title of Prince of P. in 1806.

Ponté Delga'da, the most important seaport of the Azores, on the S. coast of St. Michael's Island, has now an excellent harbour, and is defended by St. Braz Bastle, and by two forts. It exports great quantities of the oranges for which the island is famous, and some wheat and maize. The orange crop of 1876-77 was much below the average, but in 1876 there entered 133 British vessels of 35,960 tons, and cleared 138 of 37,170 tons. The value of British imports was £49,127, and of exports to Great Britain £130,216. The port is yearly visited by a number of American whalers, for the purpose of taking in stores and landing oil for transshipment. A breakwater 860 metres long is (1878) in course of construction, on the model of that of Holyhead, and by 1875 a length of 580 metres was completed, at a total cost of £317,722. The part of the harbour thus formed has an area of 25,000 square metres, that not yet completed will have an area of 90,000 square metres, and a greatest depth of 60 feet. The new quay, at which vessels drawing 18 feet of water will be able to discharge, is to be 50 metres long. Pop. 20,000.

Pontefract (pron *Pomfret*), a town of England, in the W. Riding of Yorkshire, on a hill near the confluence of the Aire and Don, 10 miles S.E. of Leeds by rail. It was called Kirkby before the Conquest, but received its present name from the breaking of a bridge (*Pons fractus*) over the Aire, which long delayed the advance of William upon York, and the final blow of his terrible vengeance on Northumbria. Ilbert de Lacy, who received from William a grant of the place, subsequently built here a famous castle. In the 14th c., P. passed by marriage to Thomas, Earl of Lancaster, who, for having caused the death of Gaveston, was with many barons taken prisoner and beheaded in P. castle. In this castle, also, Richard II. was imprisoned and 'hacked to death'; Archbishop Scrope was beheaded in 1405; and Anthony Woodville, Earl Rivers, Lord Grey, and others were put to death by Richard III., to smooth his way to the throne. It was taken by Robert Aske at the head of the 'Pilgrims of Grace,' and in the civil wars, the last stronghold that held out for Charles I., it was finally dismantled by Major-General Lambert in 1649. The keep is the only part now remaining. As a municipal borough, P. is one of the oldest in the kingdom, dating from 1484; while as a parliamentary borough it is considerably older. It has a fine church of All Saints in Early English style, restored in 1867, and a Norman Church of St. Giles, the parish church since 1790.

P. is a great seat of the manufacture of malt and liquorice, and has flour-mills, iron and brass foundries, hat factories, breweries, brick and tile works, &c., while in the vicinity are numerous coal mines. New waterworks were opened in 1874. The well-known 'P. cakes,' lozenges of refined liquorice, have been made here for centuries, and are stamped with a rude figure of the famous castle. Eight cattle fairs are held yearly, and two race-meetings (on a good course a mile to the W.) during spring and summer. In the neighbourhood are kept the Badsworth Hounds. P. sends two members to Parliament, and publishes two newspapers. Pop. (1871) of municipal borough, 5350; of parliamentary, 11,653.

Pontevedra, capital of a province of the same name in Galicia, Spain, on a peninsula formed by the confluence of the Lerez, Alta, and Tomaso, 35 miles S. by E. of Santiago. The united rivers here enter the inlet called the Río de P., a magnificent natural harbour, and the Tomaso is spanned by a grand Roman bridge (*Pons vetus*), which gives name to the town. The great local industry is the sardine fishery. Pop. 6623.

Pontianak, a town of Borneo, and the capital of the Dutch Western Residency, on the W. coast of the island, and on the S. side of the estuary formed by the confluence of the Landak and Kapuas. The stream, here 300 yards broad, widens into a broad natural haven, known by the name of the town, and lined along both shores by dense forests, swarming with parrots and monkeys. The only buildings of any pretension are the residence of the native Sultan of P., the Dutch Residency House, defended by Fort du Bus, the hospital, and a mosque. The trade, which is increasing, is chiefly in the export of diamonds, gold-dust, sugar, rice, cotton, and coffee. The large country governed by the Dutch Resident is particularly rich in minerals. In Montrado district are the principal gold mines, the total yield of the Residency in this mineral being some 425,000 ounces yearly. The yield of diamonds has of recent years fallen off, but the fields of P. will always be remembered for having produced the famous gem of the Sultan of Matan, weighing 367 carats. Pop. of the town, 12,000, including many Chinese; of the Residency, in 1870, 337,772, of whom 312,565 were natives, 25,000 Chinese, and only 207 Europeans.

Pontifex, among the Romans, a member of the College of Pontifices, founded by Numa, and presided over by a P. Maximus, who held his office for life. The name is by some regarded as a form of *pompifex*, 'conductor of processions,' whilst others derive it from *pons*, a 'bridge,' and *facer*, 'to make' or 'sacrifice,' either because, according to Varro, the *pons sublimis* was built by the pontifices, or because on it they offered sacrifice. The college was originally composed of four members, besides the P. Maximus, all of them Patricians; but four Plebeians were added by the *Lex Ogulnia* (300 B.C.), and the number was subsequently raised by Sulla to fifteen, and by Cæsar to sixteen. Fifteen was the ordinary number under the emperors, who themselves held the office of P. Maximus down to the reign of Gratianus (375 B.C.). The pontifices did not devote themselves to the cultus of any one divinity, like the flamens, Salii, &c., or like the augurs to divination; they were the supreme ecclesiastical authorities, vested with the oversight of the whole body of religion, with the upholding of priestly rights (*jus pontificium*), and with the ordering of the calendar. Their formulas were contained in the *Libri Pontificales*, discovered on the Janiculum (181 B.C.). Self-election (*co-optatio*), the original mode of filling up vacancies in the College of Pontifices, was abolished by the *Lex Domitia* (104 B.C.), by which the right of appointing new members devolved on the *Comitia Tributa*. It was revived by Sulla (81 B.C.), again suppressed (63 B.C.), and finally restored by M. Antonius. In the Catholic Church the Pope's fourth title is 'Supreme Pontiff of the Universal Church.'

Pontifical is a book containing the offices properly used only by bishops (doubtless named after the *Pontifical books* of ancient Rome, which contained an account of the duties of the pontifices or priests, bishops having received the name of pontiff), and consists of three parts:—Relating (1) to persons, e.g., the administration of the sacraments, the benediction of various classes of persons, &c.; (2) to things, e.g., the consecration of churches, church-furniture, &c.; and (3) to different occasions, e.g., the publication of the movable feasts, &c. An authoritative collection of the various offices in use was first issued as a P. by

Pope Clement VIII. (1596); of which new and revised editions were published in 1644 and 1748. The Anglican P. consists of the offices for confirmation and ordination in the Liturgy.

Pontine Marshes (Ital. *Paludi Pontine*, Lat. *Pomptinæ Paludes*), a low, marshy district near the W. coast of Central Italy, extending S.E. from Nettuno to Terracina, a distance of 31 miles, and varying in breadth from 6 to 11 miles. It is separated from the sea-coast on the W. by low downs, and it is supposed that the origin of the P. M. is due to the silting up of the mouths of the small streams Nymptæus, Ufens, Amensius, and others, which at one time flowed through it from the Volscian hills. Pliny states that originally there were twenty-three cities in this plain; in 432 B.C. the 'Pomptinus Ager' is said to have yielded abundant corn; and in 312 B.C. the censor Appius Claudius led across it the celebrated Appian Way. But a century and a half later the P. M. had greatly increased, and an attempt was made to drain it by the consul Cethegus in B.C. 160. Subsequent efforts of Julius Cæsar and of Augustus were without success, and the P. M. were not reduced till the time of Pope Boniface VIII., who drained by a canal the land about Sezzo and Sermonetta. Pope Pius VI. in ten years (1778–88) succeeded in draining the greater part of the P. M., and reopened the Appian Way. Though the deadly Malaria (q. v.) which formerly infested the P. M. is now abated, the plain is still very unhealthy during the heat of summer. See Prony, *Morais Pontins* (1813), and Giordani, *Gita alle Paludi Pontine* (1872).

Pontoon (Fr. *ponton*, from Lat. *pons*, 'a bridge'), a portable floating vessel forming a support in the construction of bridges for military purposes. Boats were used to support timber platforms in the wars of the ancients, as by Darius in the bridging of the Bosphorus. Xerxes employed 674 vessels when he crossed the Hellespont. Pontoons of wood, covered with tin or leather, were extensively used in Germany and other countries in the 17th and 18th centuries. In the wars with the great Napoleon the British armies used pontoons of wood tinned inside and covered with metal, about 20 feet long, 5 feet broad, and 2 feet deep, a size which has not since been altered to any great extent, although great improvements in construction have been introduced. The pontoons were drawn up in line, and fastened to a couple of ropes drawn tightly across the river, being connected with timber baulks or joists upon which the flooring planks were placed. The late General Blanchard invented cylindrical pontoons of tin, which have the advantage of great lightness and buoyancy, most essential features in machinery which has to be transported from place to place. Rectangular frames are roped to the surface of the cylinder, on which rafts are formed. Captain Fowke, R.E., has invented a boat-P. of canvas on a wooden frame, which has increased lightness and surprising stability. The pontoons at present in use in the British service are of two kinds, both made of tin. One is cylindrical, with hemispherical ends, 22 feet 6 inches long, 4 feet wide, and 2 feet 4 inches deep. The other is of cigar shape, 14 feet 9 inches long, and 1 foot 7 inches broad. Rafts formed on two pontoons of the first kind are sufficient for the passage of troops and light ordnance; those formed on three pontoons at close distances for siege artillery. A raft of two pontoons can be formed in a quarter of an hour by half a dozen men, and dismantled in half the time. Pontoons are conveyed with their accompaniments in four-wheeled carriages. When they are not at hand, bridges are sometimes formed by groups of rough trunks of trees, lashed together, anchored in the river, and made fast by ropes stretched across the channel, baulks being applied as in a P. bridge. Casks are sometimes also used in the construction of military bridges. The Russians effected the crossing of the Danube at Galatz in June 1877 by a bridge of rafts lashed together longitudinally, other logs being laid crosswise upon them, to which was lashed another layer of longitudinal logs. On this was formed a roadway of planks wide enough for six men to march abreast. In the great crossing of the 27th June at Simniza, boat-loads of troops, protected by field-guns, first crossed the river, and after securing Sistova, an iron P. bridge was thrown across, upon which the main body passed over.

Pontus, a country in the N.E. of Asia Minor, bounded E. by Colchis and Armenia, S. by Cappadocia, W. by Galatia and

Paphlagonia, and N. by the Pontus Euxinus, from which it received its name. It was watered by the Halys (*Kizil Irmak*, 'red river'), Iris (*Kasalmak*), Thermodon (*Thernukh*), Acampsis or Apsarus (*Tihoruk*), and Phasis (*Rion*), and was surrounded by lofty mountain ranges which sent down spurs towards the sea. The immediate coast-lands, however, were level and of great fertility, yielding grain, fruits, and timber in abundance. Among its cities were Pharnacia (*Kirasunt*), Trapezus (*Trebizond*), Amisus, and Polemonium. P. was first raised to a kingdom by Ariobarzanes I. (363 B.C.), from the last of whose successors, Mithridates VI. (q. v.), it was wrested by the Romans (63 B.C.). It was formed into a province (63 A.D.), and under Constantine was divided into Helanopontus in the S.W. and Polemoniaca in the E.

Pontypool, a town of Wales, in Monmouthshire, at the base of the bold elevation of Mynydd-Maen, on the right bank of the Afon Llwydd, $8\frac{1}{2}$ miles N. of Newport by rail. In the reign of Charles II. the manufacture of japanned wares was introduced by Thomas Allgood, while his son invented the polishing process for the production of 'P. ware,' but both industries have been transferred to Birmingham. The inhabitants (4834 in 1871) are mainly employed in the adjoining coal and iron mines. P. publishes a weekly newspaper.

Pony (perhaps from 'puny'), a general name given to the various breeds of small horses. The best known varieties are the Welsh, Shetland, and Iceland ponies, other breeds being the Exmoor, Dartmoor, and New Forest ponies. These vary greatly in constitution and hardiness. The Shetland ponies are small and exceedingly hardy; the Welsh ponies are larger, and are also well adapted for travelling in mountainous districts. Ponies are generally far from docile, and require considerable care and patience in training.

Poodle (Ger. *pudel*), a breed of dogs of small size, and exhibiting great intelligence, docility, and affection. The fur is usually white, soft, and woolly. The P. appears to be derived from some of the water-dogs, although its exact derivation is unknown. A special variety of P., named the Barbet, has very long and silky hair.

Poodoo-Cottah (*Pulin-ke'ci*), the capital of a native state in S. India of the same name, in political connection with the Government of Madras, 220 miles S.S.W. of Madras. It has wide, clean streets, and is celebrated for the palace, temple, and tank, all in the same enclosure.—The *state* of P., which lies between the British districts of Madras and Trichinopoly, has an area of 1380 sq. miles; pop. (1874) 316,695; revenue, £50,000, of which two-thirds are alienated in feudal and religious grants. The country is well cultivated, and dotted with innumerable tanks, some of considerable size. The ruler, called Tondiman, is the only independent ruler on the Carnatic coast of Madras, a position he owes to the loyalty of his ancestors to the British. The administration is practically in the hands of the political agent at Trichinopoly.

Poole (Cymr. *Pwl*, 'a marsh' or 'lagoon'), a seaport of England, in Dorsetshire, $7\frac{1}{2}$ miles S. of Wimborne by rail, is situated on the N. side of P. Harbour. It has five churches, a guildhall, vegetable and fish markets, a public wharf, literary and mechanics' institutes, two banks, two weekly newspapers, &c. Cordage and sailcloth are largely manufactured, and there are good herring and plaice fisheries; but the yacht and ship building industry has greatly declined, only six British vessels of 292 tons having been built in the years 1872-76. P. Harbour, an irregular inlet, 6 miles long, formed by the projection of the 'Isle' of Purbeck, is one of the best havens on the southern coast. Since 1876 the narrow entrance ($\frac{1}{4}$ mile) has been improved, and the channel leading into the harbour deepened. In 1876 there entered 762 vessels of 75,218 tons, and cleared 857 of 73,237 tons. The imports in that year amounted to £147,676; the exports (chiefly grain and Portland clay) to £19,825; and the customs to £3443. P. had (1875) 65 vessels of 5925 tons, besides 80 fishing-boats. It returns one member to Parliament. Pop. (1871) 10,097. From a Roman road leading to Winchester, P. is supposed to have been a Roman port, but in Leland's time it was only a poor fishing village. It sided with the Parliament in the Civil War, and its fortifications were demolished at the Restoration.

Poole, Matthew, an English divine, born at York in 1624, studied at Emmanuel College, Cambridge, and in 1648 became minister of St. Michael-le-Querne, London. Ejected for nonconformity in 1662, he devoted himself to biblical studies, his great work, the *Synopsis Criticorum* (5 vols. Lond. 1669-76), being a condensation of the *Critici Sacri* (1660). His *Nullity of the Romish Faith* (1666) and *Dialogues between a Popish Priest and an English Protestant* (1667) led Oates to include his name in the list of persons marked for assassination by the 'Popish Plotters' (1678), and P. fled for security to Amsterdam, where he died in October 1679, 'leaving behind him,' says Wood, 'the character of *clarissimus criticus et casuista*.' His unfinished *Annotations upon the Holy Bible* was published with additions by his friends (2 vols. Lond. 1683-85).

Poole, Paul Falconer, R.A., a self-taught painter, was born at Bristol in 1810. He exhibited his first Academy picture, 'The Well, a Scene in Naples,' in 1830; his second, 'The Farewell,' in 1837, since which time he has been a regular exhibitor, being elected A.R.A. in 1846 and R.A. in 1861. His works, if somewhat defective in drawing and monotonous in colour, are strikingly original and harmonious. Among his later productions are 'Philomena's Song by the Beautiful Lake' (1867), 'The Spectre Huntsman of Onesti's Line' (1870), 'Imogen before the Cave of Belarius' (1871), and 'A Lion in the Path' (1873), the last a noble Poussinesque landscape.

Poonah (*Pind*), the chief town of the district of the same name, in the Presidency of Bombay, British India, and the former capital of the Mahrattas, is situated on a plateau at the foot of the W. Ghats, at the confluence of the Moota and Moulah streams, 1823 feet above the sea, 119 miles S.E. by rail from Bombay, and 58 N. of Sattara. Pop. (1872) 90,436; of the cantonments and Kirki, 28,430; total, 118,866. P. is the military headquarters of the Bombay army, and frequently the residence of the Governor during the hot months. It was never a fortified city. The chief building is the Peishwa's palace, a handsome quadrangle surrounded by cloisters of carved wooden pillars; it is now used as an hospital and lunatic asylum. The jail in the neighbourhood at Ynanda is a model structure. The cantonments, on an elevated site a mile W. from the town, are well laid out and healthy. They afford accommodation for 4000 European soldiers. In 1850, an elaborate system of waterworks was concluded, towards the cost of which £17,000 was spent by Sir Jamesjee Jejeebhoy. There are prosperous institutions for higher education, including the Deccan College, with 100 pupils and European professors. There is a large trade in the raw products of the country; but the business of the jewellers and weavers has declined. The chief manufactures are cotton and silk goods, gold and silver lace, and leather. A specialty of P. is the *sari* or woman's robe, finely woven of cotton or silk, and ornamented with a gold border after the *shikar* pattern. P. is first heard of in 1604, as granted to the grandfather of the founder of the Mahratta power, Sivaji the Great. Subsequently it became the capital of the Peishwa (q. v.), originally the minister of the Sattara Rajah, but ultimately the chief member of the Mahratta confederacy. In 1818 the Peishwa, who was bound by close treaties to the British, treacherously commenced hostilities by the battle of P. or Kirki; he was defeated and dethroned.—The *district* of P.—the original home of the Mahratta nation—lies within the Deccan, E. of the range of the W. Ghats. It has an area of 5099 sq. miles, and a pop. (1872) of 907,235. The country is much broken up by hill ridges. The crops are millets, rice, *ragi*, potatoes, cotton, and sugar-cane. There are manufactures of coarse cotton cloth and paper, and the *tussur* or wild silkworm is successfully cultivated.

Poon-Wood is the produce of two species of *Calophyllum* (q. v.), natives of the East Indies. *C. longifolium*, a large tall tree, common on the Aracan coast, &c., yields the true 'Poon-spars' of commerce, and *C. inophyllum*, which is of a much stronger and less elevated growth, furnishes a soft timber that is useful in shipbuilding where no great strength is required.

Poop (Fr. *poupe*, Lat. *puppis*), in large ships, a partial deck stretching aft from the mizzen-mast over part of the upper deck. The P. is passing out of use, being of no advantage great enough to make up for its increase of leeway in sailing, and of danger from the enemy in action. In Greek and Roman ships the

upper part of the P. carried a fan-shaped ornament (Gr. *aphlaston*, Lat. *aplustre*).

Pooral'iah (*Purulia*), the chief town of the district of Maunbhoom, Bengal, British India, 40 miles W. from Bancoora. Pop. (1872) 5695. The place is of no importance except as a British station. In the neighbourhood are some ruined stone temples of the Jains.

Poor'beah (*Pārbid*), a generic term of Sanskrit derivation applied to the inhabitants of India E. of the junction of the Ganges with the Jumna at Allahabad. During the Sepoy war of 1857-58 it came into general use in the British army for the Bengal mutineers, who were almost entirely recruited from the Provinces of Oude and Behar, to distinguish them from the native army of the two other Presidencies and from the Sikhs, who remained staunch.

Poor and Poor Laws. The word Pauperism (Lat. *pauper*, 'poor'), though almost unknown to the law, is used generally to indicate the settled condition of large masses of the people who are not only poor, but who are more or less dependent on the alms of the state. Among the nations of antiquity the charity resulting from religious dictate or natural feeling was in time displaced or supplemented by legislative decree. The kindly spirit of Old Testament injunction (*e.g.*, 'thou shalt not harden thine heart nor shut thine hand from thy poor brother,' Deut. xv. 7) lost its force in later times of widespread mendicancy. The hair-splitting refinements and definitions of Rabbinical writers on the law are collected in Maimonides' *Mishnoth Amin*, translated into Latin by Prideaux, under the title *De Jure Pauperis*. Athens, which at one time could boast of having no beggars, made provision for those maimed in battle, and later for the soldiers' orphans. The Greek republics had also many clubs or societies (*Etairei*) for mutual friendly relief. Among the Romans the extremes of wealth and penury were guarded against by the Agrarian and Licinian laws. (See AGRARIAN LAW and LICINIA GENS.) Caius Gracchus introduced the distribution of grain at reduced prices, and although Augustus (in whose time 2,000,000 were thus fed) tried to check the practice, it continued till the fall of the empire. Various Roman writers tell of its evil effects both on land and people. During the Middle Ages, the labourers in feudal countries were *villains* and serfs. In England, prior to any existing record, the great mass of the rural population had risen to comparative independence as peasant proprietors. Even the serf, though bound to the soil and in the strictest sense his lord's property, had acquired definite rights, and on the performance of service duly limited by custom his holding was quite secure. Under the Edwards money payments took the place of personal service, and thus was created a new class of free labourers. The scarcity of labour after the Black Death, and the lawlessness of the 'landless men,' led to the enactment of the Statutes of Labourers (1349), intended to re-attach the serfs to the soil and to control their wages. The statutes, even after the suppression of the Peasant Revolt, were utterly ineffectual, and only intensified the hatred between rich and poor, and created a mass of pauperism to be dealt with in later times. In a century and a half after the Peasant Revolt villainage had become obsolete, and the market was still in the labourers' hands. The great proprietors rapidly turned from tillage to sheep-farming, which required fewer hands, and the course of eviction to which this led greatly increased the free-labour class, and augmented the social danger of vagabondage. A policy of pitiless repression towards vagrants, begun in the Statute of Winchester in 1285, was continued till the enactment of 12th Richard II. (1388), which is the first statute for the relief of destitution. Without referring to the atrocious legislation of earlier reigns, we find the 14th of Elizabeth (only a few years before the passing of her famous 43d), after reciting that all parts of this realm 'be presently with rogues, vagabonds, and sturdy beggars exceedingly pestered, by means whereof daily happeneth . . . horrible murders, thefts, and other great outrage,' enacting that all vagrants, for a first offence, shall be grievously whipped and burned with an iron on the right ear; for a second, regarded as felons; and for a third, suffer death as felons without benefit of clergy. Strype says that every English county had from 300 to 400 vagrants living by theft and rapine. 'It was on this host of "broken men" that every rebellion could count for support;

their mere existence was an encouragement to civil war' (Green). In Henry VIII.'s reign, according to Harrison, 'threescore and twelve thousand great thieves, petty thieves, and rogues' were hanged, and in the earlier years of Elizabeth there were some 400 annual executions. Similar laws in various European countries were alike merciless. In the time of Elizabeth the issue of a royal commission enabled the Government to legislate more wisely and effectually, though still the main object of the laws was to protect society rather than to relieve the poor. As before, labour was enforced on the idle and settlement on the vagrant; but a distinction was made for the first time between these and the really impotent and destitute, while each town and parish was held responsible for the relief of its indigent and disabled poor, as it had long been responsible for the employment of able-bodied mendicants. Houses of correction were ordered for the punishment and amendment of vagabonds by means of compulsory labour, and the churchwardens were empowered to levy a general poor rate in each period. The well-known Act, 43d of Elizabeth, which matured and finally established this system, has been the base of pauper-administration till about a generation ago. Its great distinguishing principles are (1) a distinction between pauper and vagabond, and (2) local responsibility for local distress. The great social danger against which these Acts were directed now gradually disappeared, partly however owing to the development of new industries, which quietly relieved the glutted labour-market, and partly to the growth of wealth in the country. The great Act of Elizabeth had not taken effect up to the reign of Charles I. in some parishes, which simply ignored their poor, and assessed no rates. The 3d William and Mary (1691) remedied certain abuses of the unlimited power of churchwardens and overseers, and enabled the justices to grant relief in cases of emergency. Under the three Georges the overseers were made accountable to the parishioners by means of returns and inspection, and all out-door relief was abolished—an act which greatly increased the number of workhouses. But the 36th George III. (1796) repealed this last Act, and so extended the application of relief that by 1801 the rates had risen to £4,000,000, and by 1820 to £7,330,254. The commission of 1832 revealed the terrible evil of the allowances in aid of wages—wages fell, idleness increased, till in some parishes every labourer was a pauper. Farmers employed men from the parish at reduced wages, while idle paupers were better lodged and fed than industrious workers, and even than a large class of ratepayers. Marrying at the age of seventeen, paupers claimed relief on the day after their marriage. The recommendations of the commissioners, embodied in the 4th and 5th Will. IV. (1834), were (1) that out-door relief should cease; (2) that a central authority should control the administration; (3) that unions be established for the better management of workhouses and classification of inmates; and (4) that there be kept a complete system of accounts. In eight months 2066 parishes were merged in 172 unions. The operation of the Amendment Act was at once seen in the reduction of the rates from £6,317,255 in 1834 to £4,044,741 in 1837. It was found impossible to withdraw out-door relief, which is still paramount in England, but the exceptions to the general rule against allowance in aid of wages is rare, as in the case of the cotton famine of 1861. The last great change in poor-law administration was the exchange of the Poor-Law Board of 1847 for the Local Government Board in 1871.

Present State of Poor-Laws in England.—The Local Government Board consists of a president, appointed by the Crown, and certain *ex officio* members named in the Act. This board discharges the functions of the former Poor-Law Board and of the Home Secretary, and under the Acts relating to Registration of Births, Deaths, and Marriages, Public Health and Improvements, attends to sanitary matters and local taxation. It also discharges the duties of the Privy Council under the Acts relating to prevention of disease and to vaccination. The board has power to appoint officers with salaries, at rates to be determined by the Treasury. Any rule made by the board is valid if made under the official seal, and signed by the president or one of the *ex officio* members, and countersigned by a secretary or assistant-secretary. With regard to *Guardians of the Poor*, see that article. The term *workhouse* includes any house in which the poor of any parish or union is lodged. Commissioners may order workhouses to be built, with the consent of the majority of owners and ratepayers. Sums raised for the pur-

pose are to be charged on the rates; but are not to exceed one year's average amount. Loans are to be repaid in ten equal yearly instalments. Commissioners may order workhouses to be altered or enlarged without consent of the parish; but the cost must not exceed one-tenth of the year's rates, or £50. Introducing spirituous or fermented liquors into a workhouse, without the order in writing of the master, subjects the offender to a penalty of £10, or two months' imprisonment. The Act imposes penalties on paupers leaving a workhouse, carrying off clothes or other goods, on their refusing to work, or otherwise infringing the regulations of the workhouse. With regard to the emigration of paupers, see EMIGRATION, LAW REGARDING. Where Guardians (q. v.), select vestries, or similar bodies have been established, no out-door relief is to be given except as directed by them, subject to the control of the commissioners. But in sudden and extreme cases overseers may give temporary relief (not in money) to persons not settled in the parish. If an overseer refuse or neglect to give such relief, a Justice may order it, and an overseer disobeying the order is liable to a penalty of £5. A Justice may also give an order for medical assistance in case of dangerous illness. In any union two Justices may order out-door relief to any adult person unable to work from infirmity. The officials of a workhouse are bound to admit any one having an order from a competent authority. In extreme cases applicants must be admitted without an order, and if the house is full, must be accommodated elsewhere. A husband is liable to maintain the children of his wife, whether by previous marriage or illegitimate, till they are sixteen, or till the death of the mother. No pauper can be removed from any parish or workhouse till twenty-one days after notice of his being chargeable has been sent to the parish to which the order of removal is directed, unless the order be accepted. No removal can be made pending an appeal. A parish losing an appeal pays costs. No pauper can be removed from a parish after three years' residence. Legitimate children are settled in the parish of their parents. Illegitimate children have the settlement of their mother. A woman acquires the settlement of her husband; hence an Englishwoman marrying a native of Scotland or Ireland loses her claim to parochial relief in England. Apprenticeship gives a settlement in the parish where the last forty days were served. The putative father of a bastard child born after 10th August 1872 is liable to the mother in a sum not exceeding five shillings. Generally all property within the parish is rateable, but places of public worship are exempt. Money in anyone's house is not rateable, but personal property yielding an annual profit is so. The churchwardens and overseers have the power of fixing the rate. There are several Acts of Parliament specially applicable to the houseless poor of London. The rateable value of the metropolis is now (1878) considered to be about twenty-six millions sterling.

In Scotland, the relief of the poor is now administered under the Poor-Law Amendment Act of 1845. A Board of Supervision is established in Edinburgh, and assessments are imposed by the Parochial Boards. Usually owners and occupiers pay one half of the rate. It never falls wholly on the occupier as it does in England. In Ireland the P. L. is substantially the same as in England. See PARISH, CHURCH WARDENS, OVERSEERS, SETTLEMENT, &c.

In Foreign Countries.—There are only two countries in Europe, viz., England and Denmark, in which the poor are relieved exclusively by a special tax; and only three, Prussia, Denmark, and Sweden, in which there is a legislative declaration of the right of every destitute person to state support. Except in England and Denmark, the rates are supplemented by voluntary subscriptions and endowments. Differing in a marked way from England, most European countries give relief in kind as a rule. The Danish system, based on the Danske Lov of 1683, differs from that of most European countries in having been always entirely secular, but closely resembles the English system prior to 1834, and like it shows an abuse of out-door relief. In Sweden since 1871 the system has been based on the English law of 1834, and is more stringent than perhaps that of any other European country. It prohibits relief to the able-bodied, and makes masters liable for the relief of servants and labourers. The system in Norway, like that which prevailed formerly in Hamburg, and which still prevails in Elberfeld, is distinguished by minute subdivision of administrative authority for supervision and inquiry. As in Sweden, 'out-quarantening' (the *lægd*) is common, and here pauperism appears to be exceptionally low.

Although vagrancy was prohibited in Germany by a law as far back as 1497, none of the states forming the empire had any definite poor-laws till the beginning of the 18th c. The 'Law of Relief Domicile,' 1870, grants to every German the right to settle where he pleases, and allows a settlement for two years' residence. The whole country is divided into local unions, consisting of one or more communes. The central government has no direct control over them, but the Minister of the Interior has a sum (£96,000 in 1871) which he may distribute among overburdened unions. The systems in Leipzig and Elberfeld are noted mainly for strict personal investigation of cases. France has the most perfect charity organisation in the world, there being no compulsory relief except in cases of lunatics and deserted children. From the communal customs (*octroi*) the municipal councils vote subsidies; but the *octroi*, which is applied to many other objects, never comes to be regarded as a poor-rate. Outdoor relief is given through the Bureaux de Bienfaisance, indoor through the *hospitiaux* and *hospices*, of which together there were 1557 in 1869. All these establishments, no matter whence they derive their funds, are under State supervision and are purely secular. The *Sœurs de Charité*, who are salaried and are highly intelligent, visit in special districts and make minute reports to the Bureaux. In Belgium, a 'classic land of pauperism,' there is properly speaking no poor-rate, the burden being 'thrown upon private charity stimulated, husbanded, and regulated by the state.' In Italy communes are bound to maintain pauper lunatics and foundlings. Hospitals, almshouses, and asylums are very numerous (especially in Rome), and are supported by foundations and subscriptions, and managed by religious and other bodies. A law of 1862 ratified the power of the original managing bodies, subject to the general control of the state. In Russia, since 1864, under the new system of local government, the *zemstvos*, or representative assemblies, are entrusted with all funds and establishments for the relief of the poor, and can levy various taxes. St. Petersburg has an Imperial Society which relieves and classifies beggars, and a Grand Philanthropic Society, with branch committees in seven towns and a funded capital (1870) of £330,000, and real estate of £440,000. The latter society supports almshouses and schools, and grants medicines to the poor. See Reports of the Poor-Law Commissioners and Poor-Law Board (1835-72); Archbold's *Poor-Law* (12th ed. 1873); Emminghaus' *Das Armenwesen und die Armen Gesetzgebung in Europäischen Staaten* (Berl. 1870, Engl. trans. 1873); *Reports on Poor-Laws in Foreign Countries*, communicated by Her Majesty's Secretary of State for Foreign Affairs (1875); and J. Guthrie Smith's *Poor-Law of Scotland* (new ed. 1878).

Pooree (*Puri*, 'the city'), the chief town of the district of the same name, Bengal, British India, on the coast of the Bay of Bengal, 250 miles S.W. of Calcutta, and 595 N.E. of Madras. Pop. (1872) 22,695. Here is the far-famed temple of Juggernaut (q. v.), by which name P. itself was formerly known. The whole town is holy ground; and it is said to be crowded at the time of the *rath jatra*, or car festival, by 60,000 pilgrims. —The district of P. is the most southerly in Orissa, bordering on the Ganjam district of Madras. Area, 2473 sq. miles; pop. (1872) 769,674. It contains the Chilka Lake, an expanse of water bordering the sea, 334 sq. miles in extent. The staple crop of the district is rice, which is exported in ordinary years. In the famine of 1866, the loss of life was greater here than anywhere else. Salt is largely manufactured on the sea-coast by evaporation, and yields an annual revenue of £28,000.

Poor's Roll is, in Scotland, the roll of litigants who on account of poverty are allowed to sue or defend *in forma pauperis*. This privilege is conferred by the Court, on being satisfied of the poverty of the applicant, and that he has *probabilis causa litigandi*. The party has counsel and agent gratuitously provided for him, and is relieved from paying the fees of Court. The warrant entitling to the benefit of the P. R. remains in force for two years.

Popayan, a town in the United States of Colombia, finely situated at the base of the Western Cordillera, and on the river Cauca, 5750 feet above the sea-level. It was founded by the Spaniards in 1537, and in 1837 was nearly destroyed by the combined effects of an earthquake, volcanic eruption, and flood. Though of less importance now than in former days, P. is hand-

somely built and laid out, and possesses a cathedral college, and mint. Pop. 20,000.

Pope. See **RUFFE**.

Pope (Lat. *papa*, 'father,' i.e., of the church or the clergy) was, during the 3d and two following centuries a title common to all the bishops of the Western Church, and still common to those of the Greek Church. The Church was at first governed on republican principles, but as the clergy gradually assumed a position distinct from that of the laity, and especially after the Church was established by Constantine (324), its constitution came more and more to be formed on the model of the empire; so that the hierarchy of priests, bishops, metropolitans, and patriarchs corresponded with gradations in the civil power. And finally the Bishop of Rome, whose pre-eminence in the Church was the result of many concurrent circumstances, was gradually exalted into a position corresponding to that of the emperor. The Bishop of Rome held the same position relatively to the bishops of the whole empire as did the Metropolitans (q. v.) to those of a province. Disputes were referred to the See which was first in rank, and by a canon of the Council of Sardica (347) an appellate jurisdiction was allowed to the Bishop of Rome. Further, Rome was one of the most illustrious seats of the apostles; her bishops claiming to be the successors of St. Peter; and standing as they did in the forefront, had always to bear the first brunt of the various persecutions. Moreover, it suited the policy of the emperors to favour the establishment of a supreme patriarchal authority in their capital, as an instrument by which to control the Church. Thus Theodosius (409-450) in his Code and Valentinian III. (425-455) both enacted that the bishops were to be guided with regard to the customs of the Church by 'the P. of the Holy City.'

This development was also favoured by the Karoling monarchs, with whom the bishops of Rome entered into a close alliance. In return for the title of king bestowed on him by the P., Pippin (q. v.) undertook to defend the Holy Church against the Lombards. He accordingly compelled them to evacuate the territory called the Exarchate, which they had wrested from the Roman Empire, and causing the keys of the conquered towns to be laid on the altar of St. Peter, laid the foundation of the temporal power of the P. The alliance was no less close which existed between the P. and the succeeding German Emperors, who became as completely the liege lords of the popedom as the Karolings had been. When a vacancy occurred, ambassadors from Rome waited on the Emperor to receive his announcement of a successor. But at the same time it was naturally the personal interest of the Emperor that the P. should hold an important place in the eyes of the world. To have him acknowledged sole primate of the universal Church only enhanced the authority which the Emperor held over him.

Such was the state of affairs when Gregory VII. (1073-85) ascended the papal throne, and set about reducing to a perfectly organised system the idea of the supremacy of the Church over the State, and of the P. over the Church. His first step was to wrest the investiture of the P. from the hands of the Emperor. As the instrument for carrying out his purpose he made use of the Isidorian Decretal (q. v.), which had been published about the middle of the 9th c., and other forgeries of contemporary canonists, according to which every P. lawfully appointed was holy and infallible, no council could be held without his injunction, none but Ecumenical Councils were legal at all, and no speech could be held with an excommunicated man. This last article Gregory, in his *Dictatus*, translated into 'An excommunicated king is no longer fit to reign, and must be deposed.' The papal pretensions were further expanded and fortified by the *Decretum* of Gratian (about 1150), a manual of canon law in which the Isidorian forgeries and those of the Gregorian canonists were combined with additions of his own, and by which he forwarded greatly the grand scheme of making the Christian world the domain of the Pope-king. A significant sign of the effect of this work and of the progress made by the idea was that Innocent III. (1198-1216), who taught that the papal power is to the royal or imperial as the sun to the moon, changed the title of the P., which had hitherto been Vicar of Peter, to Vicar of Christ. Another idea developed at this time was that every Christian by the act of his baptism became a subject of the P.

Meantime the authority of the P. over the clergy within the

Church had been proportionally advanced. A great instrument in rendering the metropolitans dependent on the P. was the Pallium (q. v.), without which they could not discharge any ecclesiastical function. The popes began (about 600) by sending a pallium to certain bishops acting specially as vicars of the Roman See, and to all metropolitans. In 742 it was enacted by a council at Frankfurt that all metropolitans should request their pallium at the hand of the P., in token of their willing submission to the Roman See. This was construed by the popes into a promise of obedience before receiving the pallium, and was changed by Gregory VII. into an oath of allegiance. Having established their supremacy over the metropolitans, it followed of course that the popes had entire control over the ordinary bishops. The metropolitans were generally accredited as legates or vicars of the P., but more complete control was maintained by means of legates *a latere*, and when the Isidorian title 'universal bishop' gained its true significance at the beginning of the 13th c., the bishops were reduced to the position of mere helpers, delegates, and vicars of the P., to whom he assigned such a share of his rights as he thought fit; and they soon began to describe themselves as bishops 'by the favour of the Papal See.' The election of bishops had to be confirmed by their metropolitan, but men whose elections were disputed, as was often the case, began frequently to apply to Rome for confirmation. After that the popes began to confirm all episcopal elections, and then in certain cases to nominate the bishops themselves. Adrian IV. began with letters of commendation (1154). These letters, however, under Alexander III. (died 1181) assumed a tone of command, and under Innocent III. (1198-1216) were enforced, in spite of all opposition, by officers appointed for the purpose. It was decreed by Innocent III. (1215) that a see should not be vacant more than three months, and that those not filled up within the specified time lapsed to the P. *jure devolutionis*. Clement IV. claimed the right (1266) of appointing to all benefices vacated by the death of the incumbents while at Rome, *in curia vacantia*; the number of which was very great, owing to the great encouragement given in every way to go to Rome with appeals. From this time also the idea was advanced that the P. alone could sever the bond between a bishop and the Church on his resigning his office, and the principle established, which was afterwards made a rule by John XXII. (1316-33), that sees vacated by resignations lapsed to the P. On these various pleas Papal nominees were thrust in everywhere.

The rights of bishops, metropolitans, as well as of princes, having thus been usurped by the P., it remained for him yet to usurp those of the councils of the Church, by having it acknowledged that the infallibility of the Church in regard to faith and morals is vested not in the bishops collectively as the successors of the apostles, but in the P. alone, a doctrine which began to take definite shape in the 13th c. The first step in this direction had been taken by Gregory VII., when, in his *Dictatus* (about 1073), he declared that the P. was infallible. At the second Lateran Council (1123) Callixtus II. published the decrees in his own name, and the position of bishops in the councils of the 13th c. generally was simply to give their formal consent to the decrees of the P. The Mendicant Orders (q. v.), with their monarchical constitution, did most effective service in establishing the supremacy of the P., on which indeed their own privileges entirely depended; and it was a member of one of them—Thomas Aquinas (1224-74)—who sketched out the doctrine of Papal infallibility. That doctrine, however, was repudiated by the University of Paris, 1388, and a stand was made against it in the Councils of Pisa, Constance, and Basel (15th c.); but at the fifth Lateran Council (1512-17) Leo X. declared in the Bull *Pastor Æternus*, that 'the P. has full and unlimited control over councils.' Even after the Papal abuses and exactions had helped to bring about the Reformation, the supremacy of the P. over the Church and the kingdoms within its pale, and especially his infallibility, which was maintained in its fulness and formulated into a doctrine by Cajetan (about 1535), authoritatively promulgated by the Bull of Paul IV. (1558), and more distinctly defined in the Bull *In Cæna Domini* (1627), became the watchword of the Jesuits, who desired to see the whole Church organised on the principle of their own order. This theory, which found few adherents out of Italy till the Jesuits took it up, has received in modern times the name of Ultramontanism, in reference to the opposition to it which has prevailed chiefly in France (hence called Gallican-

ism, see GALLICAN CHURCH), Switzerland, and Germany, and which has given rise to the Old Catholic movement (see OLD CATHOLICS), and to a disruption of the Roman Catholic Church (1873). The reign of the late P. (Pius IX. 1846-78) formed an epoch in the history of the Papacy, for the infallibility of the P. was by an Ecumenical Council formally decreed to be a doctrine of the Church (1870), by a singular coincidence in the very year in which he was finally deprived of his temporal dominions.

The election of the P. from 'St. Linus' (St. Peter's successor) down to Nicholas II. in 1059, was in the hands of the whole Roman community—civil authorities, people and clergy. Throughout the 10th and earlier part of the 11th c. the Papacy had become a virtual possession of the dominant faction among the Roman nobility, and the scandalous contest preceding his own election was the immediate reason of the decree issued by Nicholas II., which, as Milman words it, 'wrested the power of nominating the P. from the lower clergy, the turbulent barons, and the populace,' and transferred it to the College of Cardinals. See Gieseler's *Lehrbuch der Kirchengeschichte* (Eng. trans. 1855); *The P. and the Council*, by Janus (Eng. trans. 2d ed. 1869); Döllinger's *Einige Worte über die Unfehlbarkeitsadresse* (Mün. 1870); *Erklärung an den Erzbischof* (Mün. 1871); Langen's *Das Vaticanische Dogma*, &c. (Bonn, 1871); Cardinal Manning's *Temporal Power of the P.* (Lond. 1876); and Wm. Arthur's *The P., the King, and the People* (1877).

Pope, Alexander, was born in London, May 21, 1688. His father, a Roman Catholic, having acquired a small fortune as a linendraper, retired in the year of his son's birth to Binfield, in Windsor Forest. P. was educated at haphazard. Having taught himself to write by copying out of printed books, he learned the rudiments of Latin and Greek from a priest named Banister; then he attended school at Twyford, where he was flogged for lampooning his master, and at London, where school-books were deserted for Dryden, Spenser, Waller, Ogilby's translation of Homer, and Sandy's translation of Ovid. When about twelve years old he enjoyed a momentary glimpse of Dryden, whom he ever revered as the greatest of his masters. Soon after he returned to Binfield, and there performed for himself the double duties of scholar and teacher until he reached the age of twenty. The *Ode to Solitude*, written when he was twelve, evinces the success of this peculiar training, or want of training. From his thirteenth to his fifteenth year he was engaged on an epic called *Alexander*, and wrote four books before burning it. A comedy and a tragedy were likewise destroyed; but his early satirical *Lines to the Author of a Poem entitled 'Successio'* (Elkanah Settle) were printed several years later in *Miscellaneous Poems and Translations* (1712). His first published work was his *Pastorals*, printed in the sixth volume of Tonson's *Poetical Miscellany* (1709). In 1711 the *Essay on Criticism* appeared anonymously, and received the heartiest abuse from John Dennis. In the following year P. contributed the *Messiah: a Sacred Eclogue*, to the *Spectator*. About the beginning of 1713 he resolved to turn painter, and actually studied for a year and a half under the care of Jervas, pupil of Kneller. But he soon returned to literature, after throwing away 'three Dr. Swifts, two Lady Bridgewater, a Duchess of Montague, half a dozen earls, and one knight of the garter!' In 1713 appeared *Windsor Forest*, written when he was sixteen, and an *Ode for Music on St. Cecilia's Day*. In 1714 he printed the extended version of the *Rape of the Lock*, a sketch of which had formed part of the *Miscellaneous Poems and Translations*. This carefully finished poem originated in a quarrel between two families on account of the attempt of a gallant to filch a tress from a reigning belle, Miss Arabella Fermor. A friendship with Addison induced P. to write a prologue for the first performance of *Cato*, and to defend that play from the attack of John Dennis in a *Narrative of Dr. Robert Norris concerning the strange and deplorable Frenzy of J. D.* Addison was by no means gratified by this defence; yet Pope continued writing for the *Guardian*, to which he had already contributed several papers.

Up to this time P. had lived on an allowance from his father: all his poetry together had not brought him £100. Upon the advice of Addison and Swift he now issued proposals for a poetical translation of the *Iliad*, to be published in six quarto volumes at a guinea each. 'The author shall not begin to print,' said Swift, 'until I have a thousand guineas for him.' Once pledged

to the public, 634 copies being quickly subscribed for, P. took fright, for his scholarship was small. 'Though I conquered the thoughts of it in the day,' he writes, 'they would frighten me in the night.' 'My usual method was to take advantage of the first heat, and then to correct each book, first by the original text, then by other translations, and lastly to give it a reading for versification only.' And so, more by the help of Latin and French than by that of Greek, the *Iliad* was translated in six years, 1715-20. Besides the subscriptions, P. received from Lintot, the publisher, £200 for each volume; and Dr. Johnson estimates his total profits at £5320. P. now set up as a man of fashion, but soon tiring of what to him was mere acting, he retired with his parents to Chiswick, where he published a collection of his poems (1717), in which appeared the *Elegy to the Memory of an Unfortunate Lady* and the passionate *Epistle of Elissa to Abelaud*. In 1718 he removed to a villa at Twickenham, whither he persuaded Lady Mary Wortley Montagu to come for a short time; but an acquaintance begun with ardour ended in mortification. Some say that P. proposed to Lady Mary in circumstances so ridiculous that she burst into uncontrollable laughter, and that P. ever after, as evinced in the coarseness of his satires, nursed towards her the most malignant hatred. In 1725 he brought out an edition of Shakespeare in six volumes. For this he got little money and less applause. Lintot, encouraged by his former speculation, engaged him to translate the *Odyssey*, and the work appeared in six vols. (1725-26). Although he only executed the half of this, the other half being the work of two hacks, Broome and Fenton, he earned by it £2885. 'It is a pretty poem, Mr. P.,' said Bentley, 'but you must not call it Homer.' In 1727 P., in conjunction with Swift, published three volumes of *Miscellanies*, in which was the *Treatise of Martinus Scriblerus on the Bathos*. The authors attacked in this treatise repaid the abuse in kind, and brought down upon their heads the greatest satire ever penned. The *Dunciad* (1728), for invention, variety of illustration, and scathing wit, is only approached by Dryden's *M-Flecknoe*; but it is now read with as much pity as admiration.

In 1731 appeared the epistle to Burlington *On Taste*; next year, his epistle to Bathurst *On the Use of Riches*. These are now the fourth and third of the *Moral Essays*, the first being the epistle to Cobham *On the Knowledge and Characters of Men* (1733), and the second, the epistle to Martha Blount *On the Characters of Women* (1735). The four epistles contained in the *Essay on Man* were addressed anonymously to Bolingbroke, 1732-34. In 1735 P. wrote a poetical *Epistle to Dr. Arbuthnot*. Curll the bookseller printed a collection of P.'s letters to Mr. Henry Cromwell in 1726; three years afterwards P.'s correspondence with Wycherley was published, and in 1735 appeared *Mr. P.'s Literary Correspondence for Thirty Years*. P. declared that this last was unauthorised, and brought out a genuine edition in 1737; but it is now discovered that in this case, as in some other cases, he was unscrupulous and vain enough to resort to forgery in order to gain a reception for his works. His last important poem was the *New Dunciad* (1742). With the help of Arbuthnot he began to collect his writings, but ere he had accomplished much he died at Twickenham, May 30, 1744. P. was the artist among poets. We read his writings with pleasing exhilaration, but with little glow of heart. No poet has ever excelled him in the combination of reason and fancy, concentrated meaning and melodious verse, playfulness and causticity of wit. The two highest orders of poetry, the epic and dramatic, he wisely left untouched. His attempts at lyrical poetry were few and unsuccessful. But he is the first of didactic poets. To him, moreover, we are mainly indebted for the development of English heroic verse. The classic editions of P. are Warburton's (9 vols. 1751), Bowles's (10 vols. 1807), Roscoe's (10 vols. 1824), Ward's (1873), and the Rev. Whitwell Elwin's, 5 vols. of which have appeared (1871-77). There are many biographies of P., from those of Ayre, Dilworth, Ruffhead, Johnson, to those of Bowles, Roscoe, and Carruthers (Bohn, 1857). See also De Quincey's essay on P., and Thackeray's *English Humourists*. A *Concordance of the Original Poetical Works of P.*, by Dr. E. A. Abbott, appeared in 1875. A German life of P., by Deetz, was published at Leipzig in 1876.

Poperinghe, a walled town of Belgium, province of W. Flanders, within 4 miles of the French frontier, and 10 W. of

Ypres by rail. It has manufactures of linens, woollens, lace, tobacco, and pottery, and a trade in hops, which are extensively raised in the vicinity. Pop. (1873) 10,868.

Popinjay, a term applied to the *Picus viridis* or green woodpecker. See WOODPECKER.

Popish Plot. See OATES, TITUS.

Poplar (*Populus*) is a genus of *Salicaceæ*—(see WILLOW), consisting of about twenty species of deciduous trees distributed through N. temperate regions. The flowers are dioecious, in lateral drooping catkins, with spirally arranged crenate or cut scales, each bearing one flower in its axil; the stamens are four to 30, the filaments free; the stigmas two to four cleft; the capsule has spreading valves. The leaves are generally broad, and those on shoots and suckers often differently shaped and clothed to those borne on the tree itself. Among the noteworthy species the following are the most important. *P. alba*—the albe or white P.—a native of Europe, N. Africa, and Middle Asia, often attains a height of 100 feet; furnishes a soft and light even-grained white wood, much used for packing-cases, for toys, for shoe-soles, and by turners for bowls, trays, &c. Its variety *P. canadensis* which gives a better timber for millwrights and carpenters, is probably indigenous in England, flowering in early spring before the leaves appear, and throwing up abundant root-suckers. *P. balsamifera*, the Tacamahac or Balsam P., is a native of Northern Asia, and N. America, forming a large tree with fine foliage, and diffusing a pleasant odour from the abundant balsamic juice of its buds, leaves, and branches; a tincture prepared from the buds is used medicinally in America. It is hardy in England, and often planted. *P. euphratica* ranges from the Himalaya to Syria, and occurs along ravines in Algeria. It forms a tree up to 50 feet high, the wood of which being harder and more compact than that of most poplars, is employed largely in some countries for beams, rafters, panelling, and turnery. Most of the lacquered Sindh boxes are made from it. The favourite habitat of the tree is along the banks of rivers, and on the Tigris and Euphrates its timber is used for planking and boat-building. This is the 'willow' tree of Psalm cxxxvii. *P. monilifera* or *Canadensis*, the cotton-wood tree of N. America, is of quick and luxuriant growth, attaining 100 feet, and yields a valuable timber. *P. nigra* or Black P. is native in Europe, and throughout Northern and W. Asia, preferring river banks or dampish ground. Is not indigenous in England, but is largely planted. The growth is rapid, and the light and soft wood is much used by joiners, coopers, turners, match-makers, and carvers, also for wooden shoes and superior charcoal. The bark serves for tanning, and in India the tree is often pollarded as cattle fodder. A variety with erect slender branches, known as the Lombardy P. (*P. pyramidalis* or *P. fastigiata*), is originally from Asia. It has long been cultivated in Italy, whence it was introduced into France in 1749, and into England in 1758, where it has been extensively planted as an ornamental tree. The female tree is barely known, so that it is propagated by layers, not by seed. *P. tremula* is described under Aspen (q. v.). The wood of this as well as that of the white and black P., have of late been much sought after for conversion into pulp for paper manufacture. *P. ciliata* is the aspen of India, its large leaves making a continuous fluttering noise with the least breath of wind, and *P. tremuloides* is called the N. American Aspen.

Poplin, a name borne by several varieties of plain or figured stuffs, having a silk warp, and a worsted, flax, or cotton weft, largely manufactured at Manchester, Dublin, and Lyon and other French towns. P., in name and substance, is derived from a French silk stuff, called *papeline*, because Avignon and other seats of its manufacture were situated in *papal* territory. On the introduction of the manufacture of papeline into England, the name became corrupted into P., and long-combed wool was substituted for the floss silk previously employed for weft. Irish poplins, known as *tabinets*, are much esteemed; their manufacture originated with French Protestant refugees, who settled in Ireland at the close of the 17th c.

Popocatepetl (Aztec, *popoca*, 'smoking,' and *tepetl*, 'a mountain'), a famous volcano of Mexico, 10 miles S.W. of Mexico city. It is conical shaped, 18,720 feet high, formed chiefly of

porphyritic obsidian, and clad with vegetation (dense forests in the lower levels) to a height of 13,000 feet, where the region of perpetual snow begins. It was active at the time of the Spanish conquest, but, though it still smokes, no eruption is recorded since 1540. Cortes failed in an attempt to reach the summit, but Francisco Mantano, one of his followers, succeeded, and was even lowered 450 feet into the crater by ropes. The brothers Glennie, who fixed the height of P. barometrically, ascended the mountain in 1827, and the feat has been performed repeatedly since.

Poppy (Old Eng. *papig*) is the genus *Papaver*, the type genus of the natural order *Papaveraceæ* (q. v.), and consists of about fifteen species of annual milky-juiced herbs, with lobed or cut leaves, solitary flowers on long peduncles, one-celled ovary, short capsule opening by very small valves under the lobes of the persistent sessile stigma, and small pitted seeds. They are distributed through Europe, N. Africa, and N. Asia, with one S. African and one Australian species. Four are more or less frequent in Britain, but, it is suspected, do not hold a higher grade of nativity than colonists. *P. Rhæas*, distinguished by its sub-globose glabrous capsule, in some parts renders the corn-fields a blaze of scarlet; *P. dubium*, with an obovate glabrous capsule, is also a frequent species; *P. Argemone*, with a clavate hispid capsule, is a smaller plant, with paler and less conspicuous flowers; and *P. hybridum*, bearing a globose prickly capsule, is the rarest, not reaching north to Scotland. But the most important species of the genus is *P. somniferum*, a glaucous

Papaver somniferum (Poppy).

plant with lobed or toothed amplexicaul leaves, large white or blue-purple flowers, an ovoid or globose capsule, and black or white seeds. Besides supplying Opium (q. v.), it possesses sufficient economic value to ensure its cultivation. The seeds yield by expression about 50 per cent. of a bland valuable oil of a pale golden colour, fluid to within 10° of the freezing-point of water. It dries easily, is inodorous, of agreeable flavour, and by simple exposure to the sun in a shallow vessel is rendered perfectly colourless. It serves as an article of food, as a fine oil for painters, and to adulterate the better qualities of medicinal, culinary, and ungual oils. The seed has no narcotic properties, but has a sweet taste, and is used parched in various countries as food, also by sweetmeat makers; it is the maw-seed given to cage birds. *P. orientale* and *P. bracteatum*, strong-growing perennials, natives of Asia Minor, are showy garden plants with red flowers, and are, with the peony, the largest flowered herbs grown in the open air in England.

In two allied genera *Meconopsis* (Gr. 'a P.' and 'resemblance') *cambrica* is called Welsh P., and *Glaucium luteum* bears the name of yellow-horned P., from its long and narrow curved capsule.

Medicinal Properties of P.—The nearly ripe capsules of the white P., *Papaver somniferum*, dried and deprived of their seeds, are used in medicine for purposes similar to opium. The pharmaceutical preparations are the *decoctum*, which is generally applied warm as a soothing agent. There is also an *extract*, the dose of which is from 2 to 5 grains. The *syrrup* is administered to adults in doses of 1 drm., and to children, 10 to 20 minims, increasing cautiously in consequence of their susceptibility to the influence of opium. The preparations of P. are of uncertain strength. The fresh petals of the *Papaver Rhæas*, the red P., are chiefly used on account of their colouring properties.

Poppy-Head, a finial ornament often used to terminate the upright ends of benches, &c. The earliest examples occur in the Decorated Style (q. v.), and are generally plain *fleurs-de-lis*. Later the P. took a variety of forms, and was often most elaborately carved.

Porbeagle, or **Beaumaris Shark** (*Isurus cornubicus*), a species of Shark (q. v.) somewhat resembling a porpoise in appearance, and attaining a length of 5 or 6 feet. The colour

is greyish-black above and white below. The P. feeds on fishes and molluscs. It has two dorsal fins, of which the first is set far forwards on the back. The muzzle is pointed, and the gill-openings are large.

Porcelain, a kind of ceramic ware, distinguished from common pottery by superior hardness of paste or body, a purer white colour, and some amount of translucency, owing to its being semi-fused by the high heat at which it is baked. The term is derived from the Italian *porcellana*, a cowrie-shell, owing to the likeness of its glazed surface to that shell. *Porcellana* again, comes from *porcella*, a little pig, from the fanciful resemblance of the cowrie to the pig. See POTTERY AND PORCELAIN.

Porcelain Crab, the general term applied to the members of the family *Porcellanidae*, in which the shell is smooth and porcelain-like. The *Porcellana platycheles*, or broad-clawed porcelain crab, is a familiar British species.

Porch, a small structure erected to shelter the entrance of a church or other edifice. The use of the P. dates from an early period. Many fine examples are found in Norman architecture. In the Decorated and Perpendicular styles, wooden porches of one storey are common; those of stone have often a chamber built over them, which was used as a chapel or a muniment room. At all periods the P. has been a favourite object of decoration. Those of the Norman style have their ornament chiefly on the inside and about the doorway, while those of later date are frequently decorated both without and within. Small chapels attached to churches are sometimes called a P.

Porcupine (*Hystrix*), a genus of Rodent mammals, having four molar teeth on each side of each jaw, imperfect collar-bones, and long spines or quills, as part of their body-covering. The P. has four toes and a rudimentary thumb in the fore feet, and five toes in the hinder feet. The muzzle is pointed. As in other Rodents, the incisor teeth are long, grow from permanent pulps, and are adapted for gnawing substances. In the true P. belonging to the genus *Hystrix*, the tail is not prehensile. The *H. cristata* is the common P. of S. Europe, N. Africa, and Asia. It has long spines capable of being erected or depressed at will, but which cannot be projected from the skin at will as was formerly supposed. An under coating of short bristly hair is developed, and the spines, often used for pen-holders, are marked with alternating bands of dark brown and white. The average length of the animal is about 2½ feet. The tail is short and is provided with short spines. The P. lives in burrows, and appears to hibernate in winter. The food consists of roots, &c., and the flesh is highly esteemed. The genus *Atherura* of Asia and the E. Archipelago has a peculiar tail-appendage of flat horny plates, representing modified spines. Of this genus the *A. fasciculata* is a good example. The P. of the New World belongs to the genus *Erethizon*. The Canadian P. (*E. dorsatum*) has short spines, and attains a length of 3½ or 4 feet. The Coendoo of S. America has a prehensile tail. Of this latter group the *Cercolabes prehensilis*, commonly known as the Brazilian P., is a familiar example. The tail is scaly towards its tip, and the average length of the body is 3½ feet.

Porcupine Crab (*Lithodes hystrix*), a species of crab occurring on the coasts of Japan, and so named from the numerous spines that everywhere spring from its shell and limbs. The hinder pair of legs are small. The northern spine crab (*Lithodes maia*) of the British coasts also belongs to the genus of P. C.

Pordenone, a town of N. Italy, province of Udine, on the right bank of the Noncello, near the base of the Alps, 50 miles N.N.E. of Venice by rail. It is supposed to be the *Portus Naonis* of the Romans, and was the birthplace of Giovanni Licinio da P. (q. v.), whose 'St. Christopher' is in the cathedral, a building begun in 1347. P. has also a fine Palazzo Comunale, the ruins of a noble castle, and of the old fortifications. There is ample water-power, and the manufactures are silk, cotton, ironwares, and pottery. Pop. (1874) 8269.

Pordenone, properly, **Giovanni Antonio Licinio**, one of the greatest of the Venetian fresco and oil painters, was born at Pordenone, in Friuli, in 1484, and was the contemporary and

the not unsuccessful rival of Titian and Giorgione. Many specimens of his best works are to be seen in the churches and mansions of Upper Italy; his noblest oil painting is the altarpiece in the church of Santa Maria dell' Orto, Venice; while in England he is represented by portraits and other subjects in the National Gallery, South Kensington, and in private collections. P. died in 1540 at Ferrara.

Porifera, a name formerly applied to the class of Sponges now known as that of the *Spongida* (q. v.), and included in the sub-kingdom *Protozoa*.

Porism (Gr. *porisma*, 'something deduced from a previous demonstration'), the name given by Euclid to two distinct kinds of mathematical propositions. The first corresponds to the class now known as *corollaries*, i. e., propositions involved in others, and obtained along with them, though having no direct bearing upon the principal object in view in establishing these others. The other class he collected on account of their great use in geometrical investigation; but beyond this, and a criticism of Pappus, we have no exact knowledge concerning them. Pappus pronounced them an ingenious and useful collection, and attempted a definition of them. But of this nothing remains save an adverse criticism on the definition given by some geometers, namely, that *Porisma est quod deficit hypothese a theoremate locali*. The succeeding account given is so fragmentary as to be almost unintelligible. The first successful attempt to reproduce them was made by Dr. Simpson, who published the result of his inquiries in 1746, and defined a P. as 'a proposition in which it is proposed to demonstrate that one or more things are given, between which and every one of innumerable other things not given, but assumed according to a certain law, a certain relation described in the proposition is to be shown to take place.' The meaning of this definition, which is somewhat obscure, may be best obtained from an example. Let it be required to divide a line so that the rectangle contained by the segments is equal to a given space; then it is evident that this is only possible when the space is not greater than the square of half the line. Or again, lines which by their intersection gave the proposition sought, might under certain conditions not intersect at all, or perhaps coincide, when of course the proposition would become indeterminate. These are simple instances; but in all similar cases the P. is the proposition which (first) asserts that the given proposition may become indeterminate, and (second) discovers the conditions by which this indeterminateness is brought about. It thus is neither wholly a problem nor a theorem, but is something intermediate, partaking of the nature of both.

Pork (Fr. *porc*, 'a hog,' from Lat. *porcus*) is the fresh uncured flesh of the domestic pig, *sus scrofa*. It differs very materially from other butcher meat in flavour, and in the large proportion of fat it contains as compared with the other constituents of flesh. As the animal is easily and cheaply kept, not subject to many diseases, and takes on flesh with great rapidity, P. can be produced with profit at a comparatively moderate cost. P. is not extensively employed in its fresh condition, but it is chiefly cured and preserved in various ways as Ham (q. v.) and Bacon (q. v.), being from its highly fatty nature specially well suited for use in these forms. Nevertheless, roast pig is esteemed a great luxury, and roast P. has also its admirers, while fried bacon, or ham and eggs, and boiled ham, are universal favourites. The fatty nature of P. renders it indigestible by some, but where it can be assimilated it is a valuable food, and especially serviceable where there is a tendency to phthisis. The following represents the composition of 1 lb. of P., judged from the composition of the entire carcass, as analysed by Lawes and Gilbert:—Water 6 oz. 69 grs., albuminoids 315 grs., gelatinous matter 385 grs., fat 8 oz., and mineral matter 105 grs.

P.-packing forms an immense industry in Chicago and Cincinnati, in the United States of America. Chicago possessed in 1876 sixteen 'P.-packeries,' which were occupied, during the winter season chiefly, in slaughtering 2,500,000 hogs for home and European consumption, while during the year ending February 1878 the enormous number of 4,009,311 animals passed through these establishments. The Cincinnati *Price Current's* twenty-ninth annual report of P.-packing in the West gives the hogs packed in the winter of 1877 as 6,505,000; 723,368 barrels; laid, 761,192 tierces; cured meats, 980,000,000 lbs; 9,048,566

bags were packed in the year ending 1st March 1878. In 1876 the P. imported by Great Britain from the United States amounted to 54,195,000 lbs.

Porosity (from Gr. *pōros*, a soft, friable, permeable stone, e.g., 'tufa'), in physics, is a property believed to be common to all kinds of matter, though particular substances, such as unenamelled porcelain, possess it to such a marked extent that they are distinguished as *porous*. Unless matter be perfectly homogeneous, or composed of atoms squeezed close to each other, suppositions for which there is not the slightest evidence, it must of necessity be porous.

Porphyry (Gr. 'purple') is a term vaguely applied to igneous rocks of the Trappian type (see TRAP). *Porphyrite* has a more restricted signification, including all the basic felspathic traps, just as *Felstone* is the name of the acidic group. See FELSPAR.

Porphyry, the arch-opponent of Christianity, was born about 233 A.D. at Batanea (Bashan), in Syria, his original name being Malchus (Melech, 'a king'), whence Aurelius styled him *Basileus*, and Longinus *Porphyrius*, 'purple,' the royal colour. As a youth he made the acquaintance of Origen at Cæsarea, and was perhaps his pupil, and at Athens he studied under Longinus and Apollonius. On his first visit to Rome (253) he had no opportunity of hearing Plotinus lecture, but during a subsequent residence (263-269) he became the attached disciple of the 'Father of Neoplatonism.' In 270, to divert the attacks of a settled melancholy, he travelled to Lilybæum in Sicily, passed on to Carthage, and, returning to Rome, succeeded to the chair of his late master. As his interpreter he was held in high esteem alike by senate and people, and died about 305 A.D. Predisposed by his Oriental birth and training for a fusion of East and West, for deepening the mysticism of the Neoplatonic philosophy, P. recognised the power of Christianity, but sought to counteract it by a spiritualisation of the ancient myths. From scattered notices of his fifteen books *Adversus Christianos*, composed in Sicily and destroyed by Theodosius, we gather that he had made a critical study of the Jewish and Christian Scriptures, the twelfth and thirteenth books being devoted to a minute examination of the prophecies of Daniel, in the course of which he anticipated several of the conclusions of Collins and the modern German rationalists. He saw the necessity of basing religion on divine authority, and accordingly supported the Pagan creed by oracles, and himself claimed to have beheld in his sixty-eighth year an ecstatic vision of the deity. But it is as the developer of the theory of predication that P. is perhaps most widely known, the text of scholastic speculation on this point being, according to Cousin, a passage from P. quoted by Boethius. Of fifty-six works by P., all in Greek, only nineteen have come down to us whole or in fragments, and these have not yet been published in a collected form. His *Vita Pythagoræ*, *Epistola ad Marcellum*, and *De Abstinentia ab Esu Animalium* have been edited by Nauck (Leips. 1860), his *Vita Plotini*, by Creuzer (Oxf. 1835), his *De Philosophia ex Oraculis haurienda*, by Wolff (Berl. 1856), &c. See Holstenius, *De Vita Porphyrii* (Rome, 1630); Neander, *Kirchengeschichte* (vol. i. p. 290, Hamb. 1825); and A. S. Farrar, *Critical History of Free Thought* (Lond. 1862).

Porpoise (*Phocæna*), a genus of *Cetaceans* or Whales, included in the Dolphin family (*Delphinidae*). The name P. is derived from the French *porc-poisson* ('sea-hog'); the Italian *porc-pesce*, and the German *meer-schwein* having the same meaning. In the genus *Phocæna*, both jaws are provided with teeth, and the dorsal fin is triangular, and placed towards the middle of the back. The common P. (*P. communis*) is one of the most familiar of the Cetacea, and is very common around the British coasts. It is a dreaded enemy of most of our food fishes, and pursues the salmon and herring with avidity. The average length of the P. is seven feet. Its colour is a bluish black on the upper parts, and silvery white below. The head of the P. is blunt, and is not developed to form a muzzle, as in the dolphin. The young are large even at birth. The nostrils are united to form the single 'blow-hole,' which is of crescentic shape, and placed above the eyes. The P. is gregarious. The skin is exceedingly thick, and much valued for making a strong, durable leather. The blubber attains a depth of about an inch, and affords an oil. The flesh is not unpalatable, but its dark-coloured appearance must have tended to

place it in disrepute. The Cape P. (*P. Capensis*) inhabits the S. African Seas; and the Grampus (*P. orca*) is nearly allied to the P.

Porpora, Nic'olo, a musician, born in Naples in 1689, died in 1767. He was a pupil of Scarlatti, and the composer of about fifty operas and a number of religious compositions, which, though now but little known, were received with great favour at the time. His style in recitative has always been highly esteemed. See Fétis, *Biographie Universelle des Musiciens* (new ed. 1878).

Porridge (a corruption of *pottage*!), is a very nutritious article of food, made from oatmeal by sprinkling it in boiling water, slightly salted, and constantly stirring till the whole thickens. It is usually eaten to breakfast with milk, butter, or treacle, and is a favourite diet of the Scottish peasantry.

Por'sena, or **Porsenn'a**, **Lars**, king of Clusium in Etruria, is known to readers of Livy as the monarch to whom Tarquinius Superbus applied for help when expelled from Rome. Responding to the call of Tarquinius, he marched on Rome with a large army, and pushed the Romans across the Pons Sublicius without striking a blow. But although the Roman guards thus deserted their post, the Etruscans were foiled by the bravery of a single man, Horatius Cocles. By his single arm he stopped the narrow entrance to the bridge until it was broken down behind him, and then swam across the Tiber to the city. The attack became a siege. One day, as P. sat in his tent, his secretary was struck down by his side; and the assassin proved to be a Roman. This was Caius Mucius Scaevola, who boldly declared that his intention had been to kill the king, and affirmed that 300 noble Romans were under oath to accomplish P.'s death. Perceiving the determination of the citizens, P. is said by Livy to have accepted hostages, and returned to Clusium. From the hints, rather than from the plain statements of other historians, it would appear that Rome was actually subdued by the Etruscans. The Romans certainly lost the lands they had taken from the Veientes, and Niebuhr concludes that these lands were seized by the conqueror's strong hand.

Por'son, Richard, born at East Ruston, in Norfolk, on Christmas Day 1759, was educated by his father, a weaver and parish clerk, and at the village schools of Bacton and Happisburgh, till in 1771 Mr. Hewitt, the curate of the parish, offered to teach him gratuitously along with his own boys. Under him the lad made such rapid progress that in 1774 Mr. Norris, a neighbouring squire, was induced to raise a fund for sending him to Eton, where he remained four years without acquiring much beyond a facility in Latin verse-making. Proceeding to Trinity College, Cambridge (1778), P. gained a foundation scholarship (1780), graduated as third senior optime and senior medallist (1782), and was elected a fellow of his college (1787), under the obligation to resign at the end of ten years unless he should enter holy orders. A course of theological reading soon convinced him that he could not conscientiously subscribe the Thirty-Nine Articles; he resigned his fellowship in June 1792, and five months later was unanimously chosen Greek professor, with the munificent stipend of £40 a year. Meanwhile his reading had brought him across Travis' *Letters to Gibbon*, on the disputed text of 1 John v. 7, and these evoked his celebrated *Letters to Archdeacon Travis* (1790), a work which, though admirable for its critical acumen and masterly English style, was looked on as an attack upon Christianity, and lost its author a valuable legacy. P.'s means were miserably straitened at this period, and he would walk from Cambridge to London to avoid the expense of coach-hire, whilst in London a guinea lasted him for an entire month. Worse than poverty, however, was an insatiable craving for drink—brandy by preference, but if that could not be got, ink, embrocation, spirits of wine, or even water. In 1792 P.'s friends raised him an annuity of £100, and in 1806 he was appointed principal librarian to the newly-founded London Institution, with a salary of £200. This post he filled, or rather neglected, for barely two years, being seized with apoplexy in the Strand, September 19, 1808, and dying on the 28th following, at the early age of forty-nine. His meditated editions of *Æschylus* and *Aristophanes* had come to nothing; of Euripides he only edited four plays, the *Hecuba* (1797), *Orestes* (1798), *Phanissa* (1799), and *Alceæ* (1802); and his remaining works were limited to a few scattered articles in *Maty's Review*,

the *Monthly Review*, the *Gentleman's Magazine*, and to the posthumous *Adversaria* (1812), and notes and emendations on Pausanias (1820), Photius (1822), and Suidas (1834). Some dozen capital *bon-mots*, a few quaint anecdotes, and a picture of wasted opportunities, in which unswerving honesty is the single redeeming feature, are all that we now remember of him whom his contemporaries described as 'one of the profoundest Greek scholars, and the greatest verbal critic that any age or country has produced.' See J. S. Watson's *Life of Richard P.* (Lond. 1861).

Port, in naval language, denotes either (1) a harbour for receiving or discharging cargoes; (2) an opening in a ship's side for a gun, also called a P-hole (q. v.); or (3) the 'Larboard' (q. v.) side of a ship, the left hand to one looking towards the bow.

Portadown (Irish Gael. *Port-a-Dilin*, 'port of the fort'), a market-town of Ireland, in the county of Armagh, 21 miles W.S.W. of Belfast by rail, on the Bann, which is here navigable for vessels of 60 tons. It has one Anglican, two Roman Catholic, and three Presbyterian churches, and one weekly newspaper. There are manufactures of cotton and linen goods, and a trade in grain, flax, pork, butter, &c. In 1873 the town revenue was £830 and the debt £720. Pop. (1871) 6375.

Portal, in architecture, the arch over a gate or doorway. The term is sometimes loosely used for Porch (q. v.).

Portal Veins, the system of veins existing in Vertebrate animals for the purpose of conveying blood to the Liver (q. v.), for the manufacture or secretion of bile. This system of veins consists of four trunks, receiving the venous blood from the digestive system. These four trunks are the *inferior* and *superior mesenteric*, *splenic*, and *gastric* veins. The single vein (*vena porta*) formed by their union enters the liver. It is destitute of valves. The splenic and gastric veins unite with the other two veins, the inferior and superior mesenteric; and these two in turn unite to form the *portal vein*. The union of the two mesenteric veins takes place in front of the vena cava, and behind the upper border of the larger extremity of the *Pancreas* (q. v.) or sweetbread.

Portamen'to, in singing, is the gliding from one note to another; *P. della mano* (in pianoforte playing), the management of the hands.

Portarlinton, a market-town of Ireland, chiefly in Queen's and partly in King's County, and on both banks of the Barrow, near a branch of the Grand Canal, 4½ miles S.S.W. of Dublin by rail. The river is crossed by two bridges, and the chief buildings are the fine English church, the so-called French church, and a Roman Catholic Church with a spire 140 feet high. There are several good schools, at one of which the Duke of Wellington and his brother Lord Wellesley were pupils. P. has eight fairs yearly, and manufactures leather, tobacco, soap, and candles. It returns one member to Parliament. Pop. (1871) 2424. P., the old Irish *Coolteodra*, took the name of Lord Arlington, to whom it was granted by Charles II. Sold to Sir Patrick Traill, it was, on his attainder, granted by William III. to General de Rouvigny, who introduced a number of French and Flemish refugees. The town and estate were subsequently purchased by the Dawson family, who were created Earls of P.

Port Arms (Lat. *portare*, 'to carry'), a movement in musketry drill in which the rifle, held in the right hand, and supported by the left arm, is laid in a horizontal position across the chest.

Port-au-Prince (Sp. *Vera Paz*), the capital of Hayti, on the W. coast, at the head of the Bay of Gonaves. Despite its prepossessing look from seawards, it is ill-built, squalid, and unhealthy. The streets are cumbered with refuse, and the harbour is obstructed by mud-islands overgrown with mangrove shrubs. The chief buildings are the president's house, the senate-house, the hospital, college, lyceum, and the Petit Seminaire, with 318 pupils in 1876. A terrible fire destroyed the best part of the town in February 1875. P. is the seat of a Roman Catholic archbishop, and exports coffee, cocoa, cotton, mahogany, Campeche and other woods. In 1876 the exports amounted to \$3,267,326, the imports to \$5,243,161. In the same year there entered the port 305 vessels of 284,112 tons, and cleared 296 of 273,317. Pop. (1877) 20,000.

Port Blair, the chief town of the Andaman Islands, and the headquarters of the Indian convict settlement. The penal settlement contains 7000 prisoners, arranged in six classes, and employed in clearing jungle, cultivation, &c. The annual cost is about £100,000. It was on the pier of the harbour at this place that Lord Mayo, the Governor-General of India, was stabbed by a Mohammedan convict from the N.W. frontier on 23d February 1872.

Port Canning, a now almost deserted town in the district of the Twenty-four Pergunnahs, Bengal, British India, on the Mutlah mouth of the Ganges, 28 miles S.E. of Calcutta. It was founded in 1853 by a private company, aided by Government, at a time when it was thought that the main stream of the Hoogly was in danger of silting up. The shares of the company immediately became the subject of much illegitimate speculation. After an expenditure of more than £100,000, the enterprise was finally abandoned in 1870. A railway still runs from Calcutta to P. C., but it is worked at an annual loss to the Government, its proprietors.

Portcullis (Fr. *porte*, 'a gate,' and *coulisse*, 'something that slides down,' from *couler*, 'to flow' or 'glide'), a narrow-shaped frame of wood or iron, formerly much used in the defence of fortified places. It hung over the gateway, and in case of an assault was made to slide down a vertical groove in the jambs of the gate. In heraldry the P. has rings at its upper angles, from which chains are hung.

Port Durban, or **Port Natal**, the oldest and largest town and only seaport in the colony of Natal, on the shores of an inlet 3½ miles long and 2½ miles wide. The entrance to the harbour is impeded by a bar, which the best engineering skill has hitherto failed to remove. The town is well built and laid out, and among its most agreeable features is its beautiful botanical garden. Pop. (1877) 10,488.

Port Elizabeth, an important town in S. Africa, situated at the W. extremity of Algoa Bay (q. v.). It was founded in 1820, and named after the wife of Sir R. Donken, who was Lieutenant-Governor of Cape Colony at the time. P. E. is the most English town in S. Africa, and the buildings in its principal line of street, which is two miles long, will bear comparison with those of much larger towns in Britain. The water supply, however, is deficient, and the lack of trees gives the town a bare appearance when viewed from the sea. The educational institutions of P. E. are numerous and efficient, the chief among them being the Grey Institute, which consists of a high school and three elementary schools. It was inaugurated by Governor Sir George Grey in 1854, and is supported by a land endowment. P. E. is commercially the most important town in S. Africa, its trade being double that of Cape Town. The principal articles of export are wool—of which 35,428,634 lbs. were exported in 1874—skins, hides, horns, and ostrich feathers. The commercial importance of P. E. has been attained in spite of great natural disadvantages, goods requiring for a long time to be landed and shipped by means of surf-boats. Jetties now exist, but as the bay is exposed to heavy S.E. gales, a breakwater is necessary. A wooden one was constructed some years ago, and proved of great service till it was rendered useless by the sand silting up within it. Plans by Sir John Coode for overcoming the difficulty, though at great cost, are likely to be adopted. A line of railway connects P. E. with Uitenhage, 18 miles N. Pop. (1875) 12,974.

Porte, **Sublime**, the name given to the Turkish Government. The origin of the term lies in the Oriental custom of holding courts, conclaves, &c., at the gates of cities, palaces, &c., the S. P., which is the French for 'lofty gate,' being applied first to the high doorway of the Sultan's palace, and afterwards to his government generally. The universal employment of French as the diplomatic language throughout Europe explains the currency of the term in its French form.

Porter, a variety of malt liquor or Beer (q. v.), characterised by a fine dark brown colour, a mellow, bitter, and peculiar burnt-like taste. The beverage originated in London in the early part of the 18th c., and took its name from having been at first a favourite liquor with the street porters and labouring population. It however rapidly gained in popular estimation, and is now a much-used beverage. The best P. still continues

to be made in London, after which Dublin P. is highly esteemed. Good London P. contains about 6.4 per cent. of alcohol, and nearly a similar amount of saccharine and extractive matter; 'stout,' which is a richer beverage, has about 7.3 per cent. of alcoholic strength.

Porter, David Dixon, an American naval commander, born in Pennsylvania, June 8, 1814, is the youngest son of Commodore P. (1780-1843), who as commander of the *Essex* distinguished himself in the war with England (1812-14). After two years' service in the Mexican navy, he entered that of the U.S. (1829), passed his examination (1835), and was employed in the coast survey till 1841, when he obtained his lieutenancy. Placed on special duty at the Washington Observatory (1845), he resigned this post in the succeeding year for active service in the Mexican war, and in 1861, on the outbreak of the Civil War, was despatched with the rank of commander to the relief of Fort Pickens. Having next commanded the mortar-flotilla at the reduction of the forts below New Orleans, and at the unsuccessful siege of Vicksburg, P. was appointed, in October 1862, acting rear-admiral of the Upper Mississippi squadron, and co-operated in the second and successful attack on Vicksburg. In 1864 he was transferred to the Atlantic coast, where he effected the capture of Fort Fisher; in 1866 was promoted vice-admiral, and in 1870 succeeded Farragut (q. v.) as admiral of the U.S. navy, a post which he still (1878) retains.

Porter, Noah, D.D., an American philosopher and author, born at Farmington, Connecticut, December 14, 1811, graduated at Yale College (1831), was a schoolmaster at New Haven (1831-33) and a tutor at Yale (1833-35). He became pastor of the Congregational church at New Milford (1836), removed to Springfield (1843), and was chosen Clark Professor of Metaphysics and Moral Philosophy at Yale College (1846), succeeding Dr. Woolsey in the presidency of that institution (1871). A scholarly metaphysician, and in particular well versed in modern German philosophy, P. has written *The Educational Systems of the Puritans and the Jesuits Compared* (1851), *The Human Intellect* (1868), *Books and Reading* (1870), *Elements of Intellectual Philosophy* (1871), *The Science of Nature versus the Science of Man* (1871), &c.

Porter, Sir Robert Ker, K.O.H., an English artist and traveller, brother to the novelists Jane and Anna Maria P., was born at Durham in 1780, and became a student in the Royal Academy in 1790. Two years afterwards he produced his first large work, 'The Storming of Seringpatam,' which was followed by 'The Siege of Acre,' 'The Battle of Agincourt,' 'The Battle of Alexandria,' and 'The Death of Sir Ralph Abercromby.' In 1804 he visited Russia, was created historical painter to the Emperor, and executed some important works, including the decoration of the Admiralty Hall at St. Petersburg. Here he became acquainted with the Princess Mary, daughter of Prince Theodore von Scherbatoff, whom he married in 1811. After accompanying Sir John Moore throughout the Spanish campaign to the final catastrophe at Corunna, P. returned to England, where he was knighted by the Prince Regent in 1813. From 1817 to 1820 inclusive he was occupied in making those extensive travels in Asia, of which he has given an interesting and valuable account in his work *Travels in Georgia, Persia, Armenia, Ancient Babylonia, &c.* (2 vols. 1821-22). From 1826 to 1841 he resided as consul at Caracas, Venezuela, where he painted three of his best pictures, viz., 'Christ at the Last Supper Blessing the Cup,' 'Our Saviour Blessing the Little Child,' and an 'Ecce Homo.' In 1841 he revisited St. Petersburg in company with his sister Jane, and died there, May 4, 1842. His other books are *Travelling Sketches in Russia and Sweden* (2 vols. 1808); *Letters from Portugal and Spain, Written during the March of the Troops under Sir John Moore* (1809); and *Narrative of the late Campaign in Russia* (1813).—**Jane P.**, sister of the preceding, was born at Durham in 1776, and educated at a school in Edinburgh, and afterwards in London. In 1803 she published her first novel, *Thaddeus of Warsaw*, which was translated into several languages, and led to her being afterwards elected 'lady patroness' of the Teutonic order of St. Joachim. In 1809 appeared *The Scottish Chiefs*, which greatly added to her fame as a 'historical' novelist. The best known of her other works

are *The Pastor's Fireside*; *Duke Christian of Luneburg*; *The Field of Forty Footsteps*; *Sir Edward Seaward's Diary*. She also wrote along with her sister *Tales Round a Winter's Hearth*. In 1842 she went with her brother to St. Petersburg, returning to England after his death. She died at Bristol, 24th May 1850.—**Anna Maria P.**, sister of the two preceding, was born in 1780, and died at Bristol, 21st June 1832. Like her sister, she wrote tales chiefly of a historical character, of which the principal are *Octavia* (1798); *The Hungarian Brothers* (1807); *Don Sebastian* (1809); *The Barony* (1830), and *Artless Tales* (1793).

Portfire, in artillery, a case of paper, usually about 16 inches long, filled with a composition of saltpetre, sulphur, and mealed gunpowder, used for firing guns. This P. burns at the rate of a little more than an inch per minute. Paper impregnated with saltpetre and rolled into a solid cylinder of 16 inches makes a slow P., burning from two to three hours. Paper dipped into solution of nitre, two ounces to the gallon, and rods of wood boiled in a solution of nitrate of lead and subsequently in spirits of turpentine, are also used.

Port Glasgow, a thriving seaport of Scotland, in Renfrewshire, on the S. bank of the Clyde, $2\frac{1}{2}$ miles E.S.E. of Greenock, and 20 N. by W. of Glasgow, on the Glasgow and Greenock Railway, which is here carried across the beach on a viaduct. The Clyde is here $2\frac{1}{2}$ miles wide, but its bed is in great part dry at low water. Immediately behind the town two successive ridges rise to a height of 400 feet, their steep slopes clad with trees. The place was the property of the Maxwells, till in 1668 it was bought by the Corporation of Glasgow to form an outer port for that city. It was made the chief customhouse port for the Clyde in 1710, a municipal borough in 1775, and a parliamentary borough in 1832, in association with Kilmarnock, Rutherglen, Dumbarton, and Renfrew. Although much of its commerce has been diverted to Greenock and to Glasgow since the deepening of the Clyde, the place is still of importance, and its trade, both coasting and foreign, is now increasing. In 1878 the harbour, consisting of three docks, had an area of about 5 acres, and there was a total of 1000 yards of wharfage. The ship-building yards are extensive, and are provided with the newest appliances for the construction of large vessels. In 1876 they turned out 53 vessels of 27,406 tons. On 1st January 1875 the port was incorporated as an out-station with that of Greenock, but according to the last separate returns for 1874 there entered the port 330 vessels (with cargoes only) of 52,415 tons (225 steamers of 10,797 tons), and cleared 145 of 56,760 tons (69 steamers of 11,961 tons). In 1874 the imports amounted in value to £282,990, the exports to £70,462, and the gross customs revenue to £1185. P. G. has a large export trade; manufactures cordage, sailcloth, chain-cables, and anchors. Pop. (1871) 10,823. In the vicinity is Newalk Castle, the interesting old seat of the Maxwells.

Porthole, in naval language, denotes the opening in a ship's side from which guns are pointed. The P. is usually square, and must be wide enough to allow of the guns being pointed at different angles. In a ship at sea it is defended by hinged covers, the rope fastening these being called 'port lanyards.'

Portici, a town of S. Italy, province of Naples, on the W. slope of Vesuvius, 5 miles S.E. of Naples by rail. It has a small harbour formed by a mole and defended by a fort. The high-road from Naples to Salerno traverses the town, and leads through the court of the palace built by Charles III. in 1738. P. produces much macaroni and a variety of ribbons, and has some coral and other fishing. Since 79 A.D. Vesuvius has poured its lava seven times over the town, which has been rebuilt as many times. Pop. (1874) 11,792.

Portico, in architecture, a range of columns in front of a building supporting a roof connected with the main edifice. It is called tetrastyle, hexastyle, octostyle, or decastyle, according as the columns number four, six, eight, or ten.

Portioners. See HEIRS-PORTIONERS.

Port Jack'son, an inlet on the coast of New S. Wales, forming one of the finest harbours in the world. It is 18 miles long, with an average width of three-quarters of a mile, and is deep, sheltered, and easy of access. The entrance, which is 2500 yards wide, is between two lofty perpendicular headlands.

That on the S. side is crowned by a lighthouse, whose light is visible for 25 miles. The scenery on the shores of P. J. is of the loveliest description. The N. shore is composed of rocky wooded hills, while on the S. shore stands the city of Sydney. Both sides are indented by a succession of beautiful little bays, and the lower half of the inlet is studded with rocky islands, on several of which, as well as on the mainland, batteries of heavy guns have been erected. P. J. is named after a sailor on board Cook's ship, by whom the entrance was first sighted on 5th May 1769. It was then supposed, however, to be a mere boat harbour, and its true character was not discovered till 1788, when Governor Phillip transferred to its shores the settlement mistakenly made at Botany Bay (q. v.).

Portland, Dukes of. See BENTINCK.

Portland, the largest city of Maine, U.S., is situated on a small peninsula of 1666 acres, jutting into Casco Bay. It is connected by rail with Boston, Montreal, and New York, and in 1876 a new railway was opened to the W. through the Notch of the White Mountains. P. is the winter port for the ocean steamers which run in connection with the Grand Trunk Railway at Montreal in summer, and ply between Liverpool and Glasgow. There are two steamers daily to New York, and daily boats to Boston. P. has two public libraries, several scientific societies, and 25 churches. On the 18th October 1877, a new Episcopalian cathedral was consecrated here. It measures 140 feet by 65 feet, and is built of blue stone, finished with Nova Scotia freestone. The value of the imports (molasses, fish, coal, salt, &c.) in 1876 was £2,812,639; of the exports (bacon, lumber, fresh and preserved meats, cheese, &c.), £4,108,298. In the same year there entered 405 vessels of 173,250 tons; and cleared 530 of 223,166 tons. P. supports three daily and nine weekly newspapers, and contains manufactories of locomotives and marine engines, carriages, furniture, &c. Pop. (1875) 35,031, or, with the immediate environs, about 50,000.

Portland Beds form the central group of the Upper or Portland Oolites, which is the highest British representative of the Oolitic or Jurassic Period. They lie between the Kimmeridge Clay below and the Purbeck Beds above, and consist in their lower portions of sands and sandstones, which, becoming calcareous, pass finally into limestone, which is sometimes Oolitic. This limestone is known as Portland Stone. These beds are well developed in Dorsetshire and Wiltshire, and can be traced as far N. as Oxfordshire and Buckinghamshire. Marine shells (lamellibranchs, gasteropods, &c.) and fish and reptilian remains occur as typical fossils.

Portland Cement. See MORTARS.

Portland, Isle of, a peninsula projecting from the Dorset coast into the English Channel, 4 miles S. of Weymouth by rail. It is connected with the mainland by the Chesil Beach, 10½ miles long and from 270 to 170 yards wide, a bank of siliceous pebbles loosely thrown together by the action of the sea, and gradually increasing in size as one proceeds from W. to E. P. itself is about 9 miles in circumference, being 4 miles long by 1½ miles broad. Area, 1408 acres; pop. (1871) 9907. Consisting of one solid mass of Oolitic limestone, P. is girt, except on the Weymouth side, by beetling cliffs, which terminate to the S. in P. Bill, with two lighthouses, 120 and 197 feet above the level of the sea. From the northern angle of the 'island' extends the P. breakwater, the two portions of which, with a respective length of 600 and 3000 yards, are separated by an opening of 400 feet. The first stone of this great work was laid by the Prince Consort, July 25, 1849; the last by the Prince of Wales, August 10, 1872; and its total cost, exclusive of convict labour, was £1,033,600. The artificial harbour formed by it is one of the largest in the world, having a sheltered anchorage of 6745 acres. Verne Hill (490 feet), the highest point of P., is crowned by Fort Victoria, with casemated barracks, garrisoned (1871) by 615 men, and surrounded by a dry ditch, to form which 1,500,000 tons of stone had to be blasted. Nature and art have combined to render P. second only to Gibraltar in strength; £400,000 having been expended on its fortifications up to 1875, and it has one great advantage over Gibraltar, that its batteries being all in the open air, the smoke clears off more readily than in rock-hewn galleries. P. prison (1848), consisting of eight blocks, is the largest in England, with (1871) 119 officials and

184

1508 convicts. These, like the 'islanders,' are chiefly employed in the Crown quarries, from which some 50,000 tons of 'P. Stone' (see P. BEDS) are annually exported. The 'P. sheep' are a small black-faced breed, whose flesh resembles Welsh mutton. There are two churches in the parish of P., and of its nine villages Castletown is the largest. Amongst the lions of the 'island' are Bow and Arrow Castle, a pentagonal tower, ascribed by tradition to William Rufus; Pennsylvania Castle, erected by a grandson of William Penn; and P. Castle (1520), formerly the residence of the governor, and converted into a Royal Engineers' depot since 1875. See Hutchins' *History of Dorsetshire* (3d ed. 1861-74).

Portland Sago. See ARUM.

Portland Vase, formerly known as the Barberini Vase, is a unique ancient Roman cinerary urn composed of two layers of glass, of a rich deep blue translucent ground, being decorated in relief with beautifully wrought white opaque figures, representing, it is believed, the marriage of Thetis and Peleus. It is round, 10 inches high and 7 in diameter, and has two handles. The P. V. was found in the 16th c. near Rome in a marble sarcophagus, supposed to be that of Alexander Severus, and for two centuries it was preserved in the Barberini Palace at Rome. It was purchased in 1770 by Sir William Hamilton, and subsequently it became the property of the Duchess of Portland at a price of 1800 guineas. In 1810, the Duke of Portland being one of the trustees of the British Museum, placed it in that institution for exhibition, where it remains, though not now exposed to public view. In 1845 a visitor maliciously dashed it to pieces, but it has since been skilfully repaired. A full description of the vase is given in *Archæologia* (vol. viii). Josiah Wedgwood, the potter, modelled the P. V. in jasper with white bas-reliefs. He made fifty copies of it, which were disposed of at fifty guineas each, and their value is now greatly enhanced.

Portland Vase.

Portlaw (Ir Gael, *Port-lagha*, 'the landing-place' or bank 'of the hill'), a town of Ireland, county of Waterford, on an affluent of the Suir, 6½ miles S.E. of Carnict-on-Suir. The town, formerly a mere village, took its rise on the introduction of the cotton industry by the Malcolmson family, whose cotton-mill still employs most of the inhabitants. Pop. (1871) 3143.

Port Louis, the capital of Mauritius, is situated on the N.W. coast of that island, hemmed in by rugged hills, and divided into three parts, inhabited by the whites, creoles, and Hindu Coolies (q. v.) respectively. The streets are straight, well kept, and usually lined with trees. Some of the public buildings are handsome, and there is a fine botanical garden. The harbour, which is fortified, is roomy, but difficult to enter, and unsafe in the hurricane season. The trade of P. L. is very extensive, and is nearly identical with that of Mauritius (q. v.). The climate is very hot, and the death-rate in 1876 was 35.1 per 1000, which was much higher than that for the island generally. Pop. (1871) 63,274.

Port Mahon (*Portus Magonis*), capital of the island of Minorca (q. v.), is a beautiful little town built in the form of an amphitheatre, and situated upon one of the finest harbours of the Mediterranean, which is defended by three forts. In 1873 the imports (leather, cotton, sugar) amounted to £49,283, and the exports (boots, cotton stuffs, wheat, and cattle) to £177,850. In the same year 385 vessels entered the port, with a total tonnage of 53,848. Pop. 12,800.

Porto Alegre, a town in the S.W. of Brazil, capital of the province of São Pedro do Rio Grande, at the N. end of the Lagoa dos Patos, on the right bank of the Guayba. It is the seat of a bishop, has a cathedral, a gymnasium, a hospital, good wharves, and regular steamboat communication with other ports in Brazil. Its imports in 1872 amounted to \$634,145; its exports to \$193,531. Pop. (1872) 25,000 (including 3000 Germans).

Portobello, a favourite watering-place on the S. side of the Firth of Forth, 3 miles E. of Edinburgh by the North British Railway. It is pleasantly situated in a level district, and has fashionable crescents and rows of elegant villas. A handsome marine parade stretches for a mile along the shore, and a fine iron pier, 1250 feet long, with a spacious saloon and band-stand at its far end, was erected (1870-71) at a cost of £11,000. The firm, gently sloping sands are covered by an animated crowd in summer. Among the best buildings are the town-hall (1863), the Free church, with a steeple 100 feet high (1876-77), and the School Board schools (1877). P. has also six other churches, several good hotels, a skating-rink, &c. There are extensive manufactures of earthenware, bricks, bottles, &c., and the railway station is the principal goods depot between Edinburgh and Newcastle. The first house built here was called P. from the circumstance that it was erected about the time (1739) of the seizure of Puerto Bello in Panama. Pop. with the adjoining village of Joppa (1871) 5481, increased in summer by not fewer than 8000 visitors. P., together with Leith and Musselburgh, sends one member to Parliament.

Porto Ferrajo, a seaport, on a beautiful bay enclosed by mountains, on the north coast of the island of Elba. It is strongly fortified with six batteries, and is a well-built town, though several of the streets are narrow. The Piazza d'Arme is the largest square. P. was the place of residence of Napoleon I. from May 5, 1814, to February 26, 1815. It has exports of sardines and tunny-fish. Pop. (1875) 5779.

Porto Maurizio, a town of N. Italy, capital of a province of the same name, 58 miles S.W. of Genoa. It stands on a bold headland, has a fine church and a good harbour, and carries on a large trade in olive oil, grain, &c. Pop. (1874) 7038.

Porto Novo (Parangpetta), a town in the district of S. Arcot, Madras Presidency, British India, at the mouth of the estuary of the Pellar on the Coromandel or E. coast, 116 miles S. of Madras, and 64 N.E. of Tanjore. Pop. (1871) 7182. It is celebrated for the battle won by the British, under Sir Eyre Coote, over Hyder Ali, on July 17, 1781. The result was the delivery of the Carnatic from the Madras invaders. A few years ago an extensive new landry establishment here with European capital; but though the establishment the enterprise did not prove a permanent success.

Portpatrick, a barony and watering-place in the county of Wigtown, Scotland, situated on the N. Channel, 8 miles from Stranraer by rail. It is the nearest point of Scotland to the Irish coast, being 2½ miles distant from Donaghadee. It was a mail-packet station for Ireland from 1602 till 1840, and in 1774 a quay was formed, with a reflecting light, 37 feet high. A new pier was built by Kenne at a cost of £160,000. A lighthouse was erected in 1832, which was, however, demolished by the Government in 1869. The harbour, though small, has (1878) a depth of 10 feet at low water of spring tides, and was formerly the scene of an active trade, chiefly in the exportation of fish, and the importation of Irish cattle and horses (20,400 cattle and 600 horses yearly about 1820). About half a mile to the S. is Dunskey Castle, an imposing ruin, on the brink of a precipice projecting into the sea. The Government works, on which during fifty years £250,000 had been expended, were abandoned in 1869. The town has recently been greatly increased by the erection of villas for summer visitors. Pop. (1871) 1488.

Port Phillip, an inlet on the S. coast of Victoria, measuring 30 miles from N. to S., and 35 miles from E. to W., with an area of 900 sq. miles. The entrance, which is easy of access, is 2 miles wide, and is fortified. The N. extremity of P. P. is called Hobson's Bay, and receives the river Yarra-Yarra (see MELBOURNE). On the W. side is another indentation, known as Corio Bay, on which is situated the town of Geelong (q. v.). P. P. was discovered by Acting-Lieutenant Murray, on 15th January 1802, and again, independently of him, by Flinders, on April 26th, in the same year. Murray named it Port King, after the Governor of New South Wales at that time, but the latter changed the name to P. P. in honour of the first governor. Till 1851, the district now forming the colony of Victoria was known by the name of P. P.

Portreeve (Lat. *portus*, 'a harbour,' and Old Eng. *gerefa*, an 'overseer'), in England formerly the chief magistrate of a seaport.

Portrush, a post town and seaport of Ireland, county of Antrim, stands at the extremity of a basaltic peninsula, nearly opposite the Skerries, 5 miles N. of Coleraine, and 50 N.N.W. of Belfast by rail. It is a seaport of Coleraine, and the terminus of a branch line of the Northern Counties Railway, has a good harbour and pier, and carries on some export trade. Lying only 6 miles S.W. of the Giant's Causeway, it is visited by great numbers of tourists, and is one of the places on the circular route of the North British Railway Company. Pop. (1871) 1106.

Port Said, a town in Egypt, at the Mediterranean entrance to the Suez Canal (q. v.). To this fact it owes its existence, which dates only from 1863. P. S. stands on a narrow strip of beach which divides the Mediterranean from the salt Lake Menzaleh, the ancient Gulf of Pelusius. Its harbour is artificial, and is divided into an inner and an outer anchorage, the former of which consists of a channel dredged between two stone piers, the western one being 7000 feet long. At the entrance to the inner harbour is a lighthouse 180 feet high, with an electric light. The chief trade of the port is in coal and stores for the use of steamers passing through the Canal. 260,000 tons of coal were imported in 1876. In the same year the number of vessels, not in transit through the Canal, which visited the port was 358, whose aggregate tonnage was 401,910. Of these vessels about two-thirds were British. P. S. has a very evil reputation for murders, robberies, and other crimes of violence, but since the lighting of the streets with gas in 1876 lawlessness has decreased. Pop. with Kantara (1872) 8671.

Port-Royal was the most celebrated of all monastic establishments. Two nunneries bore the name—one at Chevreuse, near Versailles, and the other in the capital, in the Faubourg de St. Jacques. The latter was called P.-R. de Paris, the former P.-R. des Champs, and is said to have dated from the time of Philippe-Auguste, who, having lost his way in the chase, found a shelter or *port* in the neighbourhood of Chevreuse. The nunnery was founded in 1204 by Mathilde de Garlande of the Montmorency family. The nuns were of the Order of St. Bernard of Cîteaux. In 1223 Honorius III. conferred on it the privilege of an asylum for seculars. The rules of St. Bernard were soon after departed from. The P.-R. gained notoriety first in the time of the great Jansenist leader, the Abbé de St. Cyran, who was father confessor to the nuns. The abbess, Marie Jacqueline Angélique Arnauld, with nearly the whole of her celebrated family, became devoted Port-Royalists. Under the management of the 'Mère Angélique' the establishment grew so rapidly that Madame Arnauld, mother of the abbess, purchased the large Hôtel de Clugny in the Faubourg de St. Jacques at Paris, whither her daughter removed in 1665. The house thus left deserted became the abode of a celebrated set of men known as 'Les Solitaires de P.-R.' Of these were Antoine Lemaître, nephew of Angélique, Claude Lancelot, Simon Séricourt, Isaac de Sacy, and Antoine Arnauld, Angélique's brother. Antoine, the great friend of Pascal and Nicole, was the indefatigable foe of the Jesuits, and gave Pascal the materials for the *Provincial Letters* (see ARNAULD). The life of these Port-Royalists was very austere; and because of their piety and their learning pupils flocked to them for instruction. For their school they prepared the celebrated P.-R. handbooks in grammar, classics, logic, geometry, &c. In 1664 the community was dispersed by force; in 1669 the P.-R. de Paris was reorganised under the Jesuits. The nuns in the P.-R. des Champs still refusing to subscribe the papal condemnation of Jansen, were dispersed in 1700 (many of them to suffer imprisonment in other convents), and their abbey was levelled to the ground. Many celebrated men have written the history of this interesting society. It may suffice to mention the *Mémoires* by Fontaine (1736); *Histoire Générale de l'Abbaye de P.-R.*, by Clémencet (Amst. 1755-57); *Histoire de P.-R.*, by Racine (Par. 1767); *Geschichte von P.-R.*, by Reuchlin (Hamb. 1839); *P.-R.*, by Saint-Beuve (5 vols. Par. 1840-60); *Mémoires of P.-R.*, by Schimmelpenninck (Lond. 1858); and *P.-R.*, by Beard (new ed. 2 vols. Lond. 1873).

Portsea Island, the peninsula on which are situated the towns Portsmouth and Portsea, lies in an inlet of the English Channel, and off the S. coast of Hampshire, a little to the E. of the Isle of Wight. It is bounded on the W. by Portsmouth Harbour, and on the E. by Langston Harbour, while on the N.

it is only separated from the mainland by a narrow channel, crossed by railway and passenger bridges. It is about 4 miles long, with an extreme breadth of $3\frac{1}{2}$ miles. On the W. it approaches to within 220 yards of the mainland promontory, and there this narrow entrance to Portsmouth Harbour is defended on the E. by Southsea Castle and on the W. by Monckton Fort. Langston Harbour is also entered by a narrow, strongly-defended channel, and on its W. side is Hayling Island, beyond which are Emsworth Channel and Chichester Harbour, separated by Thorney Island. The town of Portsea is included in the borough of Portsmouth.

Portsmouth, the principal naval arsenal of England, and an important seaport and borough in the county of Hampshire, is situated on the S.W. of the island of Portsea (q. v.), 26 miles S.E. of Southampton, and 75 S.W. of London by rail. It stands on the entrance to P. harbour. From the entrance to the harbour a sandbank called the Spit extends 3 miles S.E., having beyond it the splendid roadstead of the Spithead, where as many as 1000 ships of the line can anchor. Until within the last four or five years the town of P. was completely encircled by a belt of formidable fortifications, the approaches from Portsea town, Southsea, Landport, and the other suburbs being through four massive gateways. The town of Portsea was similarly fortified; but within the time mentioned the whole of the ramparts, bastions, embrasures, moats, drawbridges, and gateways, which gave the whole place the appearance of a huge and impregnable fortress, have been swept away, and the immense space thus created has been turned to excellent account by Her Majesty's War Department, under whose directions spacious recreation grounds have been constructed for the use of the officers and men of the army. Several wide and well-made roads have also been laid out, and various other improvements effected. The defences facing seaward now remaining, include the forts built at Spithead, while on the land side the dockyard and arsenal are protected by four forts on the heights of Portsdown and by the lines of Hilsa. P. is quadrangular in shape, and covers 1100 acres. Most of its streets are mean and narrow, much inferior to those of Portsea, which has several handsome terraces, and one fine square called St. George's. Southsea is the fashionable district of the borough. It has a fine esplanade and pier. Though it sprang into existence almost entirely during the last half-century, it is now the largest, and is rapidly becoming the most popular, watering-place in the S. of England. To the E. of Southsea, distant about a mile, are the headquarters of the Royal Marine Artillery at Eastney. It is a gigantic establishment, and is looked upon by military critics as a perfect model of completeness. Great improvements have been carried out in P. of late years, £160,000 having been spent on drainage alone, while the Victoria Park was opened 24th May 1878. The parish church of St. Thomas A'Becket, in the Early English style, was founded by Richard Toelove, Bishop of Winchester, 1173-1189. Only a portion of the original structure now remains, the additions being of various later periods. In the chancel is a monument, with an urn, to George Villiers, Duke of Buckingham (q. v.), Lord High Admiral, who was assassinated at his residence (which still exists) in the High Street by John Felton in 1628. The next church in importance is the Royal Garrison Church, formerly called the church of Domus Dei, in the Early English style, founded in 1210, and lately restored at a cost of £5000. Other buildings are the Royal Naval Club, the Seamen and Marines' Orphan School, the townhall, theatre, custom-house, the Cambridge Barracks, Colewort Barracks, Clarence Barracks, and Artillery Barracks, Railway Station, the Gas Company's offices, and the excellent new hotels at Southsea. Portsea town is celebrated as the locality of P. dockyard, which is entered through a gateway situated at the end of the famous Common Hard. The old dockyard contains upwards of 115 acres, upon which are erected gigantic foundries, workshops, storehouses, &c. It also contains several spacious docks, together with a steam and repairing basin. During the past few years the dockyard has been extended to the N.E., the ground necessary for such extension having been mainly reclaimed from the mudlands of the harbour, the area of the extension ground alone being 178 acres. There are six basins, each capable of floating the largest ship ever yet built or likely to be built; and in order to convey some idea of the vast character of the works, it may be stated that the basins alone cover 70 acres. The cost has been upwards of £2,250,000. The

docks are unsurpassable; the whole of the bricks (many millions in number) required for the construction of the massive walls of the basins, together with the numberless erections all over the works, were manufactured by convict labour, with the aid of powerful steam-machinery, from clay excavated on the ground. The erection of permanent storehouses, workshops, &c., has not yet (1878) been proceeded with. There is no naval establishment in the world in any way approaching this in general extent. Between Portsea town and P. stands the Gun Wharf, a very large depot for all descriptions of ordnance and war material. There are two armouries in this establishment, containing together about 40,000 stand of arms, arranged somewhat after the plan of those in the Tower of London. In the wood mills are several machines invented by Brunel, capable, with the aid of four workmen, of making annually 150,000 blocks. The entrance to the docks is 80 feet wide, and 27 feet deep at low water. The shipbuilding slips cover 15 acres, and the 'steam-basin,' for the repair of ships' machinery, is 900 feet by 400, and has 26 feet of water at spring tide. The trade of P. is chiefly dependent on its dockyard. It has, however, extensive breweries; while coals, corn, cattle, and sheep are imported. In 1876 there entered the harbour 1947 vessels of 190,958 tons, and cleared 1172 of 54,849 tons. The gross amount of customs revenue received in the same year amounted to £25,770, and the total value of imports of foreign and colonial merchandise was £343,173. In 1877, 311 vessels of 20,170 tons belonged to the port, besides 189 fishing-boats. P. has a constituency of 15,409, and returns two members to Parliament. Pop. (1871) 112,954; estimated pop. (1878) 129,461. P. was a naval station in the reign of King John. Burned by the French in the reign of Richard II., it was fortified by Edward IV. and Henry VIII., being already, in the reign of the latter, the chief station of the English fleet. Its defences were greatly extended under Charles II., William III., and George III., and are now believed to be impregnable.

Portsmouth (1), a city of Ohio, U.S., situated at the confluence of Scioto River with the Ohio, and at the S. terminus of the Ohio and Erie Canal, is the place of export for the mineral regions of Ohio and Kentucky. It has twelve churches, an opera-house, six banks, three foundries, besides numerous factories, and three newspapers. Pop. (1870) 10,592.—P. (2), a city and port of Virginia, on the E. bank of the Elizabeth River, opposite Norfolk (q. v.), with which it is connected by ferry, has one of the best harbours in the United States, and is the seat of a navy-yard, dry-dock, and naval hospital. Lines of steamers sail from here to the principal Atlantic seaports. P. contains thirteen churches, a court-house, scientific academy, and a daily newspaper. The exports include cotton, oak staves, naval stores, and pig iron. Pop. (1870) 10,402.—P. (3), a city and port of entry of New Hampshire, U.S., lies on the right bank of the Piscataqua River, $3\frac{1}{2}$ miles from the Atlantic. It contains two libraries of about 14,000 vols., ten churches, two breweries, several weaving establishments, two daily and two weekly newspapers. The United States Navy-Yard, situated about half a mile distant, is built upon two islands lying on the Kittery side of the river, and comprises 170 acres. P. is the only seaport of New Hampshire. Its harbour is one of the best in the United States, having a depth of 40 feet at the entrance at low tide, and never freezing. Shipbuilding is the chief industry, and many celebrated war-vessels have been constructed here. The first settlement was made by the English in 1623. Pop. (1870) 9211.

Portugal, the most westerly European kingdom, is physically one with Spain, occupying the Atlantic margin of the Iberian peninsula, in lat. $36^{\circ} 57' - 42^{\circ} 8'$, and long. $6^{\circ} 12' - 9^{\circ} 32'$. It is surrounded on the N. and E. by Spain, and on the W. and S. by the Atlantic, and, with an average breadth of only 100 miles, it has a length from N. to S. of 370 miles. The coast, 500 miles long (100 miles facing the S.), is little indented, and is for the most part flat and either marshy or sandy; but in some places, as between the capes Roca and Mondego, it rises in a bold rugged line of cliffs. The chief headlands are Cape Carboeyra, Capes Roca and Espichel, on either side of the Tagus estuary, Cape de São Vicente, forming the S.W. angle of P., and in the extreme S. Cape de Santa Maria. Nearly all the harbours have bars, and with a breeze from the sea a terrible surf breaks along the whole

coast-line. The following table is from the *Annuário Estatístico do Reino de P.* (Lisbon, 1877):—

Provinces.	Area in sq. miles.	Pop. (1875).	Chief Towns.
Minho, Entre Douro e, Traz-os-Montes, Beira (Alta and Baixa), Estremadura, Alemtejo, Algarve,	3094 3999 8586 6873 9982 2730	967,578 372,349 1,314,684 855,351 345,394 194,754	Oporto. Bragança. Coimbra. Lisboa. Evora. Faro.
	35,264	4,047,110	

Physical Aspect.—The surface of P. is in great part mountainous, the scenery combining highland grandeur of form with the bright subtle colours of a southern clime. Many irregular offsets of the Cantabrian range enter the northern provinces, and one of these, the Serra de Alcoba, taking a S. and then a W. direction, extends through Beira, and terminates in Cape Mondego. (The Portuguese *serra*, Sp. *sierra*, is not the Lat. *serra*, 'a saw,' as is commonly supposed, but the Arabic *sehrah*, the same as sahara, meaning 'uncultivated tract.') Another range of greater elevation and extent traverses Beira and Estremadura, and ends near Lisbon in the Cabo de la Roca. It bears in Beira the name of Serra de Estrella, and in Estremadura receives several names, the main range being called the Serra de Junto. The Serra de Estrella is the highest range in P., having an elevation of 7524 feet. As the range approaches the sea, it forms a series of ridges, running E. and W., and occupying the whole space between the coast and the Tagus to 30 miles N. of Lisbon. Behind Lisbon rises Cintra, the summer retreat of the wealthy Portuguese and of the English residents. To the N. of Cintra stretches the broken hilly plateau across which Wellington drew the famous lines of *Torres Vedras*, that saved Lisbon from the French in 1810. In the S., a range known partly as the Serra de Caldeirão, and partly as the Serra de Monchique, crosses from E. to W., and separates Algarve from Alemtejo, terminating in the Cape de S. Vincente. It is a continuation of the Spanish Sierra Morena, from which it is separated only by the narrow valley of the Guadiana. Of the valleys the largest is the basin of the Mondego, between the Serra de Alcoba and Serra de Estrella. Fine valleys of lesser extent are those of the Lima and Cavado in Entre Douro e Minho, and the upper course of the Vouga in Beira. The most extensive plain in P. is the Campo de Ourique, in Alemtejo. All the great rivers of P., the Douro, Tagus, and Guadiana, have a Spanish source. In the extreme N. the Minho (q. v.) separates the province Entre Douro e Minho from Pontevedra in Galicia. The Douro (q. v.) first forms part of the Spanish frontier line, and then the boundary between the two most northerly provinces and the province of Beira. In P. the Tagus (q. v.) has a course first due W. and then S.W., and before reaching Lisbon expands into a magnificent and nearly land-locked harbour. Along its banks, from Lisbon to Abrantes, where navigation ceases, there is a succession of luxuriant gardens and vineyards. Entering from Spain near Badajoz, the Guadiana (q. v.) flows in a southerly direction, partly in P. and partly on the boundary. The Mondego (in Beira), the largest purely Portuguese river, although only 100 miles long, is subject to terrible inundations. The rivers, indeed, are all liable to flooding, and the freshets on the Douro have been known to raise the level of the water at Oporto 20 or even 30 feet in six hours. Of the minor rivers, the chief are the deep and rapid Lezere, which joins the Tagus below Abrantes, and the Sado or Sado which waters the Campo de Ourique. Near Aveiro in Beira, and in the vicinity of Setuval, are extensive salt-marshes.

Geology and Climate.—The base of the mountain chains is formed of granite and other eruptive rocks. Granite appears in the lofty peaks of the Serras de Estrella and Monchique, and the town of Oporto stands on a mass of this rock some five miles wide. Further to the E. syenite takes the place of granite. The flanks of the Serra de Estrella are covered with strata of clay-slates and mica-schists. Clay-slates overlie the whole district of the upper Douro, where all the fine port wine is produced, the line of junction with the granite marking the limits within which are cultivated the finer qualities of the wine. About 12 miles E. of Oporto and near Volongo, a hard, dark-coloured slate of the finest quality is quarried extensively. In the same locality several beds of anthracite have been long wrought at various

points for the market of Oporto. Throughout P. there is great diversity of climate, but the dry, oppressive heats of Central Spain are unknown. Atlantic rains abundantly fertilise the country, especially from October to April. The mean temperature at Lisbon is 61° F. Snow falls heavily on the mountains of the two northern provinces, but in the S. winter is seldom accompanied by snow, and the summers are hot and long. In the lowlands of the S. spring begins in January and harvest is over by midsummer.

Soil and Productions.—The soil is in great part highly productive, but agriculture is still conducted in a manner at once indolent and primitive. The lowlands produce rice, and in the more elevated districts are cultivated wheat, barley, oats, maize, hemp, and flax. Fruits are exported, the central and southern provinces producing abundantly oranges, lemons, figs, almonds, &c. The staple product of P. is the celebrated rich, red, port wine, so called from being shipped at Oporto. Next to it comes the olive, which is grown extensively in the S., but the oil is not of the finest quality. The oak prevails among the trees of the N., the chestnut among those of the centre, and among those of the S. the cork, date, and American aloe. In the two northern provinces are reared the finest cattle, while Beira is noted for its horses, and Alemtejo for its sheep. Oxen are employed for draught, and the beasts of burden are chiefly asses and mules. In the highlands are reared large herds of goats and swine. The rivers abound with fish, and the southern province of Algarve has extensive fisheries of pilchards, tunny, and anchovy. The mineral wealth of P. is considerable, but there is little mining enterprise. Salt, the only mineral exported, is evaporated largely in the coast marshes, and is specially prized in England in ship victualling, for which use it is peculiarly fitted by its superior hardness.

Industries, Commerce, &c.—The chief, almost the only, industrial centres, are Lisbon and Oporto, and in both places trade predominates greatly over manufacture. The industrial products of P. are mainly gold and silver ware, silks, woollens, cottons, linens, pottery, tobacco, gloves, paper, and chemicals. P. has not a single canal, and it is only in the present century that a carriage-road has been completed between Lisbon and Oporto. Now, however, railways connect the principal towns, and in 1877 the total length of lines completed throughout P. was 1559 miles. In 1874 the exports—wine, oil, cork, oranges, lemons, pyrites, and wool—amounted to £5,250,000, and the imports—textiles, yarn, metals, leather, cattle, cereals, and colonial produce—to £6,494,000. In 1877 as much as 7,721,028 gallons of port wine were shipped to England from Oporto, the greatest quantity exported since 1801. England receives some seven-elevenths of all exported wine. The cotton goods imported from Great Britain in 1876 amounted to £940,191, woollen fabrics to £152,644, wrought and unwrought iron to £245,269. The value of the total exports to Great Britain (1876) was £3,361,071, and of the imports thence, £2,231,191.

Government, Law, and Finance.—The government is a constitutional monarchy, hereditary in both male and female lines, and is based on the *Carta de Ley* of 1826. The *Cortes Geraes*, or representative assembly, consists of a chamber of peers and a chamber of deputies. The *Camara dos Pares* is composed of about 100 members, nominated by the king for life. The *Camara dos Deputados* is popularly elected, and comprised 108 members in 1869. The king is aided by a cabinet of five ministers, and by a council of eleven members chosen for life. The deputies (elected directly by all citizens with an income of £22) must have an income of £89, unless they belong to any of the learned professions, in which case all such conditions are set aside. The *Titulados* are the titled classes, or higher nobility. On account of the poverty of a great number of the *Fidalgos* or provincial aristocracy, a law was passed in 1864 by which transmission of the dignity became dependent on an academical degree and an income of £500. There are 110 courts of justice, five courts of appeal (*Relações*), and a supreme court at Lisbon. The *Alfonsine Code* of the 5th c., and the code of Philip IV. of Spain (*Código Filippino*), are still in use, except in commercial cases. Trial by jury is adopted in some suits. In 1877-78 the budget gives the national income at 25,262,124 milreis (1 milreis = 4s. 7d.), and the expenditure at 26,424,685 milreis. The public debt amounted to £79,061,780 on the 30th June 1876. A budget without a deficit has been unknown in P. for nearly half-a-century. The debt, which includes foreign loans to the amount of £30,188,700, bore £2,250,768 of interest in the financial year 1875-76. The budget of the colonies (not in-

cluded in the above) gave the receipts at 2,027,154 milreis, and the expenditure at 1,930,164 in 1875-76.

Army and Navy.—The fundamental military law of 1864 was supplemented by an act of 26th April 1877. The army is raised partly by conscription, and the period of service is eight years, of which three are in reserve. On August 31, 1877, the effective army comprised 1671 officers and 34,062 men, and 4210 horses and mules. It can be raised on a war footing to 74,141 men and 2649 officers. In 1875 an army of the colonies (*do ultramar*) was 7845 strong. The fleet in 1877 comprised 27 steamers of 4255 horse-power, with 144 guns; and 12 sailing vessels with 36 guns. The largest vessel, the *Vasca da Gama*, was launched on the Thames in 1876, and is a 'ramming' corvette of 450 horse-power, clad in 10-inch armour, and carrying two 18-ton guns. The coast and frontier are guarded by 55 fortresses, most of which, however, are mere castles.

Religion and Education.—The religion of P. is Roman Catholicism, and the Church is governed by the Cardinal Patriarch of Lisbon, the Archbishop of Braga (primate of the kingdom), the Archbishop of Evora, and 14 bishops. Some 18,000 clergy hold cures. The convents were suppressed in 1834, and the revenues and buildings were appropriated by the State. The property confiscated comprised 632 monasteries, 118 nunneries, and an annual revenue of nearly a million sterling, which was applied to the national debt. There are Protestant chapels in Lisbon and Oporto. Education, which is in a very backward state, has been recently receiving the earnest attention of the State. The system, as reorganised in 1836, was modified by a law of 1875. There are now two classes of elementary schools, only one class being free. In 1869 there were 2359 elementary schools, with 117,305 pupils on the rolls, but of these only 62,937 were in attendance. In 1869 the Lyceums or secondary schools, 21 in number, had 3744 pupils. There are 6 normal schools (one for females), 19 theological seminaries, 3 medico-surgical schools, 2 fine-art academies, a music conservatoire, a military college, &c. The only university, one of the oldest in Europe, was originally founded at Lisbon in 1290, and was finally transferred to Coimbra in 1537. It has 46 professors and some 900 students. Education is controlled by a supreme council, which has as president the Minister of the Interior, and as vice-president the Rector of the University. The grant for education was 870,683 milreis in 1878.

Ethnology.—The Portuguese are mainly the descendants of the ancient Celtic inhabitants of Iberia. Thick-set and light-complexioned, they differ no less in appearance than in language from the swart, stately Spaniard, whom they resemble so closely in the love of ceremony and display, in dignified suavity of manner, and confirmed indolence of life. As a rule, the people, urban as well as rural, are dirty, ignorant, and superstitious, but the peasants of the uplands are distinguished by superior vigour and self-reliance. In the S. a large infusion of Arab blood shows itself in the tall, little figure, and dusky, well-cut face. Music is the only fine art in which excellence is attained by the Portuguese.

Colonies.—The foreign possessions, according to the *Diário* for 1877, had an estimated area of 709,469 sq. miles, and a pop. of 3,201,833. In *Africa* these include the Cape Verde Islands, Bissão, Cacho, and Bolama (in Senegambia), Princes and St. Thomas Islands, Lower Guinea (from Loango to Benguela), Mozambique, Sofala, &c.; in *Asia*, Goa, Salcete, Bardez, Damão, Din, Timor, and Cambing (Indian Archipelago), and Macao in China. In terms of a law of 1858, domestic slavery ceased in the colonies on 29th April 1878.

History.—The name P. is a corrupted form of that of the hill fort, *Portus Cale* (*Portugale*), which stood on the S. bank of the Douro, and is now one of the suburbs of Oporto ('the harbour'). A place of thriving trade before the invasion of the Romans, who named it *Portus*, 'the harbour' was the key of the Christian position during the long occupation of the south by the Moors. Limited at first to the lower basin of the Douro, the name P. was gradually extended as the country was recovered from the Infidels. A sketch of the ancient inhabitants of the peninsula is given in the article HISPANIA. The Carthaginians under Hamilcar subdued the region, and were followed by the Romans. Under Augustus the peninsula was divided into the three provinces Bética, Tarraconensis, and Lusitania, the last comprising great part of modern P., and parts of Leon and Spanish Estremadura. In the 5th c. A.D. Lusitania, like the rest of the peninsula, was overrun by the Visigoths, and in the

8th c. was conquered by the Arabs. The resistless tide of Moslem invasion broke on reaching the precipitous Asturian mountains, and a remnant of the Christian Visigoths, who had retreated to the highland recesses, maintained perfect independence throughout the long period of Moorish dominion, and founded the Christian kingdoms of N. Spain. The warlike Fernando, king of Leon and Castile, in the course of marauding expeditions conquered and occupied the important city and stronghold of Coimbra in 1064. His son Alonso IV. seized his brother's territory of Galicia, which included part of the N. of P. Meanwhile the long wars were attracting to the Christian courts and camps of Spain the flower of European chivalry. Two knights of the house of Burgundy, Counts Raymond and Henri, acquired the highest favour with Alonso. Count Raymond received with the hand of the king's daughter the government of Galicia and P.; but after a terrible defeat near Lisbon in 1095, he was deemed too weak to hold the outlying vicereignty, which was given to Count Henri, the husband of Alonso's natural daughter. Henri was made governor of the whole district between Minho and Tagus, and died in 1114. His queen, Tracaja, subsequently alienated the nobles by the favours showered on her paramour, Fernando Perez, and was displaced by her son, Alfonso Henrique, a young prince of singular skill, valour, and energy. Alfonso I. defeated a large Saracen army in the plain of Ourique, Alentejo, in 1139, took the great stronghold of Santarem, and with the aid of a fleet of English, N. German, and Flemish crusaders, carried Lisbon itself by siege in 1147. The restless warrior, crowned almost at every step by victory, was recognised as an independent sovereign by Pope Lucius II. in 1144, and his deeds thrilled with admiration every court in Europe. Before his death, in 1185, he had kindled the fire of patriotic loyalty in the nation, which his sword had extended to the Mediterranean Sea. The Burgundian dynasty founded by him continued to rule P. till 1580. The war with the Infidels was continued by Alfonso's immediate successors, and Alfonso III. (died 1279) was called the Restorer, on account of his reconquest of Algarve. His son Dinis, the founder of the university at Lisbon (1290) and a liberal patron of learning, laid the foundation of the commercial greatness of P. in the next century. The following reign, that of Alfonso IV. (1325-57), was taken up mainly with Castilian and Moslem wars. Pedro I., son of Alfonso, is chiefly remembered for his secret marriage with Ines de Castro, which led to such a tissue of crimes. With Fernando I., whose whole reign was a struggle for the Castilian crown, the direct male Burgundian line became extinct in 1383. His daughter, the wife of Juan I. of Castile, was excluded, though lawful heiress, on account of the aversion of the Portuguese to a connection with Castile, and the states proclaimed a natural son of Pedro I., Dom João, king in 1385. João wisely reformed the administration, transferred the royal residence from Coimbra to Lisbon, and inaugurated the enterprises of foreign conquest and discovery, which shortly raised P. over all the maritime powers of Europe. But to his third son, Henrique the Navigator (q. v.), is P. chiefly indebted for this suddenly acquired pre-eminence. Stirred from boyhood with an enthusiasm for geography, he gathered together voyagers and men of science, and sent forth the various expeditions which explored the W. coast of Africa, and discovered the Azores, Madeiras, Canaries, Cape Verde, and other islands. The prince bore the expense of these expeditions till a national interest was awakened in the W. African trade. Maritime discovery and colonisation continued during the reign of Alfonso V. (died 1481), and culminated during that of João II., one of the ablest of Portuguese monarchs. In 1486-87 Bartholomeo Diaz doubled the Cape of Good Hope, and sailed along the Kafir coast as far as the Great Fish River in two small vessels fitted out by João. In 1495 Manoel succeeded João, and in his reign Vasco da Gama (q. v.) made his famous voyage to India, and Cabral discovered Brazil (1500). The great navigator Magalhães, though he entered the service of Karl V., was a Portuguese. The cradle of discovery and home of commerce, P. at this period attained its greatest intellectual eminence. Its plate and goldsmith's work had great artistic value, its Burgundian Gothic style in architecture was noted for nobility of proportion and richness of tracery, and, above all, its glory had been sung in the *Lusads* of Camoens. When João III. ascended the throne in 1521, P. was one of the first kingdoms in Europe, and Lisbon one of the wealthiest cities; but in 1536 the Inquisition was put

in force against the Jews, and this was followed by the first admission of the Jesuits. The expulsion of the rich enterprising Jews was a deadly blow to industrial prosperity, but the rapid decline of the nation was due in a greater degree to the bigotry and ambition of the Jesuits. Under their influence João's grandson Sebastian, a youth of fourteen years, started on a Quixotic expedition to Africa against the Infidels, which ended in the defeat of the Portuguese and the loss of their king at Alcazar in 1578. Cardinal Henrique, Sebastian's uncle, reigned only till 1580, and his death marks the extinction of the old Burgundian line. The nation clung to the hope that Sebastian was still alive in the hands of the Infidels and would return, but meantime numerous aspirants were struggling for the throne, and eventually Philip II. of Spain annexed P. to his own dominions. P. was now worse ruled than ever, and was burdened with much of the expense and misery of the Spanish wars in Germany and the Netherlands. Moreover, as a penalty of its identification with Spain, it lost to the Dutch great part of its foreign possessions. But at last, after a shameful union of 60 years, P. regained its liberty by a conspiracy which placed João de Bragança, a descendant of the royal family, on the throne in 1640. After a war which lasted till 1668, Spain ceded all claims to P. by the treaty of Lisbon. The Dutch also restored Brazil to the Portuguese, and in 1683 a commercial alliance was entered into with England; but nothing could bring back to P. her old prosperity. In the reign of José I., the minister Pombal (q. v.) effected certain reforms and procured the expulsion of the Jesuits in 1759. But P. lapsed into mal-administration during the reign of Maria Isabella (1777-89). In the war between France and Spain, João VI. was ordered by Napoleon to seize the British merchandise in P., and on his refusal was declared to have forfeited the throne. He solicited the protection of England, and, setting sail with his family, transferred the seat of government to Rio Janeiro in 1807. The French occupied P., but were forced to withdraw on their defeat at Vimiera by the English and Portuguese allies, under Sir Arthur Wellesley, in 1808. Wellington's defence of the triple lines of Torres Vedras against Marshal Massena (1810) completed the deliverance of P. from Napoleon's tyranny. João continuing to reside in Brazil, a revolution took place at Lisbon in 1820, when without bloodshed a constitution was proclaimed in place of the old absolute monarchy. In 1821 João returned, but was not allowed to land till he had ratified the acts of the Cortes. Adopting a liberal policy, he accepted the constitution, and in 1825 acknowledged the independence of Brazil, under his brother Dom Pedro, retaining himself merely the imperial title. João was succeeded in 1826 by Pedro IV. (q. v.), who organised the state and then abdicated in favour of his daughter, Dofia Maria da Gloria. In 1828 Miguel (q. v.) the 'absolutist,' uncle of Dofia Maria, usurped the throne, and plunged P. into three years of anarchy. In February 1832 Dom Pedro landed with a strong force (partly English), and, after a feeble resistance, Miguel capitulated, and was allowed to leave the country. Pedro died in 1834, and Dofia Maria, who had assumed royal authority, married Prince Ferdinand of Saxe-Coburg in 1836. The disorders of her reign were checked, but only for a time, by the armed intervention of the great powers in 1847. As a result of one of many insurrections, the Marquis de Saldanha, grandson of Pombal (died in London 21st November, 1876), was appointed minister, but the popular hero succumbed to court influence. Maria died in 1852 and her son ascended the throne as Pedro V. On the death of the latter in 1861 his brother became king as Luis I. Under constitutional government, P. remains tranquil and prosperous. In recent years, P. has taken honourable part in the work of African exploration. See the historical works of Fortia D'Orbay and Mielle (10 vols. 1828-29), Schäfer (5 vols. 1836-54), Rebello da Silva (for 17th and 18th centuries, 3 vols. 1860-67), Bollaert (19th c., 1870), and Diniz (6 vols. 1871); also Lavaigne, *L'Espagne et le P.* (Paris, 1867), and Latouche, *Travels in P.* (London, 1875).

Portuguese Language and Literature. Portuguese, one of the six literary descendants of the *Lingua Romana Rustica*—the so-called Romance Languages (q. v.)—claims for itself seniority in the group, and boasts the title of the 'eldest daughter of Latin.' It is, however, only saved from ranking as a dialect of Castilian, with which its vocabulary is almost identical, and of which it has been described as a weakened and contracted

form, by the possession of certain grammatical peculiarities, the most marked of which, its power of affixing personal endings to the infinitive (*ter, ter-es, ter; ter-mos, ter-des, ter-em*), appears in the oldest monuments of the language. Its seemingly archaic superlative, on the other hand, was a restoration of Sá de Miranda in the 16th c.; and similarly the large admixture of French words, which has misled Sayce into saying that 'Portuguese is more closely related to French than the intervening Spanish,' may be ascribed to the numerous retinue of Henrique of Burgundy, the founder of the monarchy. Though far less mixed than Castilian with Oriental elements, Portuguese, according to Sousa's *Vestigios da Lingua Arabica em Portugal* (Lisb. 1789), contains no less than 270 Arabic and Persian words. Some of these, however, Diez refers to a Latin or Teutonic origin (e.g., *camisa*, 'shirt'), and the remainder all denote either sensible objects or scientific ideas, with the single exception of the interjection *oxalá*, 'would to God,' from the Ar. *inshá Alláh*. So that it seems that the relations of Islam to Christianity were limited to outward communication, and permitted none of the closer intercourse that had existed between Goths and Romans. Among the distinguishing features of Portuguese are its retention of the Latin *f*, as in *filho* (Sp. *hijo*) from *filius*; its elimination of middle consonants, as *dôr* from *dolor*, and *pai* from *pater*, a process also at work in French; its assimilation of *l* to the succeeding consonants, as *Afonso* for *Alfonso*, or change of it to *r*, as *frasco* for *flasco*; its rejection of the gutturals and harsh aspirants of Spanish, and possession of five nasal vowels (approximately pronounced *ang, eng, ing, ung, oong*) and of five double consonants, *ch, lh, nh, ph, and rr*. Bearing these differences in mind, a student who is familiar with Spanish will find but little difficulty in deciphering the meaning of Portuguese, as may be seen by comparing the Spanish version of Luke xv. 12, 'Padre, dame la parte de la hacienda que me toca. Y él repartió la hacienda,' with the Portuguese, 'Pai, dá-me a parte da fazenda qua me toca. E elle repartio a fazenda.' Portuguese is spoken, with certain dialectic modifications, in Brazil and parts of the E. Indies and Western Africa; whilst of its home dialects the most strongly marked are those of Beira and Minho. There are English-Portuguese grammars by Vieira (13th ed. Lond. 1869), J. D. D'Orsey (Lond. 1868), and A. Elwes (Lond. 1877), and dictionaries by J. de Lacerda (2 vols. Lisb. 1871) and Vieira (Paris, 1873). The first part of a dictionary, embracing the dialects of Brazil, Cape Verde, &c., and to be concluded in 3 vols., was published at Lisbon by the Academia Portugueza on 1st January 1878. See Diez, *Grammatik der Romanischen Sprachen* (3d ed. 3 vols. Bonn, 1870-71).

Throughout the whole course of its history Portuguese literature has of necessity been closely associated with that of Spain. Portuguese poets have written in Castilian, and Spanish poets more rarely in Portuguese, whilst for nearly a century the language of the greater seemed likely wholly to supplant that of the smaller country. Nevertheless Portuguese writers have been strongly affected by other than Spanish influences, and have successively taken for their models the literatures of Provence, of Italy, of France, England, and modern Europe generally. That a native ballad poetry existed prior to the coming of Henrique of Burgundy is probable, though all traces of such have long since disappeared. He, fresh from the land of the Troubadours, brought with him their courtly and artificial poetry, before which the homely utterances of the people would soon be hushed; and the earliest monuments of Portuguese literature that have come down to us are the *Cancioneiros* or song-books, composed in the Gallican dialect, but plainly formed on a Provençal pattern. Of these, the most ancient is the *Cancioneiro d'el rei Dom Diniz* (circa 1300, latest ed. 1878). To a somewhat later period belongs the *Amadis de Gaul* (q. v.) of the Portuguese Lobeira, which, if really written in its author's native speech, is the first known prose composition in Portuguese, and also one of the few works that are famous beyond the Lusitanian frontier. During the 14th and 15th centuries the muse of Portugal continued to dwell in courts, enjoying the patronage of Afonso IV. and his half brother Pedro, the reputed author of the *Cancioneiro do Real Collegio dos Nobres* (ed. by Varnhagen, Madr. 1849), and after them of the two Joãos. From the scanty remains of Maucias el Enamorado (circa 1425), and from Resende's *Cancioneiro Geral* (edited by Kausler, 3 vols. Stuttg. 1846-52), it seems that trifling lyrics and brief didactic pieces formed the staple productions of this age, its chroniclers—Lopez, Azurara,

Pina, &c.—being few and far between. The epochs of Portugal's political and literary glory were identical. As the age of the great English navigators was also the age of Shakespeare and Ben Jonson, so Da Gama and Magalhaens were contemporaries of Bernardin Ribeyro, who restored the eclogue to modern poetry and wrote prose romances, half pastoral, half chivalrous, entitled *Menina e Moça*; of Sá de Miranda (1495-1558), author of sonnets, pastorals, poetical epistles, and a couple of 'erudite' comedies; and of Antonio Ferreira (q. v.), whose tragedy, *Inez de Castro*, was only preceded by the Italian Trissino's *Sofonisba*. These, with Caminha, Bernardes, and Cortereal, formed the Coimbra school of courtly poetry, and drawing their inspiration from the Italian writers of the Renaissance, had little influence on the national mind. From the nation's self arose the greatest poets—Camoens (q. v.), of whose *Lusads* an English verse translation by Aubertin, more faithful than Meikle's, has just been published with the text (2 vols. Lond. 1878); and Gil Vicente (q. v.), the model of Calderon and Lope de Vega, to read whose *autos* and *farsas* Erasmus is said to have mastered Portuguese. Had he known their contents, he would perhaps have spared his pains, for with their grotesque jumble of Venus and the Virgin, St. Peter and Bacchus, they can hardly but strike the foreign reader as ridiculous. To the first half of the 16th c. also belongs the best historian—João de Barros (q. v.). The field of Alcazar (1578) proved fatal alike to Portuguese arms and literature. Thenceforth the cobbler Bandarra might vainly prophesy the resurrection of his country's greatness, or Brandom in his *Elegiada* (1588) mourn over its decay, but most of their fellow-poets either wrote in Spanish, or gave themselves up to slavish imitation of the Cordovan Gongora (q. v.) with his eternal loves of Polyphemus; and the only national productions were Castellobranco's pedantic *Afonso Africano* (1611), the pastorals of Oriente, Lobo, and Tagarro, a few *autos* and *entremeses*, and the sermons of the great Jesuit missionary Vieira (1608-97), published at Lisbon (15 vols. 1748). Even after the revival of political liberty Spanish plays continued to rule the Portuguese stage, and the works of Sousa (see FARIA Y SOUSA), Bacella, Bahia, and the nun Violante do Ceo are stuffed with that 'Gongorism' which Andrade alone had wit and courage enough to satirise. The adoption of French Classicism as a new standard of taste was inaugurated by the foundation of the Academia Portuguesa (1741), and by Ercygra's *Henriqueta* (1740), a wearisome epic based on Boileau's style, in which its author sought, but failed, to combine the beauties of Homer, Virgil, Lucan, Ariosto, and Tasso. Down to the present century, Gallomania continued to be fostered by the Portuguese Arcadia, a literary coterie comprising Garção, Diniz, the barber Quita, the lyricist Nascimento (1734-1819), and Manoel de Bocage (1771-1805), the mannerisms and extravagances of whose idylls, sonnets, and epigrams are redeemed by fiery patriotism and passionate earnestness. By the Peninsular War Portugal was brought into close contact with England, and through translations became acquainted with several of our leading writers; and Scott and Byron have exercised an unmistakable influence over many of her later poets and novelists. The best known of these are the dramatist Almeida-Garrett (1799-1834), a complete edition of whose works appeared at Lisbon (16 vols. 1854-55); Alexandre Herculano (1810-77), author of religious and political poems, and of an able *História de Portugal* (4 vols. Lisbon. 1851); the lyricist and romance writer Palmeirim (born 1825), and Ferreira, whose epic *D. Jayme* (Lisb. 1862) ranks high in the estimation of his countrymen. In the field of science the most celebrated writers are Soares, on medicine; Giraldes, on geography; Freitas, Da Silva, and Castro, on politics; and Gonçalves and Ferreira, on philology. But the printing-presses of to-day teem chiefly, it must be owned, with translations of the worst French novels, with reprints of ancient mystics, or with religious and anti-religious pamphlets; and their most creditable productions are the renderings of Shakespeare's plays, on which Dom Luis, the reigning king, is at present occupied. See Sismondi, *Literature of the South of Europe* (Eng. trans. by Roscoe, 2 vols. Lond. 1846); Lopes de Mendoga, *Memórias de Literatura Contemporânea* (Lisb. 1855); F. Wolf, *Proben Portugiesischer und Catalonischer Volksromane* (Wien. 1856), and *Studien zur Geschichte der Portugiesischen Nationalliteratur* (Berl. 1859); Francisco da Silva, *Dicionário Bibliográfico Portuguez* (7 vols. Lisb. 1858-62); F. Diez, *Ueber die erste Portugiesische Kunst und Hofpoesie* (Bonn, 1863); and the *História dos Estabelecimentos*

Scientíficos, Litterarios e Artísticos de Portugal (vol. v. Lisb. 1876).

Brazilian literature, an offshoot of the Portuguese, though commencing as far back as the 16th c. with the poet Pinto, remained in complete vassalage to the mother country down to the close of the succeeding century, when the historical writings of Rocha Pitta, and the poems of Santa-Maria and the brothers Mattos, discovered the first germs of native colouring and independent thought. The epic *Uruguay* of De Gama (1740-95) and *Caramuru* of Durão (1737-84), describing the races of America, denote the progress of the movement to nationality, which gained an immense impulse from the removal of João VI. to Rio de Janeiro (1808), and the elevation of Brazil into a separate kingdom. Since 1822 a school of writers has arisen, full of the youth and ardour of a New World, and striving successfully to free themselves from the trammels of the Old. Conspicuous among them are Macedo (born 1820), novelist and playwright; Diaz (1823-64), of whose melodious *Cantos* a complete edition appeared at Leipzig (2 vols. 1865); Araujo Porto-Alegre (born 1806), author of the epic *Colombo* and lyrical *Brasilianas*; and Magalhães, whose epic *Confederação dos Tamoyas* (Rio de Janeiro, 1857), presents a singular blending of Romanticism and national feeling. The best Brazilian historians are Da Silva and Varnhagen. See Wolf, *Le Brésil Littéraire* (Berl. 1863); and Da Silva, *La Littérature Portugaise* (Rio de Janeiro, 1866).

Portulacaceæ, or **Portulacææ**, is a natural order of herbs, or rarely small shrubs, in close affinity to the extensive order *Caryophyllaceæ*. It consists, according to the *Genera Plantarum*, of 125 species, chiefly American, but some cosmopolitan. In Britain it is represented by the little *Montia fontana*, or water-blanks, common in ditches and grassy swamps. Besides Purslane (q. v.), they possess no particular properties or uses. Some, however, are sufficiently ornamental or botanically curious to warrant cultivation, e.g., Chilean or Californian species of *Calandrinia*, *Claytonia Virginica*, from the United States, &c. Two species of *Clatonia* are gradually becoming established as weeds in England, and already find a place in British Floras.

Port Wine is the produce of the Douro district of Portugal, and it takes its name from Oporto, the place of shipment. Pure P. W. is rich and full flavoured, slightly astringent, with a pinky colour; it requires some years to mature, and with age becomes tawny—alcoholic strength, 16 to 20 per cent. Till of late years, however, most of the P. W. shipped to England was largely adulterated with a purple compound called 'jeropiga,' containing elderberries, syrup, and brandy. Adventitious spirit, in the proportion of from 3 to 17 gallons to the pipe of 115 gallons, is added to all export P. W., to hasten its marketable condition by checking fermentation, and to promote keeping qualities. The vintage takes place at the close of September, and extends over a fortnight. The P. W. trade was established in 1678. For some years thereafter the shipment did not exceed 600 pipes; in 1747 it reached 17,000 pipes, and during the period subsequent to 1757, when the trade first became a monopoly, the average annual shipment was 33,000 pipes. The second monopolising company was abolished in 1867, and since then the exports have gradually increased, culminating in 60,549 pipes in 1875.

Posaune, a reed organ-stop. The pipes in connection with the manuals are generally metal, 8 feet in length; those in connection with the pedals, metal or wood, 16 or 32 feet in length. The tone is peculiarly rich and resonant.

Poseidon (connected with Gr. *potos*, *potos*, *potamos*) is in Greek mythology the supreme god of the sea. He was a son of Kronos and Rheia, and a brother of Zeus, Hades, Hera, Hestia, and Demeter. From his palace in the depths of the sea, near Ægæ in Eubœa, he rode in his chariot over the waves, drawn by horses with brazen hoofs and golden manes, and bearing a trident or three-pointed spear, with which he would rend rocks, produce earthquakes, and raise or lull storms. A Life of P. in German by Deetz appeared at Leipzig in 1876. In Homer P. appears as the equal of Zeus in dignity, though his inferior in power. He usually submits to Zeus, but resents his threats, and refuses to be coerced. He stands in the same relation to Nereus as Phœbus to Helios. P. was said with the aid of Apollo to have built the walls of Troy for Laomedon, on whose refusing

the promised reward, he sent a sea-monster, which was about to devour Laomedon's daughter, when it was slain by Hercules. In the war of Troy P. aided with the Greeks, but the *Odyssey* describes him as the enemy of Odysseus, who had blinded Polyphemus, his son by the nymph Thoosa. P. was held to have created the horse in a contest with Athena as to which should bestow on mankind the more useful gift. He was believed to have taught the use of the bridle, and to have originated horse-races. P. appears in numerous legends. In the struggle with the giants he aided Zeus, and pursuing Polybotes, hurled on him the Isle of Cos. He crushed the centaurs under a mountain in the island of the Sirens. At first a rival of Zeus for the hand of Thetis, he retired when Themis told him that Thetis' son would be greater than his father. His worship extended over Ionia, Greece, and Southern Italy; in his honour horse and chariot races were held on the Corinthian Isthmus, and near Mycale the Pan-Ionic festival. P. is often represented in groups with his wife Amphitrite (the mother of Triton), tritons, nereids, dolphins, &c.

Po'sen, a province of Prussia, bounded N. by Preussen, W. by Brandenburg, S. by Silesia, and E. by Russian Poland. Area, 11,126 sq. miles; pop. (1875) 1,606,084. The S. is a continuation of the Upper Silesian mountain-land, rising to 722 feet, and from this the land slopes N. to the valley of the Netze, which, as well as the Prosna and Obra, is an affluent of the Warthe. The greater part of P. is well cultivated, and lies in the level basin of the navigable Warthe, but lakes abound, there is much marsh land, and 455 sq. miles are barren plain. Cattle-breeding and agriculture are the main occupations of the people, and the principal products are wheat, rye, oats, barley, hops, wood, wool, hides, tallow, honey, and wax. The industries include weaving, brewing, distilling, and the manufacture of furs and leather. A salt mine was opened at Wapno in 1872, and operations have recently been commenced on another at Inowracław. Education in P. is lower than in any other province of Prussia. In 1871, of 303,685 children bound to attend school, only 250,372 actually did so. In 1874 there were in P. 2294 common schools, three Catholic, and as many Protestant seminaries for teachers, four first-class 'Real' schools, thirteen higher girls' schools, three 'progymnasien,' and thirteen 'gymnasien.' In 1871 there were in P. 1,009,491 Catholics, 511,292 Protestants, and 61,892 Jews. P. is a part of the Catholic archbishopric of P. and Gnesen, the see of which has remained vacant from the deposition of Ledochowski (April 15, 1874). P., originally a part of Great Poland, was at the partitions of Poland in 1772 and 1773 taken possession of by Prussia, belonged 1807-18 to the Grand-Duchy of Warsaw, and in 1815 was restored to Prussia at the Vienna Congress. From that date, and particularly from 1830, the Prussian Government has constantly striven to Germanise P. by encouraging German immigration, and making German the language of the schools. In February 1846 a rising was planned under Microsslawski, but the attempt miscarried, and many persons were imprisoned. These prisoners were set free by the Revolution in Berlin (1848), after which the request of the Poles that they should have a distinct national position was nominally granted. On the 26th April P. was divided into a Polish and a German part, and the latter was incorporated with the German 'Bund.' This partition being set aside (February 1850), the whole of P. was in 1866 included in the North German 'Bund,' and in 1871 became a part of the new German Empire. See A. Bock, *Statistisches Handbuch der Provinz P.* (Posen, 1865), and H. Wuttke, *Städtebuch des Landes P.* (Leips. 1864-66).

Posen (Polish, *Posnań*), capital of the Prussian province of the same name, is a fortress of the first rank, situated at the confluence of the Cybina with the Warthe, 102 miles N. of Breslau by rail. Among its fifteen Catholic churches are the Cathedral (1775), in the 'Golden Chapel' of which are bronze statues by Rauch of Mieczyslaw I. and Boleslaw I., and the Maria Magdalena or Stanislaus' Church, 175 feet long by 98 broad. P. has also three Evangelical churches, a Greek chapel, and several synagogues, two gymnasia, a first-class 'Real' school, and seminaries for priests and teachers. The town-house (1512-30) is a fine building of Renaissance style. Noteworthy also are the theatre and Raczynski Palace, with a public library of 20,000 vols., and the Government offices and archiepiscopal palace. The fortifications were commenced in

1828, and the chief forts are named *Willa*, *Rochus*, and *Winiary* (the citadel). P. has a large trade in corn, and manufactures linens, woollens, machinery, leather, furniture, oil, tobacco, brandy, and beer. It was made a bishop's see by Otto I. in 968, and in 1253 became a city of the Empire. Here Napoleon I. concluded peace with Saxony (11th December 1806).

Poses Plastiques, another name for *Tableaux Vivants* (q. v.).

Posili'po, the hill which bounds Naples on the W., derives its name from Pausilypon ('*sans-souci*'), the villa of the epicure Vedius Pollio, afterwards the property of Augustus. It is chiefly remarkable for two ancient tunnels of unusual size. The first, which is called the Grotta di P., is upon the Strada di Piedigrotta, is 757 yards in length, 21 to 32 feet in breadth, and of a height varying from 20 to 87 feet. It is mentioned by Seneca and Petronius, and probably dates from the time of Augustus. Medieval superstition attributed its origin to magic arts practised by the poet Virgil, whose villa stood at the foot of the hill. The second, situated on the Strada Nuova di P., is known as the Grotto of Sejanus. It is hewn through the rock, and is 990 yards in length. The construction of this tunnel is ascribed by Strabo to M. Cocceius Nerva (B.C. 37). While being recently cleared of rubbish an inscription was found to the effect that the tunnel had been repaired by the Emperor Honorius about 400 A.D.

Positive Philos'ophy. See COMTE.

Positive Printing (in Photography) is the process pursued in multiplying prints on paper from a negative on glass. Albuminised paper—the kind generally employed—may be readily procured from any respectable dealer; it is rendered smooth and structureless on one side by a coating of albumen impregnated with chloride of sodium or ammonium. The paper is sensitised in the 'dark room' by floating on a solution of nitrate of silver (60 grains to 1 ounce of water), by means of which a chloride of silver surface, which blackens on exposure to light, is obtained. When dry, the sensitive paper is placed in close contact with the collodion side of a negative in a *printing* or *pressure frame* and exposed to sunlight. The printing-frame is simply a shallow oblong box with a plate-glass front and a movable wooden back, hinged across the centre, and provided with transverse bars with screws by which it may be fastened down closely. An image of proper darkness being obtained, allowing for a reduction in the depth of colour in subsequent operations, the print is taken from the frame and washed to remove free nitrates, and it is then toned to a rich hue in a gold salt bath (terchloride of gold, 1 gram; bicarbonate of sodium, 4 grains; water, 6 oz.). In this bath the metallic silver of the print is replaced by finely-powdered gold of a rich purple tint. The print is next washed in water, and is afterwards transferred to the fixing bath (hyposulphate of sodium, 4 oz.; water, 1 pint), in which the unaltered silver is dissolved, and after frequent washing in water the print is dried and mounted. Silver printing, as the process just described is called, has of late years been superseded to a considerable extent by carbon or pigment printing, by which greater permanence is ensured (see PHOTOGRAPHY), but for ordinary photographic prints it is still largely practised. More recently some progress has been made in platinum printing, and what has been accomplished in this direction augurs well for the employment in the future of the most stable metals in P. P. Prints in platinum are obtained by washing the photographic paper with chloride of platinum and ferric oxalate; and under the action of light the latter substance is reduced to the ferrous state, with the formation of a feeble image. The paper is then floated on a neutral oxalate of potash, which instantly precipitates metallic platinum on the ferrous oxalate image, with the effect of intensifying it to a rich warm black velvety colour. The print is fixed by removing free ferric oxalate with a weak solution of oxalic acid, which at the same times purifies the whites, and washing in water concludes the process.

Poss'e Comita'tus, the whole power or people of the county, which the sheriff may summon to his aid for the maintenance of the public peace, and for the pursuit and seizure of felons.

Posses'sion (in Law). Mere P., without a written title, conveys no right to real property. But the ownership of a personal thing creates a presumption of right, which any other

claimant will require to overturn, by proving that the article was once his, and showing how he came to lose P. Hence, when an article whose ownership is in dispute has been taken from the holder by force or fraud, the judge will order it to be restored before entering on the question of right. Any one trying to get P. by force may be opposed by force; but when P. is lost by force or fraud, the original holder must reclaim judicially. See IMMEMORIAL USAGE, PRESCRIPTION, LIMITATIONS, STATUTE OF.

Post Cap'tain (in the British navy), a title now disused, but formerly applied to a captain properly so called, as distinguished from a commander, frequently called captain by courtesy.

Post'ern (Old Fr. *posterne*, now written *pôterne*; Low Lat. *posterna*, *posterula*, from *post*, 'behind'), a small door affording private entrance or egress at the back of an enclosed building. In fortification, the P. is the vaulted passage, closed by a gate, from the ditch to the interior of a fortified place.

Post'-Horn, a wind instrument formed by a simple metal tube.

Post'ing, travelling along the public road with hired horses, either with or without carriages. As a means of conveyance, P. has been almost entirely superseded by stage-coaches and railways. On the Continent of Europe P. is generally a Government monopoly. See POST OFFICE.

Postique (Fr. *postiche*, 'superadded,' Ital. *posticio*, *appositicio*, from Lat. *appositum*, 'placed beside'), in sculpture, an ornament superadded after the completion of the original design.

Post Nup'tial Contract is a pecuniary settlement between husband and wife after marriage. It is effectual if the husband be solvent at the time; but it is ineffectual against creditors at the date when the contract is made.

Post Ob'it Bond is a bond over a reversionary interest in consideration of an immediate advance of money. The bond is valid unless fraudulent. See HAND.

Post Office, a place for the transaction of postal business, such as the receiving and distribution of letters, newspapers, and book-packets; and sometimes also for the transmission of telegrams, granting of money-orders, and banking of savings with Government. In a larger sense, the P. O. is one of the most important departments of the Civil Service, and the transaction of its business is the most extensive and successful undertaking which has ever been carried on by the State. In its present position, it is emphatically a 19th c. institution, a product of the age of steam, electricity, and scientific invention, and in the last hundred years the postal system has made greater strides than in all its history since the days of Cæsar. The name *post* (Lat. *positum*, 'placed') arises from the posts placed along the public roads in ancient states, at which mounted couriers were in readiness to convey imperial edicts from hand to hand. Such posts were known in the Persian and Assyrian monarchies. Communication between ancient Rome and its conquered provinces was kept up by posts, fixed at short distances along the leading highways; a larger post, with full equipments and guards, marking the termination of each day's journey. A similar system is described by Marco Polo as having existed on a gigantic and elaborate scale in China in the 14th c., and that more primitive nations have found posts a necessity is proved by the fact that the Spanish invaders of Peru in 1527 discovered a regular organisation of the kind along the great road from Quito to Cuzco. With the fall of the Roman Empire, posts in Europe fell into disuse. Karl the Great made a temporary establishment of stations for couriers about 807, which was not revived in France until, in 1464, Louis XI. organised a system of mounted posts, 4 leagues apart, for the conveyance of letters of state and public despatches. Private letters in those days were sent by special messengers, and no national arrangements for their transmission were made in France till 1524. The University of Paris formed in the 13th c., and continued for 400 years, a special corps of messengers for its teachers and students, and many of the large educational and commercial institutions of Europe followed its example. A regular system of posts was established between the Hanse towns in the 13th c. In 1516 Franz von Thurn und Taxis instituted communication between the extremities of Karl V.'s dominions, and the successors of his house, extending his system all over Germany, acquired a monopoly of

the posts in that country which they retained till 1806. In England the state-messengers were anciently called *muncil*, and some posts for their accommodation were in existence as early as the reign of King John. Edward IV. organised a system of relays between England and Scotland, to convey the news of his wars, but this was only a temporary expedient. Under Henry VIII., Brian Tuke was appointed to the newly created office of Master of the Postes, his duties being the adequate furnishing of post-horses. A complete organisation of the postal system was not made until the reign of James I., who extended the sphere of the postmaster's home labours, and also appointed a postmaster for foreign parts. A post between London and Edinburgh, to make the double journey in six days, was started in 1635, the postmasters on the route being bound to supply horses at 24d. a mile. In 1649 Edward Prideaux, the Attorney-General for the Commonwealth, established a P. O., with arrangements for the weekly conveyance of letters to all parts of the kingdom. The rates for a single sheet were fixed about that time at 2d. for 80 miles, 4d. for from 80 to 140 miles, 6d. for above 140 miles, and 8d. for letters for the Borders and Scotland. In 1656 they were altered to rates ranging from 2d. for 7 miles to 14d. for more than 300 miles, and although 150 Acts relative to postal affairs were passed in the interim, these charges were not materially changed till 1838. Government officials and members of Parliament had their letters franked, a privilege which was much abused. A post set up in London in 1685 for delivery of letters in the metropolis at 1d. each, first as a private speculation, was subsequently taken on hand by Government, and continued separate from the General P. O. till 1854. A P. O. for Scotland was established in 1695, and a penny post for Edinburgh in 1766. In 1710 the postal service of the British Empire was consolidated, and branches of the General P. O. in London were formed at Edinburgh, Dublin, and New York. Until 1784 the conveyance of letters through the post was often sluggish and unsafe. Post-boys lazily plodded along at the rate of 3 miles an hour, and the robbery of the mails was alarmingly frequent. Consequently the public frequently availed themselves of the services of private carriers and coaches, particularly when letters were pressing, or when they contained valuables. This system was remedied on the recommendation of John Palmer, who, when a theatrical manager at Bath, urged the employment by the P. O. of well-protected mail coaches. His plan was adopted by Government; the first mail coach ran between London and Bristol on August 24, 1784, and Palmer was appointed comptroller of the P. O., in which he proved himself a valuable and efficient organiser. To his efforts the increase of revenue of the P. O. from £150,000 in 1784 to £1,600,000 in 1815 (at about which figure it remained for twenty years) was mainly due. But by far the greatest postal reform is due to Rowland Hill (q. v.), whose scheme of a uniformity of tariff for all distances in the United Kingdom was undertaken by Government under his care in 1840, the inland postage rate for a single half ounce being fixed, after an experimental charge of 4d., at 1d. as advocated by him. His reforms also included the abolition of franking, with the exception of petitions to Parliament, and prepayment by stamps, a double payment being levied on the delivery of unpaid letters. Penny postage gave an immense impetus to trade, and enormously increased the conveniences of private correspondence. The anticipated temporary falling off of the revenue soon disappeared, and the P. O. became a substantial source of income to the nation, while there can be no doubt that the scheme of Rowland Hill has also indirectly increased the revenue to a great extent. In the last forty years the development of the postal system has been marvellous, and this country has taken the lead in all important postal improvements. In 1838 the Money-Order Office became an official department of the P. O. For about forty years previously a money-order business had been carried on by P. O. officials as a private speculation, but in addition to the high commissions levied (8d. per pound), a stamp duty of 1s. was imposed if the order was above £2, and letters containing money-orders were charged double postage. These burdens were removed on the transference of the business to Government, and the commissions on orders were substantially reduced. The introduction of the railway system prodigiously accelerated the speed and aided the regularity of postal transmissions in this country, while the contracts entered into between Mr. Cunard and other great ship-owners for the conveyance of foreign mails produced most beneficial results, so that now there is communication with every

portion of the habitable globe by swift mail steamers. Postage stamps were introduced in 1840, the system being adopted in 1848 by France, and in course of time by all European countries. In 1848 the system of sorting letters in railways and steamers as an economy of time was begun, and in the same year the transmission of books by post was undertaken. Henry Archer's invention for perforating sheets of stamps was purchased in 1852 for £4000. Pillar letter boxes were introduced in 1855. In this year also London was divided into ten postal districts, eight of which are now in existence, viz., Eastern Central (E.C.), Western Central (W.C.), Western (W.), Eastern (E.), North (N.), North-Western (N.W.), South-Western (S.W.), and South-Eastern (S.E.). By arrangement with the National Debt Commissioners, P. O. savings banks were opened in 1861, and the transaction of Government life insurances and annuities for small amounts was begun in 1865. The P. O. acquired power to purchase all the telegraph wires in the country in 1868, and commenced telegraphic business in 1870. Halfpenny post-cards came into use in 1870, and sample post was virtually abolished in 1871 upon the reduction of charges for heavy letters and newspapers.

The *British Postal Guide* published quarterly (price 6d.) by command of the Postmaster-General, contains the chief regulations of the P. O., and is full of valuable information as to rates of postage, &c., the despatch of mails, and other matters. Local postal guides are also published in the principal towns of the kingdom. Some of the more important points in the *British Postal Guide* for April 1878 may be here very briefly summarised.

Inland Letters.—(1) The present rate of postage for a letter not above 1 ounce in weight is 1d.; above 1 ounce but not above 2 ounce, 1½d.; above 2 ounce but not above 4 ounce, 2d., and 3d. additional for each 2 ounce further, till the weight amounts to 12 ounce, when each ounce which the letter weighs is charged 1d. (2) If a letter is unpaid or underpaid, double the amount of the deficiency is charged upon delivery. (3) No letter may be above 18 inches long, 9 inches wide, or 6 inches deep.

Post Cards impressed with a halfpenny stamp may be transmitted between places in the United Kingdom with letters printed or written upon the back. The stout cards are sold at 4d. the half-dozen, the thin at 3½d.

Inland Newspapers and Book-Post.—Inland newspapers may be sent through the P. O. for 4d. for each newspaper, but a packet containing two or more registered newspapers is not charged at a higher rate of postage than a book-packet of the same weight. No packet may be above 14 lbs. in weight, 2 feet long, 1 foot wide, or 1 foot deep. The rates for book-post are 4d. for every 2 ounce, but no book-packet may be above 5 lbs. in weight, 18 inches long, 9 inches wide, or 6 inches deep. Book-packets may contain any number of separate books or other publications, and any quantity of paper printed, written, or engraved upon, but not any communication of the nature of a letter. Circulars, however, i.e., that is letters which, according to internal evidence, are being sent in identical terms to several persons, may be sent by book-post. Newspapers and book-packets may be posted either without a cover or with a cover open at both ends.

Colonial and Foreign Letters, Newspapers, &c.—A table of rates for these, and a calendar showing the mails, are given in the *British Postal Guide*. A postal conference of several nations was held on the invitation of Germany at Bern in 1874, in order that some uniformity in foreign rates should be secured, and a treaty was carried into operation on 1st July 1875. The postal union now includes (a) Europe, the United States, Egypt, and some other places, the rates to those countries being 2½d. per ½ ounce for letters, 1d. per 2 ounce for book-packets, and 1d. per 4 ounce for newspapers; and (b) British India and most European colonies, for which the rates are 6d. per ½ ounce for letters, 2d. per 2 ounce for book-packets, and 1d. per ounce for newspapers, but an extra charge is made for transmission *via* Brindisi. Prepayment is compulsory in some cases of foreign postage, and optional in others. When it is optional, however, an extra charge is made for unpaid letters upon delivery. There is a pattern and sample post to some colonies and foreign countries, and a special Indian parcel-post (the rate of the latter being 1s. per ounce). The rates for colonial and foreign post cards are in all cases half the rates of single letters.

Registration.—The fee for registration of a letter, newspaper, or book-packet passing between any two places in the United Kingdom is 2d. The same fee is payable for a registered letter to

most colonies and foreign countries. The Postmaster-General is not by law responsible for the safe delivery of registered letters or packets, but he is prepared to make good the contents of a registered letter lost while passing through the British P. O. to the extent of £2 in certain cases, provided the conditions as stated in the *British Postal Guide* have been observed. This regulation came into force on 1st January 1878, and was made in order that the public might avail themselves of registered letters for the remittance of small amounts, in preference to money-orders, there having been in the year ending 31st March 1877 a loss of £10,000 on the money-order business of the P. O.

Telegrams.—The rates for inland telegrams are 1s. for the first 20 words and 3d. for every additional 5 words, the names and addresses of the sender and receiver not being counted. Telegrams may be repeated at half cost. The charge for press telegrams is 1s. for each 100 words during the night (6 P.M. to 9 A.M.), and for each 75 words during the day, with an additional 2d. per 100 or 75 words for the same telegram to every additional address. The regulations as to foreign telegrams are founded upon the St. Petersburg Convention of 1875, and will be found with the rates for each country in the *British Postal Guide*. Business firms and private persons may rent private wires from their residences to a telegraphic office at from £5 to £8 per mile per annum.

Money-Orders on post offices in the United Kingdom are granted at the rate of 2d. for sums under 10s., 3d. for sums of 10s. and under £2, and 1d. extra for each additional pound. Money-orders may also be issued payable in France, Germany, Italy, Belgium, Holland, Denmark, Norway, Switzerland, the British Colonies, &c., at rates varying from 9d. to 4s., according to the place and amount of the order.

P. O. Savings Banks are established at many post offices. Deposits of 1s. or any number of shillings are received, but no one may deposit more than £30 in one year, or make a further deposit when the total amount reaches £150. Interest is granted at the rate of 2½ per cent. per annum (4d. for each complete pound in each month), until a deposit accumulates to £200, when interest ceases to be allowed.

Government Insurances and Annuities.—Under Act 27 and 28 Vict. cap. 43 the Postmaster-General may insure lives between the ages of 16 and 60 for not less than £20 or more than £100, and may also grant immediate or deferred annuities of not more than £50.

Miscellaneous business for the Inland Revenue Department is transacted by the P. O., such as the sale of receipt stamps and the granting of dog, gun, game, and other licences.

The P. O. is presided over by the Postmaster-General, who must be a member of either House of Parliament. The office changes with the Government, being given to a supporter of the Ministry in power, who has sometimes a seat in the Cabinet. The General P. O. in St. Martin's le Grand was built in 1825-29, and the buildings for the telegraph department 1869-73. The principal departments of the P. O. are the secretary's office, the solicitor's department, the telegraphing engineering department, the receiver and accountant-general's office, the money-order office, the savings banks department, the circulation department (divided into the controller's office, the inland branch, foreign branch, newspaper branch, the travelling P. O. branch, and registered letter branch), and the returned letter office. The staff of officers attached to the head offices at St. Martin's le Grand amounts to 5500 persons. 400 mail bags leave London daily, having an average weight of 280 cwt. (219 cwt. being newspapers). The night mails leave the General P. O. at 8 P.M., and arrive at all important towns in England and Wales, and also at Edinburgh, Glasgow, and Dublin, in time for delivery next morning before nine o'clock. In the night mails the sorting process is carried on, machinery for exchange of letter-bags at the stations along the route, while the train proceeds at its usual speed, being attached to these travelling post offices. The number of pouches delivered daily in this manner in 1877 was 521, while 478 were received. There is a mail trains service to France, which admits of the delivery in Paris of the English correspondence by the first distribution, and the despatch of letters thence to the provinces by the morning mails. The arrangements for deliveries in London are the most complete in the world. Twelve deliveries are made daily in the Eastern Central District, and eleven within the town limits of each of the other districts. According to the 23d Report of the Postmaster-General for the year ending 31st

March 1877, it was stated that there were at that date 13,447 post offices in the United Kingdom, of which 896 were head offices, and 10,724 road letter boxes, the number of postal receptacles being thus 24,171, as compared with 4500 before the introduction of penny postage. There were 3734 post offices for telegraphic business, in addition to 1636 telegraph offices at railway stations, 5498 offices for money-orders, and 5448 offices to which savings banks were attached. The employees of the P. O. numbered 45,024, of whom 11,654 were in the telegraph department. Returned letter offices were attached to the post offices at London, Manchester, Liverpool, Birmingham, Leeds, Edinburgh, Glasgow, and Dublin. The General P. O. for Scotland is at Edinburgh, and for Ireland at Dublin.

The following table shows the estimated number of letters, post-cards, book-packets, and newspapers which passed through the post in 1876, as also the rate of increase on the previous year, together with the proportion of letters to population:—

	Number of Letters in 1876.	Increase p. cent. on No. in 1875.	Number of Post Cards.	Increase per cent. on 1875.	Number of Book Packets and Newspapers.	Increase per cent. on 1875.	No. of Letters per head.
England and Wales, . . .	856,042,400	1.1	78,412,100	6.9	241,866,100	6.7	35
Scotland, . . .	91,120,700	0.2	9,640,100	4.7	32,778,100	1.09	26
Ireland, . . .	71,792,100	1.7	4,883,500	7.5	24,146,600	3.0	13
United Kingdom, . . .	1,018,955,200	1.0	92,935,700	6.7	298,790,800	6.8	31

The total estimated number of newspapers was 125,065,800. The number of letters registered in the United Kingdom during 1876 was 5,095,116, or about 1 registered to 200 ordinary letters. The estimated number of letters delivered in each country during the last ten years is in millions as follows:—

	England and Wales.	Scotland.	Ireland.
1867	640	76	59
1868	673	78	60
1869	683	79	62

1871	721	80	66
1872	737	82	66
1873	756	84	67
1874	804	90	73
1875	847	91	71
1876	851	91	72

In the year ending 31st March 1877, 17,822,921 inland money-orders were issued for £27,516,698, the average value being £1, 10s. 10d.; 145,838 money-orders were exchanged between this country and the colonies, and 211,163 between this and foreign countries. The sums deposited in P. O. savings banks (in 3,116,136 deposits) amounted to £8,982,350, and the total amount of deposits at the end of the year was £28,111,565; 3970 insurance contracts for £315,211 and 6682 contracts for annuities of £82,390 were in force on 31st December 1876. In the fifteen months ended 31st March 1877, the number of telegraphic messages sent was 26,440,439 (England and Wales 13,485,279, London 8,188,107, Scotland 2,905,242, and Ireland 1,861,811), being an increase of 960,000 on the preceding fifteen months. The length of the postal wires in March 1877 was 107,600 miles, 5800 of which were rented by private persons. Among the most curious statistics of the Postmaster-General's Report (1877) are the announcements that 14,346 letters reached the Returned Letter Office during the year destitute of covers; that 78,575 postage stamps were found loose in the different post offices, and 33,100 letters were posted without addresses. In a period of fifteen months the number of letters received in the Returned Letter Office was 5,897,724, and it was found possible to return to the writers or to re-issue nearly nine-tenths of the whole number received. The revenue from the P. O. for the year ended 31st March 1878 was £6,150,000 (an increase of £150,000 from the previous year), and £1,310,000 from the Telegraph Department. The expenditure was £3,185,346 for the P. O., £1,137,000 for the telegraph

service, and £763,000 for the packet service. The net revenue from the P. O. has been quadrupled since 1840. In the packet service the most important home contract is for the mail service between Holyhead and Kingstown, which costs the country at present £85,900 per annum. The most important foreign contract is for packets to the E. Indies, China, and Japan (£430,000). For conveyance of mails to the United States there are three excellent services in each week to New York.

Most foreign countries have modelled their postal system on that of Great Britain. The following table affords a comparison of the number of letters, newspapers, and book-packets passed through the post in the year 1874 in the great powers of Europe and the United States:—

	Number of Letters.	Number of Newspapers and Book Packets.	Number of Letters per head of the Population.
Great Britain, . . .	967,000,000	259,000,000	30
Germany, . . .	697,000,000	350,000,000	17
Austro-Hungary, . .	313,000,000	104,000,000	8
France, . . .	334,000,000	331,000,000	9
Russia, . . .	63,000,000	24,000,000	1
Italy, . . .	104,000,000	94,000,000	4
United States, . . .	973,000,000	...	23

In all these cases the receipts considerably exceeded the expenditure except in the United States, where the expenditure was \$33,611,000, and the receipts \$27,441,000. The deficit in the United States was due to the low postage on newspapers and book-packets, and to the vast extent of the mail services in America through thinly populated districts.

References.—Besides the works already alluded to, see *Her Majesty's Mails*, by W. Lewins (Lond. 1864); *History of Banks for Savings*, by W. Lewins (Lond. 1866); *Geschichte der Preussischen Post*, by H. Stephan (Berl. 1859); *Notice sur l'Origine du Prix Uniforme de la Taxe des Lettres* (Par. 1872), and *Histoire de la Poste aux Lettres*, by Arthur de Rothschild (Par. 1873). The United States *Official Postal Guide* is published by Houghton & Co. of Boston, by authority.

Laws Regarding the P. O.—Letters may be detained and opened by warrant from the Home Secretary of State, but severe penalties are imposed on any one wilfully detaining or opening a letter addressed to another without this authority. The Postmaster-General is not a common carrier for hire, therefore he is not liable for constructive negligence, and no action can be maintained against him for the loss of bank-notes, bills, or other articles sent by post. Anything not dangerous may be sent by post. Petitions and addresses to the Queen are exempt from postage, so are petitions to Parliament, if sent to a member of either House in an open cover.

Any one illegally conveying a letter incurs a penalty of £5 for every offence, and £100 for every week during which the practice is continued. The sender also incurs a penalty of £5.

Postulate (Lat. *postulo*, 'I demand') is a proposition which must be granted as a preliminary to establishing a system or pursuing an argument. Thus elementary geometry, as developed in the books of Euclid, makes nominally three postulates. In reality, however, it is based on four, since the so-called axiom concerning parallel lines is by no means self-evident, and is strictly a P.

In *Philosophy*, a P. is neither a hypothesis nor a corollary, but is connected intimately with some other proposition which cannot be denied, and which involves the acceptance of the P. Kant's postulates are three:—1st, I am under obligation, and therefore I am free; 2d, Practical reason tends necessarily to the sovereign good, and this supposes continuity of existence; 3d, The sovereign good supposes happiness, and this results from conformity of all things with a will. These three postulates are freedom, immortality, and God. The logical postulates are the laws of thought.

Postures. In the primitive Church four P. were generally practised and allowed in the adoration of God. (1) The usual posture of devotion at their ordinary morning and evening services on week-days and on fast-days was kneeling; but (2) on the Lord's day and the fifty days between Easter and Pentecost standing

was the posture used, as a symbol of Christ's resurrection. (3) Bowing down the head, or an inclination of the body between standing and kneeling, was chiefly used in receiving the bishop's or priest's benediction. (4) Prostration, or lying in the humblest manner on the ground, 'was the proper posture for extraordinary humiliation, when men had some singular request more earnestly to recommend to God,' e.g., when the lapsed were suing for admission to Penance (q. v.).

Potail' (patil), the name used in India, especially in the Bombay Presidency, for the village headman. It is of uncertain derivation, but evidently of Mahratta origin. The Bengal equivalent is *mundul* or *pradhan*. Where the village system still retains vitality, the headman has control of the financial affairs of the villages, is superintendent of the police, and exercises certain magisterial functions. He is also the chief medium of communication with the Government or the landholder, and is always treated with great respect. The office is generally hereditary, and to a certain extent saleable.

Potash. See POTASSIUM.

Potash, Pharmaceutical Preparations and Medicinal Properties of. The salts of potassium are very poisonous to the lower animals, and their action upon man, as upon other mammals, results in great feebleness of pulse and lowering of temperature, the most marked action being upon the heart. When a frog is killed by salt of P., the heart is arrested in diastole, and the action upon the heart has been heretofore supposed to be a local one, the diastolic arrest being due to a direct impression upon the cardiac muscles. Dr. Ringer and Dr. Murrell have recently conducted a series of exhaustive experiments on the action of the P. salts, and they conclude that P. paralyzes the central nervous system, the nerves, and the muscles, and that this paralysis is not due to the action of P. salts arresting the heart's action. Regarding the action of chloride of potassium they give the following summary of the conclusions arrived at:—(1) It paralyzes all nitrogenous tissues; (2) it acts by an equal affinity for all protoplasm, and it destroys the tissues in the order of their vital endowments; (3) it arrests the heart, owing to its common action on all protoplasm, not from a special action on that organ; (4) arrest of the circulation, itself a paralyzing influence, must in some degree assist the direct action of the P. on the tissues; (5) by arresting the circulation, P., probably at an early stage, depresses the reflex function of the cord in the summer months indirectly through arrest of the circulation in the brain. In explanation of the slow paralysis of muscle induced by P., Dr. Ringer says that P. being a powerful poison both of nerve and muscle tissue, when absorption takes place and the P. salt reaches the heart, this organ becomes paralysed, and thus the passage of the salt through the circulation is prevented. It then spreads slowly by diffusion through the tissues, and thus by degrees very tardily poisons them. The effects of other nerve and muscle poisons are doubtless thus modified, and the rate of paralysis will depend not only on their poisonous action, but likewise on their diffusibility, and the distance the nerves and muscles are situated from the point of subcutaneous injection.

The British Pharmacopœia contains the following preparations of P.—*Caustic P.*, sometimes called *hydrate of P.*, prepared in the form of hard white pencils, is very deliquescent, and powerfully alkaline and corrosive. It is chiefly employed as an escharotic for the destruction of tumours and malignant ulcers, and for making caustic issues. *Liquor potassæ*, or *solution of P.*, contains in 1 fluid drachm, $3\frac{1}{2}$ grains of anhydrous P., and is prescribed in doses of from 15 to 60 minims three times a day in milk or *mistura amygdalæ*. *Liquor potassæ* is an antacid, diuretic and antilithic, and is useful in dyspepsia, in skin diseases dependent on a morbid condition of the stomach, as an alternative in inflammation of the serous membrane, as in pleuritis, pericarditis, and peritonitis, and also in syphilis and chronic rheumatism. It is also used externally as a lotion in certain chronic skin diseases, and as a stimulating lotion generally. The antidotes to a poisonous dose of liquor potassæ are dilute acetic acid, citric acid, lemon juice, vegetable acids generally, fixed oils and demulcents. *Potassa sulphurata*, or *sulphurated P.*, is given internally for scabies in doses of from 3 to 8 grains; but it is chiefly employed externally in the form of ointment ($\frac{7}{8}$ to $\frac{3}{4}$) in various skin affections, such as scabies, lepra, and psoriasis; and

for the formation of sulphur baths, the strength of which should be from 2 to 6 ounces of the drug in 30 gallons of water. The baths should be taken warm, the patient remaining in them for twenty minutes to two hours; they are recommended in cases of chronic rheumatism. The *acetate of P.* is given in doses of from 10 to 20 grains as a diuretic, and from 120 to 180 grains as a laxative, and is best administered in simple solution, with a little sugar. *Acetate of P.* has been prescribed with great success in acute rheumatism. *Bicarbonate of P.* is given in doses of from 10 to 20 grains as an antacid or antilithic, 60 grains as a diuretic, and 30 to 40 grains, freely diluted, every four hours in acute inflammatory rheumatism. The best mode of administration is in aerated water, or some bitter infusion. *Carbonate of P.* is given in doses of from 10 to 30 grains as an antacid, antilithic, and diuretic, and is contained in decoctum aloes compositum, liquor arsenicalis, and *mistura ferri composita*. It is frequently employed in the preparation of effervescing draughts, 20 grains being neutralised by 17 grains of citric acid, 18 grains of tartaric acid, or by half a fluid ounce of lemon juice. *Chlorate of P.* is given in doses of from 10 to 20 grains in water three or four times daily, as a stimulant and diuretic in the low stage of typhus fever, smallpox, and scarlatina, and in all forms of disease due to blood-poisoning. Chlorate of P. is of great value in various forms of stomatitis, and especially in the follicular or aphthous stomatitis of children. When used locally it acts as a stimulant to the various mucous membranes, and it has been recommended in the form of enema in dysentery and cholera infantum. It is prepared in the form of lozenges, each containing 5 grains. An agreeable and useful gargle may be prepared with 1 drachm of the carbonate of P., $\frac{1}{2}$ oz. of honey, and 8 oz. of water. The *citrate of P.* may be given in doses of from 20 to 60 grains in water, as a refrigerant, diuretic, and mild alkaline laxative, in cases of gout, rheumatism, uric acid gravel, and also as a drink in scurvy. C. of P. is eliminated in the urine, rendering it neutral or alkaline. An excellent method of administering C. of P. is in the form of an effervescing draught, which may be prepared as follows in two solutions, one consisting of lemon juice and water, equal parts; or of citric acid $\mathfrak{z}\text{ss}$, water $\mathfrak{z}\text{iv}$; the other carbonate of P. $\mathfrak{z}\text{i}$, water $\mathfrak{z}\text{iii}$. An ounce of each of the solutions to be put together, and the whole to be drunk during effervescence. *Nitrate of P.*, or *nitre*, is given in doses of from 5 to 20 grains, as a refrigerant and diuretic; and from 20 to 30 grains as a vascular sedative in acute inflammatory diseases, and especially in acute rheumatism. Combined with tartar emetic and calomel it is given to promote the secretions of the liver and skin, and to lessen febrile excitement. Nitrate of P. is used for inhalation in cases of asthma, by soaking porous paper in a saturated solution, and then drying it, and burning it in a candlestick. *Sulphate of P.* is given in doses of from 10 to 20 grains as an alternative; and 60 grains as a purgative in combination with rhubarb, in jaundice and dyspeptic affections. It forms an ingredient in the compound colocynth pill, and in compound ipecacuanha powder. *Tartrate of P.* is prescribed as a diuretic in doses of from 20 to 60 grains; and, as a purgative, 120 to 200 grains. *Acid tartrate of P.*, known popularly as *cream of tartar*, is much used in febrile and dropsical affections. As a refrigerant or diuretic, it is given in doses of from 20 to 60 grains; as an aperient, 60 to 120 grains; and as a hydragogue cathartic $\frac{1}{2}$ drachm to 1 ounce.

There are several other preparations of P., the medicinal properties of which depend more upon the substances with which it is combined. The *bromide of P.* is given in doses of from 20 to 60 grains in the twenty-four hours, in cases of chronic glandular enlargements, as of the liver, the spleen, and in bronchocele and scrofula. It is also highly efficacious in keeping off attacks of epilepsy. The *iodide of P.*, in doses of from 2 to 10 grains, is more efficacious than the bromide, in cases of glandular enlargements, and it is also used in chronic rheumatic affections, and in cases of secondary syphilis, in drachm doses, in the twenty-four hours, in combination with tincture of bark. Iodide of P. is contained in the liniment and the tincture of iodine. The *permanganate of P.* is prescribed in doses of from 1 to 2 grains in diabetes, and to correct offensive evacuations; but it is more generally used as an antiseptic and deodoriser. Externally it is applied as a caustic and deodoriser to offensive ulcers and cancers. It is also much used as a disinfectant. The *liquor P. permanganate* is given in doses of from 2 to 4 drachms; and, diluted with 40 parts of water, it is used as a gargle or as a

cleansing wash for diseased surfaces. When used as a disinfectant, it should be added to the matter operated upon until the characteristic purple colour is apparent. This preparation is the same as Condy's Fluid, but half the strength. For the action of the P. salts, see the *Journal of Physiology*, March No., 1878, p. 73.

Potash Water. See AERATED WATERS.

Potassium ($K=39.1$), the most typical of all the metals of the alkalis. These metals are, beginning with the lowest atomic weight, lithium, sodium, P., rubidium, cesium. They are soft, white, light, and easily fusible. They oxidise rapidly in the air, their affinity for oxygen increasing with the atomic weight. Consequently they all decompose water, evolving hydrogen and forming a soluble hydrate, an action which is accompanied by a development of heat. Excepting lithium and sodium, their action generates sufficient heat to inflame the hydrogen. In the case of P., the flame gives a purple light because of the presence of the vapour of the metal. The hydrates of all are very soluble in water, can be fused and volatilised at a high temperature, hardly decomposing by heat, absorb carbonic acid from the air, and are useful in the arts for saponifying oils and fats and forming soluble soaps. The chlorides, sulphides, sulphates, phosphates, and carbonates are soluble in water; and the sulphates form with the sulphates of aluminium and the allied metals characteristic double salts known as *alums*. These, excepting lithium-alum, which has not yet been crystallised, crystallise in octahedra. They are all monads, and the type of their salts is MCl , where M stands for the metal. The oxides then have the composition M_2O , and the hydrates or *caustic* alkalis the composition MOH . Besides the oxide, however, which is a strong base in all, P. forms other two, the peroxide K_2O_2 , and the tetroxide K_2O_4 , both of which are unstable and of little practical interest. Caustic potash (KOH) is prepared by mixing a solution of the carbonate with slaked lime—

It is a valuable agent in the laboratory, decomposing the salts of all metals which form oxides insoluble in water, and precipitating this oxide in the form of the hydrate. Potash is found in all fertile soils, and is necessary for the growth of plants, in the tissues of which it exists, combined with the radical of some vegetable acid. When the plant is burned the salt is decomposed, and in the ash that remains the P. exists chiefly in the form of the carbonate. This ash washed and evaporated forms the *potash* of commerce. From the carbonate thus obtained, the metal may be prepared by distillation in the presence of charcoal at an intense heat, when P. vapour is given off, accompanied by carbonic oxide. A bicarbonate ($KHCO_3$) is also known. It is less soluble than the carbonate, and is prepared by passing carbonic acid gas through a strong solution of the latter. Another important salt which occurs native is the nitrate (KNO_3). It is found as an incrustation on the surface of the soil in some parts of India, and is believed to be the result of decomposition due to fermentation. For a discussion of its other sources, and of its use in the manufacture of gunpowder, see NITRE. The chloride (KCl) occurs in certain saline deposits associated with the sodium chloride ($NaCl$). It is useful for preparing other P. salts. Thus, it decomposes the chlorate of calcium, made by saturating hot milk of lime with excess of chlorine, so as to give chloride of calcium and P. chlorate ($KClO_3$). This salt is important as a source of Oxygen (q. v.). P. was discovered in 1807 by Sir Humphrey Davy, who obtained it by electrolysis of caustic potash. Its spectrum, like the spectrum of all the metals of the alkalis, is easily recognised, consisting of three well-marked bright lines, two in the red and one in the extreme violet.

Pota'to is the equivalent of the Spanish 'Batatas,' a name originally applied to the plant now distinguished as Sweet-P. (*B. edulis*, q. v.), but on the subsequent introduction of the widely different *Solanum tuberosum*, transferred to the latter. This important species of *Solanaceæ* (q. v.) is a native of the Andes of S. America, particularly of Chili, but is not absolutely trans-equatorial, as it extends into Columbia; it is also wild in the Argentine territory. The Spaniards are believed to have first brought it to Europe early in the 16th c. It afterwards found its way into Italy, and from that country was carried to Flanders, whence in 1598 it was sent (from Mons) to

L'Ecluse at Vienna, who records that in a short time it spread through Germany. Meanwhile it had been introduced by English adventurers—first, some say, by Sir John Hawkins in 1563, certainly ten years later by Sir Francis Drake (to whom a statue is erected at Offenburg, in Baden, inscribed 'the immortal introducer of the P. into Europe'), and again by colonists, under the auspices of Sir Walter Raleigh, returning from Virginia in 1586. The plant was grown from this period on Raleigh's estate near Cork, and became known as a food in Ireland long before it was cultivated in England. Gerard, in his *Herbal* (1597), gives a figure of it under the name of *Batatis Virginiana*, and it is noteworthy that in the title-page portrait he is represented holding a branch of the P. In his garden *Catalogus* of 1596 and 1597, he has the plant under the name of *Papas orbiculatus*, bastard potatoes. In 1619 it appears amongst the articles provided for the household of James I., and in 1663 its valuable properties having become more generally known, the Royal Society took measures to encourage its cultivation; but a long time elapsed before it was grown to any extent. To Scotland the P. was introduced in 1725, and a few years later a labourer named Prentice gets the credit of field culture in the neighbourhood of Kilsyth, whilst Lord Kaimes and Lord Gray were active advocates of the extended cultivation. In France for a long period prejudices existed against it—its cultivation was believed to injure the land, and its use as food to generate disease. Only after long-continued exertions on the part of Parmentier, and within the present century, did it become popular in that country, where it now forms, as also throughout the temperate British dominions, the most useful article of vegetable food next to the cereals. As an esculent the P. is excellent in whatever way it may be dressed, whether plain boiled, steamed, fried, or roasted. For cattle it is used raw or boiled. In addition to these services the tubers give about 15 per cent. of starch, equal to arrow-root, which, combined with wheat flour, makes a good bread, is the basis of certain farinaceous foods, and by being heated with mineral acids or malt, can be converted into dextrin and dextro-glucose, useful for many purposes. Dextrin, as a substitute for gum, is also obtainable by subjecting the dry starch to a heat of $400^\circ F$. By distillation a strong coarse spirit is obtained from it, which passes under the name of British brandy; it is prepared in large quantity in Germany and other countries of Europe. The skin of the P. contains a poisonous substance called *solanine*, which is dissipated or destroyed during the process of boiling or steaming. Being rather deficient in flesh-forming properties, the P. cannot be used as a complete food, but is best employed as an addition to pulse, lean meat, or other nitrogenous foods' (*Church*). The tender tops of the plant are eaten as spinach in Canada, &c., and the unripe berries are sometimes pickled, or when ripe prepared like those of its ally the tomato. The varieties of P. are very numerous, some early and some late; these again differing considerably not only in foliage or habit, but in size, form, colour, and quality of the tuber. As new sorts are constantly being raised, whilst those long in unchanged culture degenerate, the specialties continue changing from year to year, and as a rule each district has its particular favourite. Only such varieties should be grown that are floury, that ripen early, that will keep late, and that yield a good crop. The propagation is by cuttings of the tuber, technically called 'sets,' which should be taken from partially ripe tubers, or sometimes small undivided ones are used. In Britain the planting should be as early in March as circumstances will permit, and should be made in open ground, fully exposed to the light. It is a great disadvantage to set so thick that when the tops grow the plants smother or shade each other. The crop may be increased by destroying the flowerers as they appear. For the production of young potatoes during winter, and for the early supply, special methods of cultivation are adopted. To keep the stock after it is taken up in autumn, frost-proof cellars or 'pits' are necessary, in which the tubers are laid in layers or ridges of moderate thickness, when they will preserve well without sprouting or losing flavour. Of the various diseases the P. is subject to, the most momentous is that commonly called the P. Disease (q. v.). What is called by growers 'the curl' may in general be prevented by employing healthy sets, and giving proper attention to soil and culture. The 'scab' seems to be caused by certain manures and soils. Other species of *Solanum* have recently been recommended for development by cultivation as P.; of such is *S. Fendleri* of New Mexico, which is capable

of bearing a temperature of zero; four or five species from the elevated districts of Mexico; *S. Maglia* from Chili, and *S. immitis* from Peru.

Many different kinds of insects attack the P., and of these by far the most destructive is the Colorado P.-beetle (*Doryphora decem-lineata*). It is a hemispherical, yellow insect, about a third of an inch long, with ten black stripes on the elytra. First described by Thomas Say, who found it in Missouri in 1824, it was little heard of till 1859, but since then it has rapidly spread, always advancing eastwards. In 1875 it was common from Virginia to Maine, and even abounded in the streets of the larger cities. The insect hibernates, and the period of oviposition covers about a month for each female, the average number of eggs produced by each being about 500. The chief means as yet adopted to check the ravages of the beetle are (1) destruction of the beetles and eggs by hand; (2) isolation of the P. fields; and (3) the use of Paris green, either in the form of a powder (mixed with ashes, bran, or lime), or dissolved in the proportion of a tablespoonful in three gallons of water.

Potato Disease, or Potato Murrain. This scourge—threatening the existence of the potato as a food-crop by the importance there was every probability of it assuming—first made its appearance in England in 1845, having been experienced somewhat earlier in America. The year following it created the Irish famine, and since that period has caused a variable but immense annual destruction of the valuable esculent in all districts of Britain and of Europe. The murrain has been equally bad in the wettest and the hottest seasons, and thus far has baffled all researches of practical and scientific men to discover a remedy. Innumerable plans have been suggested, some of which for a time have seemed to answer, but the extended result has always been disappointment. The matter has been decided to this extent—that the disease is the work of a little mould called *Peronospora infestans*, which penetrates into the substance of the leaf, its conidia-bearing filaments projecting through the stomata; that it works its way down the stem, resulting in the rapid putrescence of both roots and suckers; and infests the tubers, producing in them a characteristic brown mottled appearance, and brown spots on their surface—sure precursors of their more or less deferred decay. It attacks the potato in the last stages of growth in August or September, so that it is rational to recommend the cultivation of early varieties, to plant early, and get the crops safely harvested before the period of visitation. We do not fully know the circumstances that induce the appearance of the fungus at the particular time above specified, but peculiar electric conditions of the atmosphere are strongly suspected of having something to do with its development. The recent researches of Mr. Worthington Smith have shown that the 'resting spores' of the *Peronospora*, and of an allied fungus (*Fusicladium solani*), which almost invariably accompanies it, lie dormant in the remains of the foliage and in the tubers of the potato during a period of ten or eleven months, then burst into activity, and carried far and wide by the wind, repeat their course of destruction on the new crops. The seat of danger is therefore manure heaps and other accumulations of diseased potato litter—clearly pointing to the advisability of its absolute destruction. The starch even in badly diseased potatoes is but little affected by the *Peronospora*, and may be obtained from the pulped mass by washing it on a cloth in a stream of water.

Potato-Fly (*Anthonomyia tuberosa*), a species of flies or *Diptera*, the larvæ of which infest potatoes. The adult fly is about half an inch long, and is coloured of a greyish-black hue.

Potchinky, a town in the Russian government of Nijni Novgorod, 115 miles S.S.E. of the city of that name. It exports corn and potash. Pop. 7554.

Potem'kin, Grigoriĭ Alexandrovitch, the most powerful and famous of the favourites of Catharine II. of Russia, was born near Smolensk, September 1739. Though at first destined for the Church, at an early age he entered the Russian army, and having attracted the notice of the susceptible Empress at a review in 1762, was appointed colonel and gentleman of the bedchamber. In 1774 he succeeded Orlov as her avowed lover, and gave place to a successor in 1776, without, however, losing his influence over the Empress. His intimate knowledge of her character, and his power of adapting himself to circumstances, enabled him to retain his political

power, and made him until his death the most important person in Russia. He constantly promoted territorial increase in the S., and was the main promoter of the Turkish war in 1771-72 which cost the Turkish Empire the Crimea and Kuban, and first gave Russia a footing on the shores of the Black Sea. He was now appointed governor of the Crimea and Grand Admiral of the Black Sea, while the indulgent Empress built him a magnificent palace in St. Petersburg, styled from the new name of the conquered province, Taurida, and conferred upon himself the surname of Taurisschesky. In 1787 she visited his government, and was received by the skilful courtier with the greatest magnificence, villages and towns of painted wood even being erected along her route and filled with people, to give the appearance of prosperity. He did much, however, in reality to improve his province, building the towns of Kherson, Kertch, Nicolaiev, and Sebastopol, and fitting out a fleet to defend the coasts. When the Turkish war broke out in 1787, P. was put at the head of the army, with Suvarof and Repnin as his lieutenants. His career was one of continued victory, and after the capture by storm of Otchakov, in which 25,000 Turks were put to the sword, P. returned to St. Petersburg, March 1790. Here he was received with the most magnificent fêtes, and presented with 100,000 roubles. He soon returned to the camp, but his ambitious wishes were checked by the determination of Catharine to make peace. The preliminaries were signed August 11, 1791, and P. died on the 16th of October following, of an epidemic raging at Jassy. In 1830 the town of Kherson erected a monument to its founder. See *Privatleben des Fürsten von P.* (Graz, 1793); Cérenville, *Vie du Prince P.* (1807-8); Prince de Ligne, *Mémoires de la Cour de Russie* (Par. and Berl. 1859).

Potent (Fr. *potence*, Low Lat. *potentia*, 'a crutch'), in heraldry, is one of the eight furs, and implies that the field is covered with figures of 'potents,' an old word signifying 'crutches.' P. is of the alternate tinctures of argent and azure. In *P.-counter-P.*, or *varry-cuppy*, potents of the same tincture are ranged base to base and point to point.

Potentée, in heraldry, one of the divisional lines, formed by a row of crutch-shaped figures.

Poten'tial is a function of great importance in the theory of attractions. Its value was first recognised by Laplace in his investigations upon the figure of the earth, but it received its present name from Green, who applied it with great power to electrical problems; and now it forms the central conception of the mathematical theory of attraction. Sir W. Thomson has defined the P. of a conductor charged with positive electricity as the work which must be spent in removing unit of negative electricity from the surface to an infinite distance, supposing the distribution to remain constant during the operation. With a slight modification the definition may be made to apply to the cases of magnetism and gravitation. Further, the P. at any point with reference to the attracting body is the work which must be done to remove unit quantity from that point to an infinite distance. Hence the work done upon unit quantity in removing it from one point to another is measured by the difference of the potentials at these points. If the points are very close together, then the work done may be represented by the product of the distance into the average force overcome through that distance; and therefore the force at any point in any direction due to an attracting system is the rate of increase of the P. at that point per unit of length in the given direction. In electrokinetics there cannot be a transfer of electricity without a difference of P. Accordingly, P. is in the theory of electricity what temperature is in the theory of heat, what pressure is in hydrodynamics. As heat flows from a body of higher temperature to a body of lower temperature, as fluid flows from the place of greater pressure to the place of less, so does electricity flow from the region of higher P. to the region of lower. In the mathematical theory of attractions, the existence of a P. for a given system of forces is the criterion that that system is a conservative system—i.e., that it satisfies the principle of the conservation of energy. All known forces belong to this category. See ELECTRICITY, ENERGY, MAGNETISM.

Potentilla is the representative genus of the tribe *Potentilleæ*, of the natural order *Rosaceæ*, having much in common with the strawberry, but differing in this, that the achene

('seeds') are arranged upon a dry, instead of a fleshy receptacle. It includes about 120 species of perennial herbs or rarely shrubs, nearly confined to the temperate, Arctic, and mountainous regions of the northern hemisphere. *P. fruticosa*, a much-branched shrub with golden-yellow flowers, a very local British plant, but extending from W. America across Europe to the Himalaya, is often planted in shrubberies. The rootstock of *P. Comarum*, a strong perennial of bogs and marshes, is powerfully astringent, and yields a yellow dye; and that of *P. Tormentilla* with like properties is used for tanning and in rustic medicine. *P. anserina*, called silverweed from the soft, silky, silvery appearance of its pinnate leaves, is a common roadside plant of a very wide range; and its rootstock in times of scarcity has served for food in the Hebrides. About seven other species are natives of Britain, and various others are frequently seen in gardens. The name *P.* comes from the Latin *potens*, alluding to the powerful medicinal effects formerly ascribed to some of the species, and the common name of 'cinquefoil' is given to the genus from a number of the species possessing leaves of five leaflets.

Poten'za (*Potentia*, an ancient Lucanian town), a city of S. Italy, capital of the province of P. or Basilicata, 54 miles E. of Salerno. It is a bishop's see, and has considerable trade in silk, honey, and cheese. P. was much shaken by earthquakes in 1273, 1694, and 1812, and all but totally destroyed by that of December 17, 1859. Its walls, however, and fine Doric cathedral were not seriously injured. Pop. (1874) 18,513.—**P. Picena**, in Central Italy, province of Macerata, on the Adriatic, 23 miles by rail S.S.E. of Ancona, had once considerable trade, but its harbour is now almost wholly silted up. Pop. (1874) 6763.

Pot'-Herbs include the plants of secondary importance cultivated for culinary purposes, such as parsley, fennel, chervil, coriander, &c.

Pot'i, a fortified seaport of Russia, in Transcaucasia, government of Kutais, on the S. branch of the Rion, near its mouth in the Black Sea, 190 miles W. of Tiflis, with which it is connected by railway. A great harbour is being (1878) constructed here to meet the increasing trade, and 80 fathoms of the N. wall and 120 of the S. have been run out, and have proved effective in heavy gales. It is proposed to curve the S. wall northwards and to extend it until a depth of 30 feet is obtained at the entrance. The construction of an iron bridge across the Rion had in 1876 seriously interfered with the trade of the port, ships having to load and unload at the bar. In 1875 the exports amounted in value to £746,928, and the imports to £698,707, while the port was entered and cleared by 476 vessels of 124,358 tons, of which 47 were English of 31,015 tons. The imports are sugar, tobacco, groceries, salt, iron, and ammunition, the exports wine, hides, leather, tallow, silk, cotton, woollen, boxwood, and bristles. Boxwood of the finest quality will be largely procured in the Abkassian forests when the Government prohibition is removed, as it will probably be shortly. The town is fever-stricken and destitute of sanitary works. Pop. (1876) 4500.

Potichomanie is a process by which pretty and tasteful imitations of opaque painted porcelain can be made from vases, &c., in plain clear glass. It consists in gumming painted or printed designs, cut out of paper, to the inside of the glass article, coating the paper with size, and afterwards applying white or tinted oil paint over the whole internal surface.

Pot-Metal is the name given to a kind of glass which has been coloured by the addition of the colouring matter while the glass was still in a molten condition.

Poto'mac, a river of the United States, rises in the Alleghamies in two branches, which unite 20 miles S.E. of Cumberland, Maryland. After a S.E. course of 400 miles between Maryland and Virginia and W. Virginia, it falls into Chesapeake Bay. P. is navigable as far as Cumberland, and for men-of-war as far as Washington, to which point (125 miles from the mouth) the tide ascends. It is from 6 to 8 miles broad for the last 100 miles. Above Washington are several cataracts; the river falling 1160 feet in the 220 miles between Westport and that city. The scenery here is very picturesque, especially at Harper's Ferry, where its largest tributary, the Shenandoah, joins the P. on the right. Other tributaries are the Savage,

Monacacy, and Acquia Creek. The whole course of the P. formed an important strategical line during the American Civil War.

Potoroo. See KANGAROO RAT.

Poto'si, the third largest town in Bolivia, is situated at an elevation of 13,024 feet above the sea level. The surrounding country is barren and desolate, and the climate is very trying, extremes of heat and cold being experienced within twenty-four hours. According to Captain Musters, the cold is so intense at P. that children born there are generally dead or blind. The mineral wealth of the district is immense, consisting principally of silver. Gold and copper are also plentiful, but are now little worked. The silver mines were accidentally discovered in 1545 by an Indian while hunting, and between that date and 1800 there were coined at P. \$823,950,509. The ore is extracted chiefly from a conical mountain called the Cerro de P., 15,977 feet high, and honey-combed to within 125 feet of its summit by thousands of workings. The upper half being now nearly worked out, and the difficulty of keeping down the water in the lower portion being great, the mines are in a languishing condition, and the average amount coined annually is now only \$2,000,000. The population of P., which was once as high as 170,000, had fallen at the last census in 1861 to 22,580; and much of the town is in ruins. The principal buildings are those of the Government, the Mint, and the Church of the Matriz, which is said to be, next to the Cathedral of Lima, the finest ecclesiastical edifice in S. America.

Pot-Pourri (Fr.), in perfumery signifies a mixture of dried flowers and crushed spices, placed in a vase for the purpose of diffusing a fragrant odour through a room. P.-P. also denotes a medley of music, and a mess of meat and vegetables; in the latter signification P.-P. is synonymous with the Scotch *hotch-potch*.

Pots'dam, capital of the Prussian province of Brandenburg, is beautifully situated at the influx of the Nuthe into the Havel, on the Potsdamer Werder, an island formed by the Havel (which here expands into a series of lakes), and surrounded by woody hills, 16 miles S.W. of Berlin by rail. It is divided into the old and new towns, has five suburbs, and is partly fortified with ramparts. The Brandenburg Thor is a fine triumphal arch, designed from that of Trajan at Rome. The Havel and canal are crossed by seven bridges. The streets of P. are broad and straight, and are adorned with many splendid buildings. Of the squares, the finest are the Wilhelms-Platz, in which is a statue of Friedrich Wilhelm III., the Lustgarten, serving as a military parade ground, with fourteen bronze busts by Rauch, of York, Blucher, Alexander I. of Russia, &c.; and the Altmärkt, in the midst of which is an obelisk of red and white marble 80 feet high, with medallion busts of the Great Elector and the first three kings of Prussia. The principal building is the royal palace, built 1660-1701, and forming an oblong parallelogram with a colonnade 370 feet long. The rooms of Friedrich the Great are preserved in their original condition, and contain numerous interesting relics. Other buildings are the Rathhaus, erected by Friedrich II. in 1754; the military orphan asylum, 426 feet long, in four stories, with a tower 158 feet high; the opera-house; and the hussars' barracks. The Garnisonkirche has a fine chime of bells in a tower 298 feet high, and a marble pulpit, surrounded by trophies captured from the French in 1813-15 and 1870-71, and under which are the graves of Friedrich Wilhelm I. and Friedrich the Great; the church of St. Nicholas, N. of the Palace, erected 1830-37, has an iron cupola 261 feet high, added 1843; and the Friedenskirche, situated at the entrance to the park of Sanssouci, (completed 1850), is in the Basilica style, with a quadrangular entrance-court and detached clock tower. The garden and park of Sanssouci are beautifully laid out, and are noted for their grand trees and maze of delightful walks. Within the park is a fountain which rises to a height of 120 feet, and ascending from it a broad flight of steps 66 feet high, intersected by six terraces, leads to the Palace, built by Friedrich the Great (1745-47), afterwards his principal residence, and in which many relics of him are preserved. To the W. is the Orangery, in the Florentine style, 990 feet long, adorned with many fine marble statues, amongst them one of Friedrich Wilhelm IV., unveiled in 1873. At the back of Sanssouci is the famous Windmill, which the miller refused to sell to Friedrich the Great, and which is still

the property of the miller's descendants. The park is intersected by an avenue a mile in length, at the W. end of which stands the New Palace (1769). A mile to the S.E. is the Charlottenhof, a royal country residence. The Palace of Babelsberg (1835-38), the property of the Emperor Wilhelm, is a picturesque Gothic structure, situated in a beautiful wooded park, overlooking the Glieniker Lake. N. of P., three-quarters of a mile from the Jäger Gate, is the Russian colony of Alexandrowka, founded in 1826, and near it the New Garden with the Marble Palace, founded in 1786, and adorned with frescoes of the Nibelungen Lied. P. has a gymnasium, high school, various special schools, and an institution called the Luisendenkmal for providing a marriage-outfit for poor girls of good character. The manufactures are considerable, and include linen, earthen and zinc wares, veneer, leather, glue, soap, candles, tobacco, sugar, oil, vinegar, beer, and brandy. There is also a Government factory of small arms. Pop. (1875) 45,041; garrison, 7000. P. was a town of the ancient Wends, but owes its importance to the Great Elector. Its modern splendour is due to Friedrich the Great and the succeeding Prussian kings. See Schmidt, *Geschichte und Topographie der Residenzstadt P.* (Potsd. 1825); Griebner, *Wegweiser durch P.* (Berl. 1854).

Potsdam, a town of New York, U.S., on the Racket River, 22 miles E. of Ogdensburg, is noted for the extensive quarries of sandstone of a geological formation which has taken its name from the town. There are in the town six churches, one weekly newspaper, numerous foundries, and manufactories of furniture and agricultural implements. Pop. (1870) 7774.

Pot'stone, a massive schistose rock, composed chiefly of chlorite, with an admixture of quartz, felspar, mica, or talc. The name is derived from its capability of being turned in the lathe and worked into various articles for domestic use.

Pott, August Friedrich, an eminent philologist, born at Nettelrode in Hanover, November 14, 1802. He studied theology and philology at the University of Göttingen (1821-24), was a teacher in the gymnasium of Celle (1825-27), and became a *privatdozent* in the University of Berlin (1830), whence in 1833 he was called to Halle, first as extraordinary, and since 1839 as ordinary professor of comparative philology. Among P.'s works are *Etymologische Forschungen* (2 vols. Lemgo, 1833-36; recast in 3 vols. 1859-71), *De Borussia-Lithuanica tam in Slavica quam Lettica Linguis Principatu* (2 vols. Halle, 1837-41), *Die Zigeuner in Europa und Asien* (2 vols. Halle, 1844-45), *Antikauen oder Mythische Vorstellungen vom Ursprunge der Völker und Sprachen* (Lemgo, 1863), &c. His *Zigeuner*, crowned by the Institute of France, is a monument of German industry, embracing as it does all that was then known concerning the Gypsies, though its author never but once conversed with a member of the race. On December 17, 1869, P. was elected a correspondent of the French Academy of Inscriptions.

Pott'er, Cipriani, an English musician, born in London in 1792, was principal of the Royal Academy of Music from 1832 to 1859. He composed nine symphonies, a number of overtures, the cantata of *Adora e Corado* (1830), several violin quartets, and a great quantity of works for the piano. P. greatly improved the English school of pianoforte playing, and trained many of the most distinguished players and teachers of that instrument. He died September 26, 1871.

Potter, John, born at Wakefield, Yorkshire, in 1674, passed from the free school of his native town to University College, Oxford (1692), and was elected a fellow of Lincoln College (1694). Having taken orders (1697), he became successively chaplain to Archbishop Tenison (1704) and to Queen Anne (1706), Regius Professor of Divinity (1708), Bishop of Oxford (1715), and Archbishop of Canterbury (1737). He died at Lambeth, October 10, 1747. Besides editing Lycophron's *Alexandra* (1697) and the writings of Clemens Alexandrinus (1715), P. was author of *Archæologia Græca*, or *Antiquities of Greece* (2 vols. 1798-99), which was long a standard work, and passed through innumerable editions, and of a *Discourse of Church Government*, and other treatises, collected in his *Theological Works* (3 vols. Oxi. 1753).

Potter, Paul, was born at Enkhuysen in 1625. His father, Peter P., was an artist, and instructed his son so well, that in

his fifteenth year his cattle pieces were sought after. At the age of twenty he went to the Hague, married the beautiful daughter of Balkenende, an architect, and six years later removed to Amsterdam. Many of his best works were executed for Frederic Henry, Prince of Orange. His best pictures are small, exquisite in finish, yet free in handling. A picture of his, representing oxen in a meadow, sold in 1750 for £25, was bought by the Emperor of Russia in 1815 for £900. He produced a few good etchings. P. undermined his health with hard work, and died at Amsterdam, January 15, 1654. See Bartsch, *Le Peintre-Graveur*, vol. i., and Le Carpentier's *P. P.* (1818).

Potter's Clay, a highly plastic variety of clay used in the manufacture of porcelain and Pottery (q. v.). Owing to its containing proportions of lime and oxide of iron it is comparatively fusible, and consequently resolves itself into a slaggy mass at temperatures which vary according to the proportion of these constituents present.

Pottery and Porcelain. Under these terms, which are embraced in the single name Ceramics (Gr. *keramos*, from *keras*, 'a horn,' the material of early drinking vessels), should properly be included all manufactures of baked clay, from the coarsest bricks and tiles, up to the most artistic products of the potter's art. There is really no dividing line or break in the series which may be traced between these extremes, and it is only a matter of convenience to treat of bricks, &c., by themselves as building materials, and include only among pottery vessels non-structural substances and ornamental ware. The potter's art and its products possess supreme historical interest; they occupy an important place from an artistic point of view, and the manufacturing processes connected with them are varied and complex, while in industrial utility pottery is second to no other product of human labour.

History.—That which gives pottery its great historical value is the practically indestructible nature of the material, whereby substances made in the most remote ages show to us their material, design, ornament, and impressed characters almost as when they were newly elaborated. The art of making pottery was certainly among the earliest developments of human industry. Rude vessels of pottery belonging to the stone age of prehistoric times—before the use of any metal was understood—are not uncommon, and it is quite probable that our primitive forefathers understood and practised the art at a time when the mammoth was an inhabitant of Central Europe. The earliest made pottery was certainly very rude in material and workmanship, being simply masses of coarse clay rudely fashioned by the hand and sun-dried. Such pottery, not having undergone the change which results from exposure to a high temperature in kilns, is soft and perishable. Remains of this primitive pottery in the form of urns containing bones, &c., are frequently found in tumuli and the graves of the ancient inhabitants of Britain. Sun-dried pottery was probably long in use before the art of kiln-baking the moulded clay was discovered. Pottery clay, when baked in a furnace, undergoes partial fusion and chemical union of its component elements, whereby it ceases to be affected by water, and cannot again be worked up into a plastic mass, as is the case with merely sun-dried clay. Thus kiln-baked pottery, although it can be broken and crushed to powder, is in itself an imperishable substance; and in other properties, as hardness and closeness of texture, tenacity, and strength of body, the process of hardening by fire constituted an enormous advance on the primitive sun-drying. The introduction of the potter's wheel marked another important era in the progress of the art. When and by what race this notable implement was first used it is impossible to determine; but it was in use among the Egyptians not less than 2500 years before the Christian era. With the help of the wheel, the ancient potters were enabled to mould their pottery with a symmetry of form and an equality of thickness unapproachable by mere hand-moulding. Latest of all the great improvements came the art of glazing and enamelling, or covering the naturally porous body of the P. with a glassy coating of either a transparent or an opaque character. The stages in this important advance are thus excellently epitomised by the learned Dr. Birch:—'The invention of glass has hitherto been generally attributed to the Phœnicians, but opaque glasses or enamels as old as the eighteenth dynasty, and enamelled objects as early as the fourth, have been found in Egypt. The employment of copper to pro-

duce a brilliant blue coloured enamel was very early used both in Babylonia and Assyria; but the use of tin for a white enamel, as recently discovered in the enamelled bricks and vases of Babylonia and Assyria, anticipated by many centuries the rediscovery of that process in Europe in the 15th c., and shows the early application of metallic oxides. This invention apparently remained for many centuries a secret among the Eastern nations only, enamelled terra-cotta and glass forming articles of commercial export from Egypt and Phœnicia to every part of the Mediterranean. Among the Egyptians and Assyrians enamelling was used more frequently than glazing, and their works are consequently a kind of fayence consisting of a loose frit or body, to which an enamel adheres after only a slight fusion. After the fall of the Roman Empire the art of enamelling terra-cotta disappeared among the Arab and Moorish races, who had retained a traditional knowledge of the process. The application of a transparent vitreous coating or glaze over the entire surface, like the varnish of a picture, is also referable to a high antiquity, and was universally adopted, either to enhance the beauty of single colours or to promote the combination of many. Innumerable fragments and remains of glazed vases, fabricated by the Greeks and Romans, not only prove the early use of glazing, but also exhibit in the present day many of the noblest efforts of potters' art.

Artistic Development.—The earliest appearance of ornamentation on pottery consists merely of rude thumb marks and nail scratchings, to which, of course, the plastic substance readily lent itself. These scratchings gradually become more elaborate till they assume the appearance of incised patterns, and at an early stage ornaments in relief appear. A distinct advance in ornamental conception is found in the introduction of coloured ornament, which first appears as simple bands or chequers of brown or dark colour on a white ground. Artistic form in the higher sense is first found in the beautiful vases of the ancient

Greeks, popularly known as Etruscan vases; on those of the best period, between the 6th and 4th centuries, B.C., the figure painting and other ornamentation show the perfection of Greek art. A prodigious number of these, in perfect condition, have been recovered from graves in S. Italy, and from them a flood of light is thrown on the history, dress, habits, and religious practices of the races who made them. From the earliest periods the island of Samos was celebrated for its pottery, and under the Roman Empire a knowledge of its products was not only widely spread throughout Europe, but local manufactories of Samian ware were established at localities widely apart throughout the extended dominions of the empire.

The ware was generally fashioned into bowls, the body being thick

Greek Pottery.

and of a peculiarly rich coralline red colour, and the ornamentation moulded in relief on the lower part of the exterior. A very perfect and characteristic example was found in Glasgow Green in October 1876. It is now preserved in the Kelvingrove Museum, Glasgow.

The art of making porcelain is undoubtedly a Chinese invention, in which country, at a very early date, the manufacture of pottery attained a remarkable development. According to Oriental records, porcelain was first made in China during the Han dynasty, between B.C. 206 and A.D. 87, so that it may be said the manufacture began with the Christian era. For seventeen centuries porcelain continued to be an exclusively Oriental product, and it is not till about the beginning of the 13th c. that we find any record of examples of the manufacture being even seen among Western nations. Oriental decorative ware, while it exhibits the peculiar artistic instincts of the races producing it, served very largely to furnish models for European potters, Delft pottery furnishing a notable example of decoration drawn direct from Chinese ware. The pottery and porcelain of China and Japan are varied in their decorative treatment, different

periods and separate centres of manufacture showing distinctive styles of decoration, so that the classes of ware are more numerous than are those of European nations and periods.

For a period of about one thousand years, corresponding to the so-called dark ages, the making of pottery having any artistic

Majolica.

value was practically extinct in Europe. Early in the 14th c. the Italian pottery now well known as 'Majolica,' from having been originally made in the island of Majorca (known also as Majolica), began to be manufactured, and with the renaissance of art it attained high excellence from a decorative point of view. The distinguishing feature of Majolica is found in the enamel or opaque glaze with which it is covered, being in this respect like the earlier Persian pottery. The manufacture flourished in many of the smaller states of Central Italy from the latter part of the 15th c. well into the 17th, when its products began to be neglected in favour of Oriental porcelain, then introduced into Europe. In the decoration of the earlier specimens bright blues and yellows with iridescent lustre prevail, thereafter comes prevailing yellow tints without iridescence, and mythological subjects, and during the decadence Arabesque scrolls were much employed. In the 16th c. a peculiar variety of stoneware or dense pottery was made in Germany. The leading types were a white ware made into tall cylindrical jugs with raised figures and ornaments, glazed brown jugs or bottles with coats of arms, and grey ware with relief ornaments in blue and marone. In the same century two classes of pottery were produced in France, both of which are of singular artistic interest and value. The first is the enamelled fayence of the famous Bernard Palissy (q. v.) the leading peculiarity of which lies in the marvellous grace and fidelity with which he modelled in full relief upon his dishes the forms and colours of fishes, reptiles, insects, plants, &c. Genuine Palissy ware is very rare and valuable, but much more precious and scarce is the so-called Henri Deux or Oiron ware made about the same period, of which there exists only about eighty specimens. Oiron ware consists of a delicate yellowish glazed body decorated with inlaid ornaments in coloured slip and relief figures, masks, shells, wreaths, &c., in the manner characteristic of renaissance ornamentation.

Porcelain (soft paste—the *pâte tendre* of the French) was first manufactured in Europe in 1580 at Florence under the auspices of Francis I., Grand Duke of Tuscany. The true Oriental porcelain (hard paste), however, was not discovered till about 1715, in which year it was manufactured at Meissen in Saxony by Böttger. Böttger's famous discovery gave an enormous impetus to the art, and notwithstanding the most

strenuous efforts to keep his discovery secret and to confine the manufacture to Dresden, it soon spread to the principal Conti-

Reptile Dish—Pallissy.

mental capitals, in which it was encouraged by the patronage of the ruling princes. In Vienna the manufacture was begun in 1720, Berlin in 1751, and at Sèvres (q. v.) for hard paste in 1759, although there the famous French *pâte tendre* had been manufactured from 1756. Among other famous European centres of manufacture may be enumerated Höchst in Mainz, Fürstenburg in Bavaria, Ludwigsburg or Kruenburg, Venice, and Capo di Monte, near Naples.

In Great Britain the first potter who deserves mention on account of the artistic excellence of his productions is Josiah Wedgwood (born 1730); in his hands British pottery attained an elegance of form, perfection of material, and beauty of ornamentation which neither before nor since have been rivalled. The characteristic production of Wedgwood was his jasper

Wedgwood Vase—Blue Jasper.

ware, a beautiful smooth and delicate biscuit ware, which by the admixture of metallic oxides fired into clear velvety colours formed an admirable surface on which separately moulded white figures and ornaments in relief were attached. The Wedgwood works are still continued at Etruria in Staffordshire by the descendants of Josiah Wedgwood. The manufacture of porcelain (soft paste) was begun in England about 1730 at Chelsea and Stratford le Bow, but hard paste was not made till the Plymouth factory started in 1760. The other centres from which porcelain of artistic worth was sent out in the 18th c. are Derby, Worcester (still continued), Bristol, and Swansea. At the present day the 'potteries' district in Staffordshire is the great centre of artistic and commercial pottery and porcelain, and nowhere in the world are artistic works of a higher class produced than by such firms as Minton's, Copeland's, and Wedgwood's. The Royal Porcelain Works at Worcester also produces porcelain of distinctive character and the highest decorative excellence.

Manufacture.—From what has been already said, it will be obvious that P. and P. may be separated into many classes according to the nature of the paste or materials, the peculiarities of ornamentation, the kind of glazes employed, and their presence or absence, and many other circumstances. The following classification, partly abstracted from Wagner's *Technologie*, embraces the leading distinctive varieties:

I. HARD OR DENSE WARE

- A. Hard porcelain or true china.
- B. Soft or European porcelain.
- C. Biscuit porcelain or Parian.
- D. Stoneware, including ironstone or fine glazed stoneware, salt glazed stoneware, and unglazed jasper and basalt ware of Wedgwood.

II. SOFT OR POROUS WARE.

- a. Fine Fayence with transparent glaze (Delft).
- b. Fayence with enamel or opaque glaze (Majolica).
- c. Common earthenware, glazed (Rustic ware).
- d. Terra-cotta vases, flower-pots, &c.

The materials which are employed in the fabrication of all these classes of ware are clays of varying degrees of fineness and purity of colour, some of which are refractory or fire-resisting in the highest degree, as Kaolin or China clay, while others are more fusible, such as ordinary potter's clay, owing to the presence of lime, oxide of iron, and other similar fluxing agents. To these natural clays are added ground felspar, calcined flints or fine sand, burnt bones and chalk. The dense wares are semifused in burning, and the hard porcelain differs from the others in containing a higher proportion of the infusible Kaolin. It consequently must be submitted to a much higher temperature than the others in order to produce that semi-fusion which yields a dense non-porous body. Fayence or earthenware, although made of fusible materials, is not fired to the fusing point, and consequently is porous in structure; and to render it impervious to liquids, the body must be glazed. The glaze in all cases must be composed of materials which form a glaze at a lower temperature than that required for firing the body, and consequently glazes which may be used for hard porcelain cannot be applied to earthenware. For hard porcelain the glaze employed consists of a mixture of felspar and quartz. Salt is generally employed for glazing common stoneware; while for fine qualities the transparent glaze contains lead and borax. For common earthenware the principal constituent of the transparent glaze is also lead, but in opaque or enamel glazes oxide of tin is added to the lead. These substances, either by themselves or in combination with the siliceous materials of the bodies to which they are applied, all form thin coatings of real glass over the ware, partly penetrating, and always adhering firmly to the body. In the case of hard porcelain, body and glaze are fired in one operation; soft porcelain and earthenware undergo two firings—first, in the biscuit oven, and second, in the gloss or glazing oven; and salt glaze is applied to stoneware by throwing moist salt into the kiln containing the articles at the highest temperature in process of firing.

With the exception of distinctions already alluded to, the operations involved in the manufacture of ware of all kinds are essentially the same. For porcelain and fine ware much care is expended to secure the purity and intimate subdivision of materials employed, and correspondingly less care is required in proportion as the fineness of body becomes an object of less regard. The mechanical processes necessary for the fashioning of the clay vary according to the form and external appearance of the articles to be made. Globular or cylindrical vessels, having a smooth exterior, are worked upon the potter's wheel, which is simply a plane surface or table revolving horizontally. Handles, or other accessories to such an object, however, are formed in moulds made of plaster of Paris, as are also all angular objects, and such articles as are irregular of form or have impressed ornaments. For plates and like articles, cakes or bats of clay rolled out are laid on moulds having the form of the interior of the plate, &c., against which they are pressed by profiles which possess the outline of the exterior of the article. Hard porcelain, after being fashioned, is allowed to remain in the 'green' or unfired state for some time, till a certain amount of its moisture has evaporated. The glaze is then applied, and the articles, protected in seggars or fireclay vessels against direct flame, are placed in the oven. In some cases, porcelain is painted or coloured under the glaze, but more commonly coloured decorations are applied above the glaze, and the colours being mixed with fluxing agents, are burned in upon the glaze, as is also the gilding. The burning in of ornamentation and gilding is effected in a muffle at a much lower temperature than is necessary for body and glaze firing. The great proportion of common earthenware, and sometimes wares of higher quality, are decorated under the glaze by transfer printing. The objects are first fired in the biscuit oven, and in the biscuit or unglazed condition they are extremely porous, and readily absorb any fluid material. The pattern to be impressed in the ware is printed in a suitable medium, according to the colour desired, from a copper plate on a thin tissue paper. The tissue paper, with its newly impressed and wet pattern is applied to the surface of the biscuit ware, to which it adheres, and the porous pottery attracts the wet ink,

and absorbs a sharp, well-defined impression of the pattern. Thereafter the paper is washed off; the article, with the pattern now transferred to it, is dipped in the glazing slip, and thereafter placed in the gloss oven, from whence, after one firing, it is withdrawn a complete decorated and glazed piece of P. The following table shows the chemical composition of typical examples of P. and P. :—

	Chinese Porcelain.	English Porcelain.	Wedgwood Ware.	Lambeth Stoneware.
Silica	71.04	40.60	66.49	74.00
Alumina		24.75	26.00	22.04
Oxide of iron	22.46		6.12	2.00
Lime	3.82	14.22	1.04	0.60
Alkali	2.68		0.20	1.06
Magnesia		0.43	0.15	0.17
Bone-earth and oxide of iron		15.32		
	100.00	100.00	100.00	99.87

The works treating of P. and porcelain are very numerous, but the following are among the most eminent standard authorities: Brogniart's *Traité des Arts Céramiques* (Par. 1844), Marryat's *History of P. and P.* (Lond. 2d. 1857), Jacquemart and Le Beau's *Histoire de la Porcelaine* (Par. 1862), Jacquemart's *Histoire de la Céramique* (Par. 1873, English translation by Mrs. B. Palliser, Lond. 1873), and Chaffers's *Marks and Monograms on P. and P.* (6th ed. Lond. 1878). *The Ceramic Art of Great Britain, from Pre-historic Times down to the Present Day*, by Llewellyn Jewitt (1878), is a work of very high value. Another of unequalled beauty and merit, *Keramic Art of Japan*, by G. A. Audsley and J. L. Bowes of Liverpool, is at present (1878) in course of publication.

Pott'inger, Eldred (Major), the hero of the siege of Herat, was born in 1811 at Mount Pottinger in County Down. At the age of seventeen he went out to Bombay as an artillery cadet. His uncle, Sir Henry P., was Resident in Scinde, and under his patronage he started from Peshawur in 1837 as an independent traveller to penetrate Afghanistan. He adopted the disguise of a *Syud* or holy man, which he did not put off till he had reached Herat, after many risks. This town, then held by an Afghan prince, was forthwith besieged by the Persians, led by the Shah in person, and it held out for almost a year, until relieved by a British diversion in the Persian Gulf. The successful defence is entirely attributed to the exertions and courage of P. As political agent during the disastrous Afghan war of 1841-42, he was compelled to sign the treaty which Lord Ellenborough repudiated. In 1843 he died of fever at Hong-Kong, while on a visit to his uncle, Sir H. P. See *Lives of Indian Officers*, by Sir J. W. Kaye (Lond. 1867).—**Sir Henry P.**, uncle of the preceding, born in 1789, was also a distinguished Indian officer in the political or diplomatic department. For his services in Scinde he received a baronetcy in 1839. He was ambassador to China (1841-42), governor of Hong-Kong (1843-44), of Cape Colony (1846-47), and of Madras (1847-54). P. died at Malta, 18th March 1856.

Pott'o (*Cerculeptes candidivolentulus*), a species of carnivorous quadrupeds formerly classed with the Lemur (q. v.), and inhabiting S. America. It attains the size of a large cat, and is of a light brown colour, its fur being marked with thin dark bands. The tongue is very long and flexible, and is employed in obtaining honey from the nests of wild bees, and in the capture of insects.

Potts'ville, a city of Pennsylvania, U.S., on the N. bank of the Schuylkill River, 93 miles by rail from Philadelphia, is of some importance as the centre of the anthracite coal trade for the Schuylkill district. There are large deposits of iron ore in the neighbourhood, and two shafts were sunk in 1877 to a depth of 1500 feet, in order to reach the underlying coal-vein. P. contains eighteen churches, an opera-house, a free reading-room, two daily and five weekly newspapers. Pop. (1870) 12,384.

Pouch (Fr. *poche*), in military equipment the name given to a strong leather case lined with tin, in which the soldier holds his ammunition. It is carried across the back appended to a belt.

Pouched Rat, a name given to more than one species of Rodent, having cheek-pouches which seem to be used as receptacles for food. The Canada P. R. or Gopher, is a familiar species, attaining a length of 7 or 8 inches. Its fur is of a brownish red colour on the upper parts, and whitish brown below. The cheek-pouches are large. The Fur Country P. R. (*Saccophorus borealis*) is another well-known species. Its length is 10 inches, and its colour a yellowish grey above, and white below. The cheek-pouches are very large.

Poughkeepsie, a city of New York, U.S., on the E. bank of Hudson River, 75 miles N. of New York, and 69 miles S. of Albany by rail. It is one of the most agreeable places of residence in the United States, and is celebrated for the large number of its educational institutions, which include a commercial college. There are in the town twenty churches, a public library, and three daily and five weekly newspapers. The principal manufactures are dyewoods, carpets, pins, iron, and shoes. Pop. (1870) 20,080.

Poulpe (from the Gr. *poulypous*, a form of *polypous*, 'many-footed'), a name restricted in zoology to indicate the *Octopus*, or eight-armed cuttlefish. It has eight feet or arms surrounding the head and mouth, and may be regarded as representing typical species of the group to which it belongs. The P. is a *Dibranchiate*, or two-gilled Cephalopod, and is able to swim backwards through the water by the ejection of the water used in breathing from the anterior funnel or *infundibulum*. Like other *Dibranchiate* cuttlefishes, the P. secretes an inky fluid, which it pours out when irritated or alarmed, and thus darkens the surrounding water. The P. is now successfully kept in large aquaria.

Poultice. See CATAPLASM.

Poul'try (from Fr. *poult*, a 'hen'; Lat. *pullus*, 'a young fowl'), the collective name of the Rasorial and Natatorial birds domesticated by man. Of these, the common fowl, turkey, guinea-fowl, duck, and goose are the species or genera most usually chosen. They are reared not merely for the sake of their flesh but for their eggs—the trade in eggs, indeed, having become well-nigh as important a branch of industry as that in P. itself. The breeding and rearing of P. form a subject of very wide extent, but of somewhat empirical nature. There is no lack of material it is true, but the results and methods of rearing P. have rarely been collated and arranged with the exactitude necessary to bring the results clearly before the mind. Of the so-called 'sitting' fowls, the Cochins-China, Malay, and Dorking breeds are the best known. The Spanish and Hamburg breeds rarely 'sit.' In Britain P.-keeping is generally regarded as a mere accidental appendage to the functions of a farmer. Continental farmers on the contrary find it a profitable enterprise, and give it a much greater amount of attention.

The P.-house should be built of brick or similar material, the floor especially should be hard and easy to clean thoroughly. It should have a special court attached to it, protected by wire-netting, and its floor bricked, whilst feeding-troughs and water-dishes should form part of the furniture. The hatching boxes should be kept separate and distinct from the ordinary living boxes, and special attention to ventilation is as necessary as attention to cleanliness. P. suffer materially when confined in badly-ventilated pens, and the only sure method of preventing them from being infested with parasites is to thoroughly and frequently purify the P.-house. The courtyard itself should possess a shade or covered portion to protect the birds from wet or the heat of the sun.

Regarding the housing together of P., turkeys and geese should be kept separate from hens; ducks and hens agree perfectly; the former of course require frequent access to water. Ducks, in fact, will thrive best if allowed an infinite measure of liberty. Their food consisting largely of worms, &c., is picked up readily in the mud of ponds and brooks; but their wandering habits to some extent interferes with the regular deposition of the eggs. After the young are hatched, the mother and her brood should for some time be shut up at night in a special box or pen. With regard to food, it may be said that there is no more profitable way of disposing of a large proportion of kitchen refuse than in a P.-yard. But in addition, P. require to be fed with corn, bran, and other substances, even

when they have free access to green vegetables and other food. The importance of a constant supply of pure water cannot be over-estimated, and unless P. have access to gravel, for the purpose of obtaining small pebbles to aid the action of the gizzard in triturating the food, they generally fail in health. A due supply of lime is also necessary for P., as affording the materials used in the formation of the shell of the egg, &c. See *The Henwife, her own Experience in her own P.-yard*, by Mrs. Ferguson Blair of Balthayock (Edin. T. C. Jack; 10th ed. 1877).

Pound (Old Eng. *pund*, from *pyndan*, 'to shut in'), in English law, means an enclosure belonging to a parish or manor, in which stray cattle may be legally detained until damage done by them is paid for. *P.-breach* is the offence of liberating cattle lawfully impounded, or of damaging the P. The offender is liable by statute to a penalty of £5. 12 and 13 Vict. c. 92 provides for the punishment of persons assaulting the keeper of a P., and for the recovery of the expense of food given to cattle impounded.

Pound (Old Eng. *pund*; Lat. *pondus*, 'weight'), is a standard unit of mass common to all the western and central states of Europe. It is ordinarily spoken of as a standard measure of weight; but the weight of a pound is strictly the force with which it is attracted towards the earth. The weight varies according to the locality, but the mass is always the same. At present the standard English P. is the mass of a certain piece of platinum, and is equivalent to 7000 grains. It is called the P. avoirdupois to distinguish it from the P. troy, which is equal to 5760 grains. The latter P. is employed exclusively by jewellers and apothecaries. The P. sterling is a coin equal in value to 20 shillings. The name was so applied at a time when 20 shillings were coined out of a P. of silver; and though there are now 66 coins to the P., the name is still retained in its original signification.

Pounder, a technical term used to denote the force of a cannon firing solid shot. Thus we speak of a '100-P. Armstrong gun.'

Poussin, Nicolas, a great French painter, was born near Grand-Andely in Normandy, probably on the 15th June 1593. After studying drawing in his native province, he repaired to Paris in 1612, and after suffering years of obscure misfortune and penury in the prosecution of his art, reached Rome in 1624. Here, having formed a friendly and professional alliance with Du Quesnoy, the sculptor, he devoted himself, in company with that artist, to the study of the ancient statues and bas-reliefs, though even at this time he preserved that loyal devotion to the works of Raphael which he had evinced from an early age. For some years, in spite of most patient and profound study, he was utterly ignored, but gradually friends gathered round him. The earliest and staunchest of these was Cassiano del Pozzo. Cardinal Barberini was his first patron, and his 'Death of Germanicus' and 'The Capture of Jerusalem,' painted for that liberal ecclesiastic, made P.'s reputation. The court of Rome gave him a commission to execute a mosaic of 'The Martyrdom of St. Erasmus' (in the Vatican Museum). It is the only work of P.'s that bears his signature. From 1630 to 1640 P. toiled incessantly in his great vocation. Among the fruits of his noble industry during these ten years are 'The Appearance of the Virgin to St. James the Less,' 'The Triumph of Flora,' 'Camillus handing over the Schoolmaster of Falisci to his Pupils,' 'The Rape of the Sabines,' 'The Manna of the Hebrews,' 'Four Bacchanals,' 'The Striking of the Rock,' 'Rinaldo and Armida,' 'The Passage of the Red Sea,' &c. Louis XIII. invited him to Paris in 1639, and lodged him in the Tuileries, where he painted his great work the 'Last Supper,' but from which, as a result of professional pique, he fled again to Rome in 1642, to return to France no more. He died at Rome, 19th November 1665, after a life of simplicity and devotion to art. P.'s lifelong admiration of Raphael was rewarded with something of the genius and spirit of that great master, and a Raphaelite grace and power mark the forms and expressions of his later works. His spirit is essentially classic, and one fault of his pictures is that they seem in some cases to be painted bas-reliefs—wanting in light and shade. In landscape he is admirable, and he is classed with Salvator as among the earliest great landscape painters. See Eugene Delacroix, *Le P., Moniteur* (1853); E. David, *Discours sur la Vie du P.*; *Lettres de N. P.*; and H. Lemonnier, *Docu-*

ments relatifs a N. P., in the *Annuaire de la Société Philotechnique* (1858).—**Gaspard P.** (properly *Duchet*), brother-in-law of Nicolas P., was of French extraction, but was born in Rome in 1613, studied under his brother-in-law, and achieved the highest reputation as a landscape painter. He is singular as being remarkable at once for fidelity and facility; his foliage is always true to nature, yet he could paint a landscape in a day. His composition is simple and impressive, and his tone usually sombre. He may be studied with advantage in the National Gallery, which contains several of his *chefs d'œuvre*. P. died in 1675.

Povin'dahs, or Bunn'ers. The name of the Lohani traders in N.W. India, mostly in the Punjab district of Bunn, who from time immemorial have had extensive dealings with Bokhara and Central Asia. They are said to number 12,000 fighting men with 60,000 camels, and their trade by the Gomul Pass in Afghanistan amounts to £60,000 a year. They only make one journey in the year, for they have to force their way by fighting or by paying black-mail. They regularly lose a hundred or more men, and about 2 per cent of their beasts. In Afghanistan they pay dues varying from £1 to £9 per camel-load. The P. bring down shawl-wool, raw silk, gold and silver wire, dried fruits and horses; and carry back piece-goods, brocades, metal ware, indigo, spices, tea, gold coin, and gold thread.

Pow'an (*Coregonus cepedei*), a species of Teleostean fishes, allied to the Salmon family, and belonging to the same genus as the Pollan, Vendace, &c. It occurs only in Loch Lomond, in Scotland, and is familiarly named the 'Freshwater Herring.' It may attain a length of 16 inches. The P. is caught in quantities in August and September by means of nets. Its flesh is very palatable.

Powdered, or **Semée**, in heraldry, an epithet applied to a shield bearing any number of small charges exceeding six, scattered over the field, as the ancient shield of France in Westminster Abbey.

Powell, Baden, born at Stamford Hill, near London, August 22, 1796, entered Oriel College, Oxford, and graduated with first-class mathematical honours (1817). He took orders (1820), was presented to the vicarage of Plumstead in Kent (1821), became a F.R.S. (1824), and was appointed Savilian Professor of Geometry (1827). In 1854 he removed from Oxford to London, where he died, June 11, 1860. P. did much to promote the study of physical science at Oxford, and published treatises on the *Differential and Integral Calculus* (1829-30), on *Elementary Optics* (1833), and on the *Undulating Theory of Light* (1841), &c. He was also author of various theological works, all strongly tinged with Rationalism, amongst them being *Religion and Science* (1833), *The Connection of Nature and Divine Truth* (1838), *Christianity without Judaism*, and *On the Study and Evidences of Christianity*, the last one of the famous *Essays and Reviews* (1860).

Power, in law, means an authority given to some one to do an act which, without the authority, he would not be entitled to do. When given to an agent, the writing and authority which it conveys are called a P., or Letter, of Attorney (q. v. under LETTER). The similar term of Scotch law is *Faculty*, which is also a term of English law (see FACULTY). Applied to the disposition of property, as leases, portions, &c., a P. may be either given or reserved, and the possessor is called the donee. The doctrine of *powers* comprehends the most technical and abstruse part of the law of property.

Powers, Hiram, an American sculptor, was born at Woodstock, Vermont, U.S., 29th July 1805. The son of a small farmer, he had received but a scanty education when he was obliged to provide for himself. He went to Cincinnati, where he was successively employed in a hotel, a store, and a clock-maker's shop. While in this latter situation he became acquainted with a Prussian sculptor, who was engaged at the time on a bust of General Jackson, and got from him some lessons in modelling. In this he made such rapid progress that he soon felt he had found his proper vocation. After some years' employment at the Cincinnati Museum, he went to Washington in 1835, and passed two years there in making busts of various eminent personages. The liberality of a patron, Mr. Longworth, enabled him to carry out a design he had long

cherished of visiting Italy. In 1837 he went to Florence, where he produced in the following year his statue 'Eve.' This was followed by the 'Greek Slave,' the best known and most admired of all his works. It was exhibited in the London Exhibition of 1851, and gained for P. a place in the foremost rank of living sculptors. Among his other works may be mentioned 'Il Penseroso,' 'The Fisher Boy,' 'California,' 'America,' statues of Washington and Calhoun, and busts of Marshall, Adams, Webster, Van Buren, and others. P. died 27th June 1873.

Poyning's Law, or Statute of Drogheda, passed in 1495, provides that all Acts then or lately passed in England concerning its common weal should be effectual in Ireland. It further provided that no parliament should be held in Ireland until the Lord-Lieutenant had certified to the English crown the cause for holding it, and licence had been given by the sovereign. P. L. was repealed, and the Irish Parliament emancipated, in 1783.

Pozzo di Borgo, Carlo Andrea, born at Alala, in Corsica, May 8, 1764, studied at the University of Pisa, became an advocate, and hailing the outbreak of the Revolution, sat for Ajaccio in the French National Assembly (1791-92). He returned to Corsica to attach himself to the party of Paoli, and on that leader's fall (1796) withdrew to London, and thence to Vienna (1798). Animated by a fierce hostility to the house of Bonaparte, P. next entered the service of the Emperor Alexander (1803), was a zealous promoter of the Russo-Austrian coalition terminated by Austerlitz (1805), and after the peace of Tilsit was again compelled to take refuge in Austria (1809-10). With the catastrophe of 1812 commenced the most important period of his diplomatic career. He urged Alexander to a continuance of the war, won over Bernadotte, opposed all overtures of peace that might prove favourable to Napoleon, and was appointed Russian ambassador to the court of Louis XVIII., sitting in this capacity at the Vienna Congress. After the battle of Waterloo, in which he received a wound, P. resumed his post of ambassador at Paris (1816-32), there doing all he could to dissuade the Bourbons from their reactionary policy, was created a Russian count (1826), and transferred to London (1834). In 1839 he retired into private life at Paris, where he died, February 15, 1842. See Vuhner, *Notice Biographique sur le Comte Pozzo di Borgo* (Par. 1842).

Pozzuola'sna, a pulverulent volcanic product, originally obtained near Pozzuoli (q. v.), in the vicinity of Mount Vesuvius, and now procured from other European localities, enters, with rich lime, into the composition of some hydraulic mortars. It is mainly composed of burnt silica and alumina, which eminently fit it for mortar-making. P. may be made artificially from sand, clay, lime, and iron oxide. P. was employed by the Romans for mortar, and Smeaton first used it in England in the construction of the Eddystone lighthouse.

Pozzuoli, a town of S. Italy, province of Naples, 6 miles W. of the city of that name, situated on a projecting hill and at its base, overlooking the bay of P., which forms part of the Gulf of Naples. Although no longer a place of importance, it is intensely interesting on account of its marvellous vicissitudes, and its memorials are full of singular interest alike to the historian, the artist, and the student of natural phenomena. It was founded at an early period by the Greeks, and called by them *Dicalarchia*, a name changed to *Puteoli* by the Romans, who subdued the place in the Samnite wars. It repulsed Hannibal in 214 B.C., and subsequently became the chief Roman commercial city. As the principal depôt for the trade with Egypt and the East, it received Oriental forms of worship, and St. Paul spent seven days here (Acts xxviii.). Destroyed by Alaric, Genserich, and Totila, P. was rebuilt by the Byzantine Greeks, but the work of devastation was completed by earthquakes and volcanic eruptions. The ruined temple of Serapis (an Egyptian god) consists of a square court enclosed by 48 massive marble and granite columns, with 32 small chambers adjoining. The portico rested on six Corinthian columns (three of which remain), bearing a rich frieze, while in the interior of the court there stood a circular temple, and here were founded the statues of Serapis, now in the Naples Museum, and two inscriptions, which mention the restoration of the temple by Marcus Aurelius and Septimus Severus. The lower parts of

the ruin were long under water, and interesting observations have here been made of the various changes in the level of the sea. The Amphitheatre, which affords a clear idea of the design and arrangements of such structures, has an arena 369 feet long by 216 broad, which could be laid under water for the representation of naval combats. Other remains are those of the so-called Temple of Neptune, a few pillars rising from the sea, of the sea-covered Temple of the Nymphs, from which have been recovered a number of columns and sculptures, and of the Puteolaneum, the delightful villa of Cicero. Of the ancient pier of 25 buttresses, which supported 24 arches, 16 are left, 3 being under water. They are constructed of bricks and puzzolana earth, and bear an inscription recording that the pier was restored by Antoninus Pius. A common but mistaken belief is that they were connected with the bridge of boats which Caligula threw across the bay of Baize. The Solfatara (*Forum Vulcani*), near P., is the crater of an extinct volcano, an oblong space, enclosed by hills of pumice stone, from fissures in which ascend vapours and sulphurous gases. The only eruption of lava on record was in 1198. A stucco factory is now established here. To the E. are the white hills (*Colles Lencogei*), whose light-coloured dust was so prized by the ancients for tinting groats and other kinds of grain. Several streamlets which contain alum, and are used for cutaneous diseases, rise here, and fall steaming into a ravine near the Lago d'Agnano. The inhabitants, employed in soap and cement making and fishing, numbered in 1874, 11,751.

Prac'tice is an arithmetical method which aims at simplifying the process of compound multiplication. It is a growth of the British system of coinage, and could have no existence under a truly decimal system. The method is explained in all English text-books on arithmetic.

Praed, Winthrop Mackworth, a kinsman on his mother's side of the 'Father of Massachusetts,' was born in London, July 26, 1802, and sent in his ninth year to Langley Broom School, near Colnbrook. Thence he passed to Eton (1814), where his career was singularly brilliant, his editorship of the *Etonian* (1820-21) revealing to Charles Knight, its publisher, 'an unbounded fertility of mind and readiness of resources.' Entering Trinity College, Cambridge (1821), he gained six university medals for Greek and English verse, came out third in the classical tripos (1825), and was elected fellow of his college (1827). At Cambridge, with Macaulay, Moultrie, and Sidney Walker, he wrote for Knight's *Quarterly* (1822-23), and during a residence at Eton as tutor to the Marquis of Ailesbury's son (1825-27) had the chief management of the short-lived *Brasen Head*. In 1829 he was called to the bar at the Middle Temple, and travelled the Norfolk circuit with high success; but a seat in Parliament had always been his ambition, and in 1830 he stood for St. Germans as a Conservative, he and Macaulay having changed places in politics since the days when they debated at the Cambridge Union. This borough was disenfranchised two years later, and P. afterwards sat for Yarmouth and Aylesbury, in 1834 filling the post of secretary to the Board of Control. His parliamentary career was hardly equal to the expectations formed of him, and its possibilities were closed by his early death, July 15, 1839. P.'s mock heroics, charades, *vers-de-société*, and political pasquinades, many of which appeared in the *Literary Souvenir*, are admirable in their kind, sparkling with subtle wit and polished sarcasm, while their freedom from the least taint of bitterness reflects the lovable nature of their author. Some of them were collected and reprinted at New York in 1844 and 1859, but the first complete edition is that published at London (2 vols. 1864), with a Memoir prefixed by Derwent Coleridge.

Præfect (Lat. *præfectus*), the title of various officers and magistrates in ancient Rome. The most important were:—(1) *Præfectus urbi*, the warden of the city, who possessed the imperium in the city in the absence of the consuls. The office, which had become superfluous by the appointment of the *prætor urbanus*, was revived by Augustus with greatly extended powers and the entire control of the police department. (2) *Præfectus prætorio*, who commanded the imperial bodyguard; (3) *Præfectus annonæ*, an extraordinary magistracy for the distribution of public charity in times of scarcity; (4) *Præfectus aquarum*, the superintendent of the water supply; (5) *Præfectus ararii*,

custodian of the treasury; (6) *Præfectus vigilum*, captain of the night watch.

Præsumptio, in English Law, is an offence of a kind tending to promote Papal power, in diminution of that of the crown. It subjects the offender to forfeiture of estate, and to confinement during the will of the sovereign. Many statutes regarding P. are repealed, and prosecutions under it are now unheard of. There is only one instance of a prosecution in the *State Trials*. In that case the punishment of P. was inflicted on some persons for refusing to take the oath of allegiance to Charles II.

Prænestæ. See PALESTRINA.

Prætor (Lat. from *præire*, 'to go before'), at first the title of the Roman consuls as leaders of the state army, became a special official designation in 366 B.C., when, to indemnify the Patricians for the admission of the Plebeians to the consulship, it was decreed that a third officer should be elected from among the Patricians, in the *Comitia Centuriata*, immediately after the consular election. Not till 337 B.C. was there a Plebeian P. The P.'s functions were mainly judicial, and to the edicts of the successive prætors is mainly due the splendid development of the Roman law. Sometimes the P. led the state army, and during the absence of the consuls with their armies acted for them in the city. The P., originally a consul of the year before, was styled *Collega Consulibus*, was a curule magistrate, possessed imperium, and was attended by six lictors, though later by only two. Subsequently, the consuls were chosen from among the ex-prætors. In 246 a second P. was appointed to give judgment in suits between Romans and resident aliens, hence called *Peregrinus*, the original P., who retained only cases exclusively Roman, being styled *P. Urbanus*. In 227, two prætors were added for the administration of Sicily and Sardinia, two more for the Spanish provinces in 197, two more by Sulla, while Julius Caesar raised the number successively to ten, twelve, fourteen, and sixteen. Augustus fixed it at twelve, but Tiberius had sixteen, and Pomponius speaks of eighteen under Nerva. The *P. Urbanus*, the first in rank, could never leave the city for more than ten days at a time, and besides his judicial functions, superintended the Ludi Apollinares. Those prætors who held office in the city were often at the end of the year sent to rule provinces with the title of Proprætor or Proconsul (q. v.). The prætorian provinces were fixed by the senate and distributed among the prætors by lot.

Prætorian Bands, or *Co'horts*, were a body of Roman troops distinguished from the rest by double pay and superior privileges. Originally they were simply the select guard of a general in battle; but Augustus constituted them a special order. In his time there were nine cohorts (each consisting of a thousand men, horse and foot), three in Rome, and the others distributed throughout the principal towns of Italy. They were composed of picked soldiers from the old Umbrian, Etrurian, and other colonies. Tiberius recalled those in the country and assembled them in a permanent camp at Rome, increasing their number and entirely changing their discipline. The officer who commanded them was called the prætorian prefect; and in the days of military despotism this prefect wielded almost imperial power. The prætorians served for sixteen years; the private soldiers ranked equally with centurions of the common army, and on retirement received 20,000 sesterces each. This celebrated band in later times degenerated into a company of robbers, who had to be bribed into peace by all political candidates for the empire. In 193 A.D. they actually sold the 'purple' to Didius Julianus; but in the same year Severus deprived them of their privileges. In 312 Constantine disbanded them.

Pra'ga, a suburb of Warsaw (q. v.).

Pragmatic Sanction or Rescript, a solemn decree promulgated by the supreme head of a state, is a term derived from the Byzantine court. In European history it is applied to (1) the ordinance by which Charles VII. of France, in 1438, secured the liberties of the Gallican Church (q. v.); (2) the instrument by which Karl VI., Emperor of Germany, vested in 1713 the Austrian succession in his male or (failing such) his female descendants, with reversion to his brother Joseph (see MARIA THERESA); and (3) to the law of inheritance by which Carlos III. of Spain abdicated the throne of the Two Sicilies in favour of his third son and his descendants (1750).

Prague (Czech *Praha*, Ger. *Prag*), the capital of Bohemia, and one of the most picturesque and interesting cities of Europe, is magnificently situated on the Moldau, 118 miles S. by E. of Dresden by rail. The Moldau here curves to the E., and the main part of the city, including the Altstadt, Neustadt, and Judenstadt, lies on the level right bank, while the Kleinseite and Hradschin (palace district) are built on the steep, hilly W. bank. The river contains several beautiful islets (the Sophien and Schützen being great public resorts), and is crossed by some nine bridges, of which the most celebrated is the Karlsbrücke (1357-1507), with sixteen arches, and a span of 540 yards. The buttresses are adorned with thirty statues and groups of saints, and a slab of marble on the coping marks the spot where John of Nepomuk, the patron saint of Bohemia, is said to have been cast into the river by order of the Emperor Wenzel in 1383. According to the legend, the saint floated on the Moldau, while over his head shone five brilliant stars. The Franz-Josephs-Brücke, leading to the grand new promenade on the left bank, was opened in 1868. Both parts of the city are girt with walls and bastions, and the citadel (*Wyssehrad*) in the extreme S., occupying the ancient castle of Libussa, is strengthened with modern fortifications. P. has many fine mediæval buildings, and its seventy-seven towers and its monuments give it a singularly imposing appearance. On the E. bank are the Gothic Rathhaus, erected 1838-48 on the site of an old building, of which the chapel and great tower of 1474 (with a curious clock) still remain; the Teynkirche, the old church of the Hussites of the 15th c., in which Georg Podiebrad was crowned in 1458, and which contains the statues of Cyril and Methodius, the apostles of Bohemia, the tomb of Tycho Brahe, &c.; the Rathhaus of the Neustadt (1370, greatly altered in 1806), the storming of which by the mob under Ziska began the Hussite wars in 1419; and the old palace of the Nostitz family, now the Bohemian National Museum, comprising a library with MSS. of Ziska, Huss, &c., art collections, and antiquities. In the Jews' quarter, or Judenstadt, at the turn of the Moldau, are nine synagogues, the most interesting, the Altneuschule, a Gothic structure, dating from the beginning of the 13th c. On the high W. bank are the Jesuit church of St. Nicholas (1722), rich in gilding and marble; the cathedral of St. Vitus (begun 1344, repaired 1874), with a tower 323 feet high, the tombs of many Bohemian kings and several emperors, frescoes by the early P. school (Thomas of Mutina, Theodor of P.), &c.; the Burg or imperial palace, founded by Karl IV. in the style of the Louvre, and completed by Maria Theresa; the rich abbey of Strahow (Premonstratensian), on the highest site in P., containing among other pictures a valuable work painted by Dürer in 1506; the pilgrim chapel of St. Loreto, an exact imitation of the famous Italian Casa Santa; the Palace of Count Nostitz, with its rare collection of statues and casts, and about 400 pictures; and Count Czernin's palace, one of the largest in Germany, now used as barracks. The university, the oldest in Germany, was founded in 1348, and in the 15th c. attracted students from all parts of Europe. It has now (1878) 123 instructors, 1780 students, and a library of 130,000 vols. and 7762 MSS., rich in Czech literature. There are many benevolent and educational foundations, a German and a Bohemian theatre, and fine public gardens. Carolinenthal in the N.E. and Smichow in the S.W. are busy industrial suburbs, the former intersected by a railway viaduct two-thirds of a mile long. The centre of Bohemian commerce, P. manufactures cottons, linens, leather, hosiery, Bohemian glass, machinery, &c. Pop. (1870) 157,275, of whom four-sevenths are Bohemian, three-sevenths German, and 13,000 Jews. P. is said to have been founded by Libussa, first Duchess of Bohemia, in 722. The prosperity of its university was checked by the attempt of Wenzel to limit the privileges of foreign students, a measure which led to the founding of universities at Leipsic, Rostock, Cracow, &c. P. is famed in history as the sphere of action of Huss (q. v.) and Jerome (q. v.), the great heralds of the Reformation, and as the earliest stronghold of Protestantism in Germany. It suffered much from the Hussites under Ziska (q. v.), especially in 1424, and in 1620, soon after the opening of the Thirty Years' War, the victory of the Catholic League over Friedrich V., the Elector Palatine, on the White Hill (Weisse Berg, $\frac{1}{2}$ of a mile W.), sealed the doom of Protestantism in Bohemia. During the Seven Years' War, P. was taken by Friedrich the Great in 1744, but his troops were expelled in the same year. The 'Battle of P.' was a victory of Friedrich

over the Austrians, 6th May 1757. The Austrian troops suppressed a rising here in 1848. The treaty of P. settled the terms of peace between Austria and Prussia, 23d August 1866. See Tomek's *Geschichte der Stadt* (Prag, 1865), *Geschichte der Universität* (1849), and Ambro's *Der Dom zu P.* (1859).

Prahran, a suburb of Melbourne, on the S.E. side of that city, but forming a distinct municipality. It contains several important educational and charitable institutions, and a town-hall which is a prominent landmark for miles around. Pop. (1875) 16,309.

Prairie (Fr. *prairie*, 'meadowland,' from *pré*, 'a meadow') is a term used to denote any large expanse of grass-covered country without trees. There is much prairie-land in different parts of the world. In Europe a large portion of the Russian steppes, in Asia the greater part of Southern Siberia, in S. America the *llanos* bordering the Orinoco and the *pampas* of Buenos Ayres come under this definition. The term is, however, practically limited to the great central plains of N. America, covering an area of 400,000 sq. miles, and including Western Ohio, Southern Michigan, Wisconsin, and Minnesota, and the whole States of Indiana, Illinois, Missouri, Arkansas, Iowa, and Kansas, along with the territories of Nebraska and Dakota. These plains are sometimes flat, but generally undulating, of rich and fine soil, and drained by the great navigable rivers Ohio, Mississippi, and Missouri. They are rapidly being opened up by the spread of railroads, and already bear large crops of wheat and maize. Their indigenous animals—the buffalo, antelope, P.-hen, P.-dog, &c.—are fast dying out along with the Indian tribes. The absence of trees, except in the river-beds, has been attributed to the fineness of the soil, but is more probably due to climatic reasons, such as the smallness of the average rainfall, together with the periodical P.-fires. In several parts of the prairies remains of cities and fortifications have been discovered, which seem to indicate that the Indians who held them when first invaded by Europeans had themselves dispossessed a more highly civilised race.

Prairie-Dog (*Spermophilus Ludovicianus*), a species of Marmot (q. v.) or Rodent, found in the prairie-lands of N. America, especially near the Missouri and its tributaries. It occurs in the prairies (whence its name), and lives in burrows. The association of the rattlesnake and a species of burrowing owl (*Athene cucularia*) with the P.-D. does not appear to be other than accidental. The owl appears to establish itself in the disused burrows. The average length of the P.-D. is 16 inches. It has a short tail and cheek pouches. The incisor teeth are large and protrusive. The body is reddish-brown above and white below; grey and black tints mingling with the red of the upper parts. Prairie-dogs do not appear to hibernate. They are exceedingly lively creatures, and gambol in front of their burrows, frequently sitting at rest on a little mound of earth placed in front of the entrance to their home. On the slightest alarm, they enter their habitations and disappear from sight as if by magic.

Pra'krit ('natural,' 'vulgar'), the name given to the group of Indian languages which are immediately derived from the Sanskrit. Properly speaking, the modern vernaculars now used ought not to be included, the term being strictly confined to those dialects, of various degrees of degradation, which can still be plainly recognised as of pure Sanskrit origin. In classical literature the P. is used by the subordinate personages in the dramas, and is found in the oldest inscriptions. See *Institutiones Lingua Pracritica*, by Lassen (Bonn, 1837), and *An Introduction to the P. of the Sanskrit Dramas*, by E. B. Cowell, Professor of Sanskrit in the University of Cambridge (1875). The term *prakriti*, derived from the same root, is used in the Sankhya philosophy for the evolver, the primal cause of all existence.

Prase (Gr. *prason*, 'a leek'), a variety of chalcedony possessing a dark green colour due to the presence of copper. It occurs in the iron mines of Breitenbrunn, Saxony, and, in fine crystals, in the Cedar Mountains, Cape Colony. The *prasius* of the ancients was a pale leek-green stone, and was extensively engraved for signets.

Pra'ti, Giovanni, an Italian poet, born at Dascindo, near Trent, January 27, 1815, studied jurisprudence in the University of Padua, and in 1841 published the sorrowful love-poem *La Edmenegard*, which won so wide a popularity that its author resolved henceforth to devote himself entirely to the Muse.

Early inspired by the vision of a united Italy, he nevertheless incurred the suspicion of his countrymen by his devotion to the House of Savoy, and on the outbreak of the Revolution of 1848 was hunted from Padua to Venice, and from Florence to Turin. In 1849 P. was appointed *Poeta Cesareo* to Charles Albert; in 1862 he was elected a deputy in the Italian Parliament. Of late years he has resided at Rome. P.'s earlier romantic and political poems are infinitely superior to his later productions, in which he seeks to develop a mystic philosophy, though both are marked by a grace of thought and diction which go far to make up for a lack of spontaneity and original conception. To the former class belong *Canti Lirici*, *Canti per il Popolo*, and *Ballate* (1843), *Memorie e Lacrime* (1844), and *Passegiate Solitarie* (1847); to the latter, the epics *Rodolfo* (1855), *Il Conte Riga* (1856), and *Ariberto* (1860). A complete edition of his works appeared at Milan (1862). See Marchese, *Le Pote P.* in the *Revue des Deux Mondes* (March 1856).

Pratique (Fr.; Ital. *pratica*, Span. *practica*), a term used chiefly in the S. of Europe to denote the limited quarantine which the captain of a ship is held to have performed when he has proved to the authorities of a port that his vessel is free from infection.

Prato ('the meadow'), a town of Italy, province of Florence, 10 miles N.W. of the city of Florence, lies in a fertile plain on the right bank of the Bisenzio, and is a station on the Florence and Pistoja Railway. It has an ancient citadel, a magnificent cathedral, manufactures of straw-plait, silk, and woollen fabrics, and important publishing works. Pop. (1874) 39,594.

Prawn (*Pakemon*), the name of various species of *Decapodous* Crustaceans allied to the lobsters and crabs. The prawns are distinguished by a long *rostrum* or beak projecting from the front of the *carapace* or shell. The legs are well developed, the second pair being the most powerful, and the inner pair of antennæ having three divisions. The common P. (*P. serratus*), familiar on the British coasts, is a table delicacy. The flesh is much more palatable than that of the shrimp. The body is almost transparent, and has various tints and markings of orange and purple. The shell, like that of the lobster, turns red and opaque after boiling. Other species of P. belong to the genus *Hippolyte*. Of these, the best known is White's *Æsop* P. (*H. Whitei*); the Ring Horned P. is the *Pandalus annulicornis*, distinguished by the curvature upwards of the rostrum or beak.

Praxiteles, whom we know chiefly from the writings of Pliny and Pausanias, was a famous sculptor, and the founder of a school of sculpture in Greece in the 4th c. B.C. He is said to have commenced his artistic career in 364-360, and to have practised it to an extreme old age. He worked both in bronze and marble, but was more successful, more splendid in the latter material (*P. marmore felicitior et clarior fuit.*—Plin.). Of many of his works we know nothing save from the descriptions of ancient writers, but they appear to have been in the highest style of art for beauty of form and vivacity of expression. An ancient copy of his 'Apollo the Lizard-Killer' is regarded as one of the treasures of the Vatican. Lucien states that his 'Venus of Crinolus' was the finest of his works. It was destroyed by fire at Constantinople in the 5th c., and its loss is regarded as one of the most deplorable sustained by art. The 'Bacchanalian Dance,' one of his masterpieces, together with other distinctive specimens of his work, is in the National Gallery. Poliorcetes, besieging Rhodes, where the treasure was, withheld his hand, lest in destroying the city he should also destroy this triumph of genius. Other works were the 'Nausicaa,' and the 'Paralus,' the latter a human figure, classed by Cicero among the most famous statues and pictures. P., whose nature was of a sunnier and more joyous character than that of Phidias, eschewed the grave subjects and the severe heroic forms in which his predecessor delighted. His art was liberal, luxurious; expressing itself in rich, if also somewhat effeminate forms of beauty.

Prayer (Fr. *prêre*, from Lat. *precatio*) is the expression of the feelings implied by Religion (q. v.), which is the due apprehension of the character of God, and of our relation to him as our Creator, Preserver, and Redeemer: reverence and love for his divine perfection, gratitude for his mercies, penitence for sins, hope in his forgiving love, and desire for his favour and the blessings needed for ourselves and others. It assumes (1) the personality of God, (2) that he is near us,

and both able and willing to hold intercourse with us; and, (3) that he has the personal control of things out of himself. It thus appears that people's notions of the efficacy of P. will depend on their notions of God; and accordingly various theories on the subject might be enumerated. 1. That of the Peculiar People, who are the only consistent believers in the supernatural efficacy of P. to accomplish physical as well as mental and moral effects, and who, trusting entirely to the divine action, seek the aid of no human means, *e.g.*, medical skill to help the recovery of the sick. 2. That of those who use the proper human means along with P.: the one extreme of this theory being that God answers P. by natural means appointed for this purpose from the beginning, and that the P. and its answer were in the counsel of God, and if there had not been the one there would not have been the other; the other extreme, that the human means alone may be effectual, but that P. may assist, *e.g.*, the recovery of a sick person, by exciting his faith and hope. 3. That of those who, 'knowing the intelligent order that pervades the universe, believe in it, and, with true filial piety, would never suggest a petition for a change in the Great Will, as touching any childish whim of their own.' Of those who hold this last theory, some (1) believe that P. is entirely useless. (2) Others, admitting that it is so in the domain of natural phenomena, which are regulated by inviolable laws, hold that in the mental and moral universe there is conscious disorder which is a proof of the need and reasonableness of interference with it; otherwise, that the Mind and the Will may be influenced by P., through a direct action of the divine upon the human spirit. (3) And still another class hold the only effect of P. to be its reflex action on ourselves; a theory which has been held by some along with the belief in a personal deity (*cf.* Blair's *Sermon on James i. 17*, and a sermon by Dr. Leechman, Glasgow, 1744). But those who hold the theory in modern times generally regard the Deity as the infinite personification of our purest ideal, and P. as a yearning of the human spirit after that ideal. See Hodge's *Syst. Theol.* (Edinb. 1873), *Contemp. Rev.* (October 1872, January 1873, October 1876).

P. for the dead was practised in the Christian Church from the earliest times, having been probably practised among the Jews (*cf.* 2 Macc. xii. 43-45, Matt. xii. 32). It was common in the 2d c., and in the 4th c. it was reckoned a heresy to deny its efficacy. The reasons for the practice were various. See PURGATORY.

Pre-Adamites, the name of a supposed race of human beings who inhabited the earth prior to the creation of Adam. This theory, which gave rise to a short controversy in the Reformed Church in the 17th c., was started by Isaac Peyrerius, who was at first a Protestant, but died a Roman Catholic priest, and who published a work, *Preadamitæ* (1655), to prove from the *Epistle to the Romans* (v. 12-14) the existence of men in the world before Adam.

Prebend (Lat. *præbenda*, 'fuel and salt furnished to a royal envoy'), in canon law, is a stated income derived from some fixed source. Generally it is the right of receiving certain revenues for the performance of certain duties in a cathedral or collegiate church, the right to a stall in choir, and a vote in chapter. A P. may be held by a layman, and took its origin in the 11th c., when the commune formerly devoted to the support of the bishop and chapter was divided in equal portions among the latter. The holder of a P. is called a prebendary. See Blunt's *Dict. of Doct. and Hist. Theol.* (Lond. 1872).

Precedence, the order of general and social rank admitted on public occasions and in society. A table of P. both for men and women will be found in Burke's *Peerage*, where peers and baronets are numbered also with regard to their P. A particular place on the scale is an honour derived from the Crown or Parliament, or confirmed by authorised and ancient custom. The leading authorities are the statute 31 Henry VIII., the 'Act for placing the Lords,' which was of the nature of a declaration confirming ancient and pre-existing usage in the marshalling of dignities, an 'Order of all Estates of Nobles and Gentry of England' having been framed in 1339; the statute 1 Edw. VI. c. 7, s. 3, which enumerates the then names of dignity thus—duke, archbishop, marquis, earl, viscount, baron, bishop, knight, justice of either bench, or serjeant-at-law. Letters patent 9, 10, and 14 James I., which *inter alia* decided that younger sons of viscounts and barons should take P. of baronets; 1 Will. and Mary, c. 21; and the Acts of Union, 5 Anne, c. 8, and 39 and

40 Geo. III. c. 67, which defined the order of the various classes of peers thus—(1) Peers of England, (2) peers of Scotland, (3) peers of Great Britain, (4) peers of Ireland, and (5) peers of the United Kingdom. The sovereign ranks first, the Prince of Wales and the princes of the blood-royal next. The place after the sovereign's relatives is assigned to the Archbishop of Canterbury, the Lord High Chancellor, and the Archbishop of York, in order. Various high dignitaries of the Crown precede and intersperse the order of dukes, marquises, earls, viscounts, bishops, barons, judges, baronets, knights, &c. The eldest sons of peers of one rank come in P. after the peers of the next rank, the younger sons after the peers of the second following rank. A similar precedence exists among ladies, the P. of the husband being that which is regarded, except when the daughter of a peer marries a commoner, when she retains her rank by right of birth. The wives and children of great officers of state, however, have no P. on account of that official rank alone. Widows of peers married to commoners retain their old P. by courtesy. The daughters of peers, &c., rank in order after the wives of their eldest brothers. Dowager peeresses rank before the wives of existing peers. It is a leading principle of the law of P. that P. emanates from the father or husband, and cannot be derived from a female except in the case of a peeress in her own right. Thus the daughter of a duke confers no P. upon her son any more than the daughter of a citizen. Baronets, whether of England, Scotland, Great Britain, Ireland, or the United Kingdom, take P. according to the dates of their patents. Ambassadors yield P. only to the members of the royal family of the court to which they are accredited, and to the sons and brothers of crowned heads. Foreign ministers and envoys are assigned places in this country between dukes and marquises, although it was settled at the Congress of Vienna that they had no real claim to P. Lord-lieutenants and high-sheriffs of counties have no P. from these offices. The clergy, the bar, the army, navy, and other classes have amongst themselves a certain P. and relative rank, which gives them, however, no position on the general or social scale. The question of P. of the great officers of state of Scotland and Ireland with reference to similar officers of England has never yet been definitely settled. At the coronation of William IV. the Lord Chancellor of Ireland was placed next to the Lord Chancellor of Great Britain. The members of the College of Arms, who are the council of the Earl Marshal of England, are usually referred to on questions of P., and have charge of the arrangement of processions on state occasions. The Lyon Court is the authority in Scotland.

Precentor (Lat. *præcentor*), an officer in a cathedral. In cathedrals of old foundation the P., who ranked next in order to the dean, was intrusted with the charge of the inferior clergy and of the choir, and with other important duties. In modern cathedrals the dignity is held by a minor canon, who regulates the musical services. In monasteries, the P. is the monk who presides over the conduct of the service, keeps the books, sends out the briefs, and settles the prayers to be said for departed brethren. The leader of the psalmody in Presbyterian churches is called a P.

Precept, a term of Scotch law denoting an order to some one to do some legal act. Thus a P. of arrestment is a warrant by a judge to an officer of court to arrest the person named in the writing.

Precession of the Equinoxes is an astronomical phenomenon which is a dynamical consequence of the fact that the earth is not a true sphere. It is known that the earth's axis of rotation is inclined to the plane of the earth's orbit; and accordingly the great circles in which the equatorial plane and the orbital plane may be supposed to cut the sphere of the heavens must intersect in two definite points, which are called the equinoxes. These great circles are called respectively the celestial equator and the ecliptic; and their poles are separated by an arc which is equal to the angle contained by these two intersecting planes. Looked at in the direction in which the pole of the ecliptic lies, *i.e.*, from the same side on which the celestial N. pole is, the circumsolar motion of the earth is in the positive direction, is in other words contrary to the motion of the hands of a watch. Now the phenomena of P. consists of a slow negative rotation of the equinoxes round the ecliptic. This necessarily requires the revolution of the

pole of the equator round the pole of the ecliptic, so that the earth's axis describes a cone whose axis passes through the pole of the ecliptic. The revolution is accomplished in 25,800 years; or, the equinoxes have a mean annual retrogression of 50".2. For this reason Aries, the first sign of the zodiac, no longer coincides with the constellation of the same name. The true explanation of P. was given by Newton, who accounted for it by the action of the sun and moon upon that portion of the earth's mass which, owing to its spheroidal state, bulges out beyond the inscribed sphere. If the earth did not rotate about its axis, this action would bring the equatorial plane and the plane of the ecliptic into coincidence; but since rotation exists, the dynamical effect is the continual shifting of the line of intersection of these two planes. If the sun alone acted, the curve of precession would be an accurate ellipse. The action of the moon, however, modifies this in a peculiar way, so that the curve becomes a wavy ellipse. This secondary variation, which has a period of nineteen years, was discovered by Bradley, who called it Nutation (q. v.). The cause of P. is dynamically the same as the cause of the motion of the moon's nodes. See LUNAR THEORY and PERTURBATIONS.

Precious Stones. By this term, which is sometimes used as a synonym for jewel stones, is properly understood those ornamental stones that are found in comparatively large masses, and possess in a modified degree only the fire or lustre, hardness, transparency, and other characteristics for which the real jewels are so highly esteemed. Thus while the term *jewels* comprises the diamond, sapphire, ruby, spinelle, emerald, beryl, topaz, zircon, garnet, chrysoberyl, &c., the name P. S. is held to embrace amethyst, opal, agate, carnelian, jasper, rock crystal, malachite, lapis lazuli, &c.

Precipitation, in Chemistry, is the separation in the solid form of some compound from what was at first a solution. As a general rule most soluble salts are more soluble in hot than in cold water. Consequently P. often results from boiling the solution so as to evaporate it and render what remains stronger, and then letting it cool, when crystals of the salt crystallise out. Natural evaporation, by diminishing the quantity of the solvent, frequently leads to a like P. Again, it is well known that different salts differ widely as to their solubilities, some being quite insoluble in water; and it is a recognised truth in analysis, that if two saline solutions be mixed, double decomposition always takes place, if by the mutual actions of the two salts a less soluble salt than either results. This less soluble salt frequently appears as a precipitate, and it is upon the nature of the precipitates formed by the action of a known agent upon a given salt that the rules of chemical analysis are based.

Precoognition, a term of Scotch criminal law denoting the examination of witnesses under superintendence of the Procurator Fiscal (q. v.) when a crime has been committed. The object is that the public prosecutor may have full information to enable him to frame the charge and carry on the prosecution.

Predestination is a theological term which is used in several somewhat different senses:—(1) In the general sense of foreordination, having equal reference to all events; (2) as referring to the general purpose of redemption, without regard to individuals; (3) to express the purpose of God in relation to the salvation of particular men, including the election of some to be saved and the leaving of the rest to perish. According to Calvinistic theology, the Decrees of God (q. v.) are—1. All reducible to one purpose, *i. e.*, out of the series of possible events God determined on the actual occurrence of the existing order from the beginning of time to all eternity. 2. They are eternal, so that history in all its details is but the evolution of the eternal purposes of God. 3. They are free, in respect of being founded on sufficient reasons, of being formed purely on the council of his own will, or of being absolute, or in no case conditional. 4. They render certain the occurrence of what he decrees. 5. They relate to all events, necessary or contingent, good or bad. With special reference to redemption, P. includes—(1) God's purpose to create the universe; (2) after Adam, by his fall, had brought all his posterity into a state of condemnation, the election of a certain number to eternal life and the leaving of the rest to perish; and (3) the complete salvation of all those whom he has thus chosen to life, for whom Christ specially died, and in whose behalf the certain efficacy

and saving power of the Holy Spirit is exercised. See Hodge's *Syst. Theol.* (Edinb. 1873).

Predicables (Lat. *predicabilia*), in Logic, the kinds of terms or attributes always *predicable* of any subject. They are five in number, *viz.*, genus, species, difference, property, and accident. See Mill's *Logic*, Book i. chap. vii.

Predicate. See PROPOSITION.

Pre-existence is a theory regarding the origin of the soul, in contradistinction to other two theories:—(1) That the soul of the child is derived from the parent as much as the body—a theory (called Traducianism, from the phrase *per traducem*, 'by transmission') which was held by Tertullian (q. v.); and (2) that it owes its existence in each individual to the direct creative power of God (Creationism). According to the Platonic philosophy, the ideas that constitute the essence and life of all external things have been eternally in the divine mind; but Origen (q. v.) went much further, in declaring that the souls of men have a separate, conscious, personal existence in a previous state. Creationism was from the first the orthodox doctrine of the Eastern Church, and subsequently of the Western as well. The Protestants generally adhered to this view, although most of the Lutheran divines of the 17th c. adopted Traducianism, which has found numerous able advocates in modern times, especially in Germany, where the theory of P. has also been revived. See J. Müller's *Christl. Lehre v. d. Sünde* (Eng. trans. Edinb. 1856).

Préfet, in France, is the name of various state officials, who are so called because their duties in some degree resemble those of the Roman *Præfex* (q. v.). The officials to whom the name of P., without any distinctive office, is usually applied, are the *Préfets des Départements*. The old *Maitres des Requêtes*, subsequently called *Intendants*, exercised control of the administration in the provinces, till the country was divided into departments at the Revolution. In 1800 they were replaced by *préfets*, whose principal functions are to give local effect to government measures, to superintend the election of deputies, and to appoint *sous-préfets* over *arrondissements* and other officers, and who have power on occasion to declare a state of siege, and call out the military. They are, however, responsible to a kind of appeal court, called the *Conseil de la Préfecture*. In 1878 there were 86 such *préfets* in France, and 3 in Algeria. In addition, there is a *P. de Police*, and at the head of each of the five *divisions maritimes* into which France is now portioned, there is a vice-admiral bearing the title of *P. Maritime*.

Pre'gel, an important navigable river in the province of E. Prussia, formed near Insterburg by the confluence of the Pissa and Angeraff, flows in a westerly direction, and after passing Königsberg enters the Frische Haff, while it communicates with the more northerly Kuische Haff by the canal of the Deime. It is 120 miles long, and 720 feet broad at Königsberg, and its chief affluents are the Alle from the S. and Inster from the N. Below Tausien the stream divides into two channels, the Old and New P., which after a nearly parallel course of 18 miles, unite again at Königsberg, and thus enclose a long strip of land nowhere more than 3 miles wide. The valley of the P. is traversed by the Southern Railway of E. Prussia, which brings to Königsberg vast quantities of grain and timber from Russia.

Pregnancy. Concealment of. If a child be found dead, and its mother has concealed her pregnancy, the legal presumption is that she has murdered it. The burden of proving that it was born dead or died from natural causes is thrown on her.

Prehn'ite is a member of the zeolite group of minerals which includes all the hydrated double silicates containing no magnesium, or, at most, a very small quantity. P. is a double silicate of calcium and aluminium combined with one molecule of water. It is almost always found associated with calcite, so that it is probably formed in the presence of an excess of lime, being like all zeolites a hydrated felspar.

Prel'ate (Lat. *prælatus*, 'one set over'), means an ecclesiastic having jurisdiction over other ecclesiastics, and was primarily and properly applied to bishops, who in the primitive church received various titles of honour, as princes of the Church, presidents, inspectors, chief-priests, popes, &c. But in the ordinary sense, the superior of a religious order, an archdean, &c., is also a P.

Prell'er, Friedrich, a German painter, was born at Eisenach, 25th April 1804, and educated at Weimar, Dresden, and Antwerp. He resided from 1827 to 1831 at Rome, whence he returned in the latter year to become a professor at Weimar. Among the chief works of P., who excelled equally as a landscape and historical painter, are the series of mural paintings from the *Odyssey* in the museum at Weimar, the landscapes from Wieland's *Oberon* in the 'Wielandzimmer' of the grand-ducal palace of Weimar, and his sixteen cartoons from the *Odyssey* in the museum at Leipsic (reproduced by M. Jordan, Leips. 1875, and chromo-lithographed by Steinbock, Mun. 1876 *et seq.*). P. produced another series of forty illustrations to the *Odyssey* (engraved on wood by Brend'amour and Oertel; 2d ed. Leips. 1873), and more recently a series of similar cartoon illustrations to the *Iliad*. He died in April 1878.—**Ludwig P.**, born at Hamburg, 15th September 1809, after studying (from 1828) philology at Leipsic, Berlin, and Göttingen, settled first (1833) as a 'privat-docent' at Kiel, then as a professor at Dorpat (1838-43), and in 1844 became professor at the University of Jena. Appointed in 1847 chief librarian at Weimar, he travelled in 1852 through Greece and Asia Minor, and died at Weimar, 21st June 1861. P.'s chief works are *Demeter und Persephone* (Hamb. 1837); *Griechische Mythologie* (3d ed. by Plew, 2 vols. Berl. 1872-75); *Römische Mythologie* (2d ed. Berl. 1865); *Historia Philosophia Græca et Romana*, which he wrote in conjunction with Ritter (5th ed. by Teichmüller, Gotha, 1875); and *Aufsätze aus dem Gebiet der klassischen Alterthumswissenschaft* (edited by R. Köhler, Berl. 1864).

Prelude (Lat. *præludo*, 'I play before'), a movement played as an introduction to the performance of a musical work. It is usually written in the same key with the piece which follows.

Premises, is an English law term denoting 'that part in the beginning of a deed, the office of which is to express the grantor and grantee, and the land or thing granted.' It is further said that no person not named in the P. can take anything by the deed, though he be afterwards named in the *habendum*. In Scotch law, the word P. is applied generally to the subject-matter of a deed, and sometimes it is used to signify the lands or houses which are the subject of the right or conveyance. The name is said to have been given from the circumstance of the subject-matter being first described in full, and afterwards referred to as the P. (Lat. *præmissa*, 'things mentioned before').

Premiss is a proposition *going before* a conclusion. A regular syllogism consists of two premisses and a conclusion. The two premisses are sometimes called antecedents, while the conclusion is called the consequent.

Premium Pudicitie is a consideration given to a previously chaste woman by the man who has seduced her. Equity will enforce payment of the bond. But the law distinguishes between an obligation for consideration *passed* and consideration *in future*. A bond for passed cohabitation is good; but one to live in a future state of concubinage is void. Regard is also had to the previous character of the woman in whose favour the bond is given.

Premonstratensians, or **Norbertine Monks**, were a religious order which was founded (1121) by Norbert, Archbishop of Magdeburg, at Prémontré (Isle de France), with the object of re-establishing the obsolete discipline of the regular canons. The rule which Norbert gave to the order was that of St. Augustine, with some slight alterations, and the addition of certain severe laws. By the sobriety of their life and manners, their learning, and cultivation of the useful arts, the P. soon became extremely popular, and spread over Europe. But, just as with the other orders, popularity brought them favour and riches, and riches brought in their train arrogance, luxury, and vice. At first so poor that their only property was an ass which carried the wood which they cut daily and sold for their subsistence, they soon received many donations, and in thirty years they had 100 abbeys in France and Germany. In course of time, in all parts of Christendom they had 1000 abbeys, 500 nunneries, and 300 provostships, besides a large number of priories. The P. came to England in 1146, where they were known from their habit as the White Canons, and where in the reign of Edward I. they had 27 monasteries. They had 6 in Scotland—at Stranraer,

Holywood, Whithorn, Tongland, Dryburgh, and Ferne (Ross), and several in Ireland. See Helyot's *Histoire des Ordres Monastiques* (Par. 1714).

Prenzlau (Ger. *Prenslau*), a town of Prussia, province of Brandenburg, lies on the Uker, where it flows into the Ukersee. It has a fine Gothic church (Marienkirche) of the 14th c., foundries, machine factories, and spinning mills. Pop. (1875) 15,731.

Preposition (Lat. *præpositio*, from *præ*, 'before,' and *ponere*, 'to place') is usually defined, in accordance with its etymology, as 'a word placed before a noun or a pronoun to show its relation to some other word in the sentence.' But it can easily be shown that such a definition is not sufficiently precise. A conjunction, for example, may express a relation between two words in the same sentence. The etymology itself is defective. A P. is not always 'placed before' the word whose relation it fixes; sometimes, even frequently, it comes after it. Innumerable attempts have been made by grammarians to give a more exact expression to the notion of a P. Most of these are failures. The least unsatisfactory is that of Mason:—'Prepositions are words placed before substantives, by means of which we show the relation in which things and their actions and attributes stand to other things.' Or, better still, 'Prepositions are words used to mark or determine the relations in which things and their actions and attributes stand to other things.' In the sentence 'I heard a foot on the stair,' 'on' is a word marking a relation of place between 'stair' and 'foot.' Again, in the sentence, 'I looked in his face,' 'in' marks the same relation between 'face' and the 'act of looking.' The principal relations which a P. marks are those of place, time, and causality. It is an almost universal practice of English grammarians to say that the P. governs the 'objective case.' Nothing can be more erroneous. To speak of 'case' here is absurd, but it is doubly absurd to employ the term 'objective,' which has no meaning except in connection with a transitive verb. In English parsing, pupils should be taught to exercise their intelligence in discovering the actual relations marked or determined by every P., and should not be taught to repeat a phrase into which it is impossible to import a vestige of intelligibility. See Bain's *Companion to the Higher English Grammar* (Lond. 1874), and Mason's *English Grammar* (19th ed. 1877).

Prerogative Court, was the court in England in which wills were proved and administrations taken out. In 1858 its functions were transferred to the *Probate Court* (q. v.).

Presburg (Mag. *Pozsony*, Slav. *Presburek*, Lat. *Posonium*), a town of Hungary, beautifully situated on the Danube, and on the spurs of the Little Carpathians, 41 miles E.S.E. of Vienna by rail. It consists of the inner town, Altstadt, the walls of which were demolished in 1778; the Ferdinandstadt and Neustadt on the N.; the Franz-Josephstadt on the Danube; and the Theresienstadt, Schlossberg (the Jews' quarter), and Zuckermande on the W. The town lies on the N. bank of the river, which is crossed by a fine bridge of boats. The principal buildings are the Gothic cathedral of St. Martin—the former coronation-church of the kings of Hungary—begun in 1090, completed in 1452, restored 1865-67; the Landhaus, in which the imperial diets were held 1802-48, but which is now a court of justice; the Rathhaus; the Franciscan church, founded in 1293; and the Primatial-Gebäude, the winter palace of the Primate of Hungary. Besides those already named, P. has 23 other churches, a theatre, Natural History museum, several academies and high schools, an hospital, and a library of 50,000 volumes. On the Schlossberg, a plateau 273 feet above the Danube, stand the ruins of the royal palace, burned in 1811, and never restored. The industries of P. are important, and include silk-spinning and weaving, tobacco, leather, sugar, paper, and glass manufacture; while there is considerable transit trade in corn, wine, flour, fruit, rosoglio, chemicals, and timber. Pop. (1870) 46,540 (one-fourth Magyars, one-third Protestants, 7000 Jews). P. became the capital of Hungary in 1446, when the Turks had obtained possession of Ofen, but in 1784 the government was carried back to Ofen by Joseph II. A treaty was signed at P. in 1805, after the battle of Austerlitz, by which Venice and the Tyrol were ceded to France. See *Führer durch P.* (Presb. 1862); *P. und seine Umgebungen* (Presb. 1865).

Presbyo'pia, a term used in ophthalmic science to denote long-sightedness. The opposite condition of vision is termed *Myopia*, or short-sightedness.

Presbyte'rianism. Presbyter (Gr. *presbyteros*, 'elder') was a title for the rulers of the Church, borrowed from the Jews, and indicative rather of the wisdom than the age of the person. Presbyterians hold it to be synonymous with Bishop (q. v.). Episcopalians, on the other hand, maintain that presbyters or priests were from the first an order distinct from and inferior to the bishops, who were the successors of the apostles. However this may be, it is a fact that in the 3d c. there were three orders of clergy in the Church—deacons, presbyters, and bishops, and that the Church was finally organised on the principle of Episcopacy.

The distinctive tenets of P. are chiefly two:—1. It differs from Episcopacy (1) in having lay elders ordained, with equal powers to rule (hence called 'ruling' elders) with those of the ministers or teaching elders; and (2) in placing all its Church rulers on the same footing of rank or dignity. It is maintained that there is a distinction made in the New Testament between the two classes of elders—teaching and ruling (cf. Rom. xii. 8; 1 Cor. xii. 28; 1 Tim. v. 17), and that there is no ground in it for the threefold ministry of Episcopacy. The nature of the office of Deacon (q. v.) is held to be defined by the account of its institution in Acts vi., and hence the duties of deacons are confined to the oversight of the poor, and of the outward business of the house of God, while the titles of bishop and presbyter are regarded as equivalent (cf. Acts xx. 17, 28; Phil. i. 1; Tit. i. 5-7; Tim. iii. 1). 2. P. differs from Congregationalism (q. v.), which makes each worshipping assembly independent, by carrying out to the widest limits the principle of subordination and centralisation. There is a kirk-session in every parish, consisting of the minister and a body of lay elders. The ministers within a certain district, with one ruling elder from each session, constitute a Presbytery. Professors of divinity within the same district, if they be ministers, are also members. Several neighbouring presbyteries again combine to form a Synod, in which all the members of the included presbyteries may meet. The highest court is the General Assembly, the members of which are representative ministers and ruling elders from each presbytery, in proportion to the numbers in each. The country in which P. has always had the strongest hold, being the only one in which it has been the national form of Church government from the Reformation, is Scotland. Accordingly the history of P. in that country is the history of the Established Church, with its various offshoots. See SCOTLAND, CHURCH OF; FREE CHURCH OF SCOTLAND; REFORMED PRESBYTERIANS; UNITED PRESBYTERIANS.

Presbyte'rian Church—1. *In the Colonies.*—Canada.—Every shade of Presbyterianism which has prevailed in the mother country has had its representatives in this colony, but the different branches have been at length united. A union took place between the United Presbyterians and the Free Church in 1861, and in 1875 between this united Church and the branch in connection with the Church of Scotland. In 1877 the Presbyterian population was 600,000, the number of congregations 1008, and of ministers 733.

Australia.—The history of Presbyterianism in this colony is almost the same as in Canada. The different branches identified with the Church of Scotland, the United Presbyterian, and the Free Church were united—in Victoria, 1859, Queensland, 1863, New South Wales and South Australia, 1865. The total number of parishes or charges in Australia in 1877 was 278, and of ministers 262; and in all the British Colonies, including South Africa (the P. C. of which has had a connection with Holland, France, and Scotland) and New Zealand, the same year, 1641 charges and 1291 ministers.

2. *On the Continent of Europe.*—The following are the statistics for the various countries in 1877, Germany being omitted because the form of government of the Reformed Church in that country is only partially Presbyterian:—

	Par.	Min.		Par.	Min.
Switzerland	808	1038	Italy—Vaudois	56	56
France—Reformed Ch.	540	595	Free Italian		9
Union of Free Chs	46	46	Hungary	2007	2017
Holland	1309	1583	Bohemia and Moravia	68	67
Belgium	13	15	Russia	40	40
Christian Mission			Spain	12	12
Church	34	18	Norway	3	3
210					

3. *In England.*—The history of Presbyterianism in England begins with Wiclif (q. v.) and the Lollards (q. v.), who in the 14th and 15th centuries rejected episcopal authority. An attempt was made by some of the Puritans of the 16th c. to model the Church of England on that of Geneva. The first separate congregation of Presbyterians was formed at Wandsworth, near London, 1572, but no great number of congregations existed till the Civil War (1642). The system was established under the Commonwealth, but had to give place to Episcopacy again at the Restoration (1660). The organisation and discipline of Presbyterianism were never very stringent in this country, and laxity of doctrine prevailed to such an extent that in the 18th c. it drifted bodily into Unitarianism. A few congregations only remained in the northern counties, between whom, under the title of 'The Synod of the P. C. in England,' and the Church of Scotland there was an unsuccessful attempt to form a union in 1836. A union was formed in 1876 with about an equal number of United Presbyterians, and in 1877 the Church comprised 43,434 enrolled members, in 258 congregations, and 10 presbyteries. Of Welsh Calvinistic Methodists (q. v.) there were in 1875, 1098 congregations, with 522 ministers, in 24 presbyteries.

4. *In Ireland.*—Presbyterianism first obtained a permanent footing in Ireland in 1642 among the Scotchmen who had previously settled in the country. After the Restoration (1660) the Church suffered much persecution, which came to an end at the Revolution (1688). The Regium Donum (q. v.), a grant of £600 which had been given by Charles I., was now doubled, and in 1719 the protection of the Toleration Act (q. v.) was obtained. As in England, Unitarianism began to prevail about the end of the 17th c., and led to a schism (1726). A party who opposed subscription to the Westminster Confession formed themselves into the Presbytery of Antrim, and the more orthodox party remained as the Synod of Ulster. A union was formed in 1840 between this latter body and the Secession Church, which had been founded about a century before by Scotch seceders. The united body, which assumed the title of 'The General Assembly of the P. C. in Ireland,' reckoned in 1877, 560 congregations, 600 ministers, 37 presbyteries, and 5 synods. The Reformed P. C., which was founded in Ireland in 1763, had about 5500 members in 41 congregations, with 31 ministers.

5. *In the United States.*—1. *Of promiscuous origin.*—(1) The first congregation of English-speaking Presbyterians in America of which we know was formed in Maryland by a minister of the Irish P. C., who came from Barbadoes in 1684. In 1705 a presbytery was formed, and in 1716 the Church assumed the title of 'The Synod of Philadelphia.' The adoption by the Church in 1729 of the Westminster Confession, and the revival produced by Whitfield, led to a disruption in 1741, and the formation of the *old side* Synod of Philadelphia and the *new side* Synod of New York, which, however, reunited in 1758. In 1766 they entered into friendly relations with the Congregationalists, but, although a 'Plan of Union' was adopted in 1801, the two Churches never amalgamated. The Plan was abrogated in 1837, and in 1838 the Church itself, owing chiefly to disagreements on this subject, was divided into the Old and New School Presbyterian Churches; but the two were reunited in 1869. This is the P. C. in the United States of America (North). (2) The P. C. in the United States (South) was formed by the withdrawal from the Old School Church of all the congregations in the Southern States on the outbreak of the Civil War in 1861, to which acceded in 1867 the Synods of Kentucky and Missouri, and part of the Presbytery of Chesapeake.

11. *Of Continental origin.*—(1) A branch of the Reformed Church was founded by the Dutch emigrants who settled on the Hudson in 1619, which, however, remained dependent on the Church of the home country till 1771. In 1785 it assumed the title of 'The Synod of the Dutch Reformed Churches,' from which the prefix *Dutch* was dropped in 1867. The Huguenots established churches in the country shortly after 1685. (2) The Reformed German Church was founded in the beginning of the last century by Palatines, Huguenots, and some Swiss. III. *Of Scotch origin.*—(1) A branch of the Associate Church was founded by Scotch emigrants who sympathised with the seceders of 1733. This Church, which was organised in 1754 as 'The Associate Presbytery of Pennsylvania,' united in 1782 with the Reformed P. C., the united body taking the name of the Associate Reformed Church. In 1858 another union took place with the Associate Church, which had grown out of a minority which stood aloof

from the union of 1782, the name now adopted being the United P. C. of N. America. The Associate Reformed Synod of the South was formed in 1821 by the Synod of the Carolinas separating itself from the Associate Reformed Church. (2) The Reformed P. C., which had been formed by Scotch and Irish emigrants, and organised as an independent presbytery in 1774, united with the Associate Church in 1782; but a minority, who refused to accede, got ministers to form a presbytery in 1792, which was organised into a Synod in 1809. A minority, who held it to be right to act as citizens of the States, seceded in 1833, and formed the General Synod of the Reformed P. C., being popularly known as the New Light Covenanting Church. The following statistics are for 1877:—

	Charges.	Ministers.
P. C. (North)	5077	4744
" (South)	1821	1004
Reformed German	1347	650
Reformed Dutch	506	546
United Presbyterian	783	640
Reformed Presbyterian	104	100
General Synod of Reformed P.	55	24
Associate Reformed Synod of the South	100	80
Welsh Calvinist Methodists	..	76

See *Report of the Pan-Presbyterian Council* held in Edinburgh in 1877. See PRESBYTERIANISM.

Presbytes, a genus of *Catarrhine* or Old World monkeys, represented by the Simpai of Sumatra (*P. melalophos*), or Black Crested monkey; by the Entellus (*P. or Semnopithecus entellus*), and by the Proboscis monkey (*P. larvatus* or *Kahau*). In these monkeys the cheek-pouches are rudimentary, the thumbs short, and the tail may exceed the body in length.

Prescot ('the priest's cot'), a town of England, in Lancashire, 8 miles E. of Liverpool, and 2 miles from the Rainhill station of the London and North-Western Railway. It has important manufactures of watch movements, tools, and files, and in or about the town are extensive cotton and flax mills, breweries, drain-pipe works, potteries, and coal mines. Pop. (1871) 5990.

Prescott, William Hickling, D.C.L., an American historian, was born at Salem, Massachusetts, 4th May 1796. He was descended from an old Massachusetts family, his grandfather, Colonel William Prescott, having been an officer in the Revolution. P. received his early education at Boston, where his father held a distinguished position as a lawyer, and entered Harvard College in 1811, with the intention of following the same profession. He graduated in 1814. An accident during his college course deprived him of the use of one of his eyes, and his intense application having greatly impaired the other, he was forced to abandon all idea of becoming a lawyer, and spent the next two years in travelling through England, France, and Italy. On returning to America he married, and commenced a systematic study of history, contributing at the same time some papers to the *North American Review*. Finally he resolved to devote himself to Spanish history, and his friendship with Mr. Everett, then United States Ambassador at Madrid, enabled him to acquire a unique collection of original MSS. and rare books bearing upon the events of the period he had chosen for investigation. Supplementing his defective vision by the constant use of a reader and secretary, and working in the most rigidly methodical way, he got through an amount of work which is astonishing, even if we take no account of the disadvantages under which he laboured. In 1833 appeared his *History of the Reign of Ferdinand and Isabella the Catholic* (3 vols.), which was received with great applause both in Europe and America, and was translated into French, Spanish, and German. After six additional years of labour, he published his *History of the Conquest of Mexico, with a Preliminary View of the Ancient Mexican Civilisation, and the Life of the Conqueror Hernando Cortez* (3 vols. 1843), which was followed by the *History of the Conquest of Peru, with a Preliminary View of the Civilisation of the Incas* (2 vols. 1847), *History of the Reign of Philip II., King of Spain* (vols. i. and ii. 1855, vol. iii. 1858), a work which P.'s death prevented him from completing; and an edition of Robertson's *History of the Reign of Charles V.* (1856), with notes, and an account of the Emperor's life after his abdication. P. was a member of most of the learned societies of Europe, and had the degree D.C.L. conferred on him by Oxford in 1850. He died at Boston, January 28, 1859.

P.'s works rank as standard authorities on the periods of which they treat, a position to which they are entitled not more by the large amount of original information which they contain, than by the fair and judicious spirit which has reduced that information to an historical form. There is a certain easy and picturesque elegance in the language, but it lacks force, brilliancy, and beauty. P. was not a great historical genius, but he was a great student; and his writings show how much can be achieved by patient and intelligent labour. A cheap edition of P.'s historical works was issued by Routledge (4 vols. 1866). A new edition of his complete works, superintended by his last secretary, John Foster Kirk, was published at Philadelphia in 15 vols. (1874-75). See *Life of W. H. P.*, by George Ticknor (1864).

Prescription, in law. A right may be acquired or lost by P. By 3 and 4 Will. IV. c. 27, no person shall make an entry or distress, or bring an action to recover any land or rent, unless within twenty years after the time at which the right to make the entry or distress or to bring the action accrued. In case of tenants at will, the right of action may accrue at the end of the tenancy, or at the end of one year from its beginning, at which time the tenancy is supposed to finish; but no mortgagee or *Cestui que Trust* (q. v.) is within the clause. Money charged on land or rent must be claimed within twenty years. No arrears of rent or of interest arising from money charged upon or payable out of land or rent, or in respect of any legacy, is recoverable after six years from the date of falling due. (See IMMEMORIAL USAGE; LIMITATIONS, STATUTE OF; MERCANTILE LAW AMENDMENT ACT; EASEMENT.) In Scotland, P. is divided into *positive* and *negative*, the former being a mode of acquiring property, or rather of protecting the right from challenge on account of the possessor having continued his possession for the period which bars challenge; the latter, which is the converse of the former, is the loss of a right from not having used it for a certain length of time. Forty years' uninterrupted possession of heritage bars challenge. The statute (Scotch) of 1617 enacts that all actions competent by law upon heritable bonds, reversions, contracts, &c., shall, unless under special circumstances stated in the Act, be begun within forty years from the date of the same. There are also what are called the lesser prescriptions. The decennial P. is in favour of tutors and curators, limiting the right of the pupil or ward to call them legally to account to ten years after the expiration of the office. The sexennial P. limits the right of action on bills of exchange and promissory notes, except bank-notes, to six years from their date. The Act 1579 enacts a triennial P. with regard to tradesmen's accounts, servants wages, and similar debts.

Prescription, in medicine, is the term applied to the written direction or receipt of a medical practitioner to be given to the chemist for the preparation of a medicinal substance. The P. may be for an official compound, the formulæ for which are contained in the British Pharmacopœia, and are therefore supposed to be kept in preparation by all dispensing chemists, or for an extemporaneous compound devised specially for the patient under treatment.

Dr. Paris lays down *five objects* which the physician should have in view in the construction of an extemporaneous formula or P. They are—(1) To promote the action of the principal medicine, or, as he terms it, the basis of a formula; (2) To correct the operation of the basis; (3) To obtain the joint operation of two or more medicines which act in totally different ways; (4) To obtain a new and active remedy not afforded by any single substance; (5) To select an eligible form. The first object may be attained by combining different preparations of the same substance, as a tincture with an infusion; or by combining different substances having a similar action; but in all such cases care must be taken not to prescribe incompatibles. The second object is to render certain medicinal substances more agreeable in their action by adding a corrective: thus by adding a due proportion of the extract of hyoscyamus to the extract of colocynth, the griping tendency of the latter is obviated without interfering with its purgative action. The third object is to act upon a diseased part by the administration of medicines which, when administered separately, act in different modes; thus, in certain cases of dropsy, which is a mere symptom, cathartics and diuretics may be combined, and by such means the symptoms may be more effectually removed than by either the one or the other administered separately. The fourth object

is usually attained by extemporaneous chemical decomposition ; thus by prescribing perchloride of mercury with iodide of potassium, biniodide of mercury is formed ; or an action may be produced by two medicines prescribed simultaneously different from what would be produced by either when taken singly, or within a short interval of each other. The physiological effect of Dover's powder, a mixture of opium and ipecacuanha, is very different from that of either one or other taken separately. The fifth object is to present the medicine in an agreeable form, so as not to cause nausea. This is certainly one of the most important objects to be had in view, for there is no reason why a medicine should be given in a nauseous form, more particularly to children. The active ingredients of many medicines can be given in small bulk, in the form of pills, and the pills may be coated and thus rendered tasteless. Castor-oil and codliver-oil, the taste of which is repugnant to many, may be given in the form of emulsion, and so rendered almost tasteless. It was formerly the custom to write elaborate prescriptions containing an immense number of different ingredients, but medicinal compounds are not now generally so complicated. It is the custom to write out prescriptions in Latin, but many physicians have adopted the practice of writing out the directions in plain English.

Presentation, the name given to the act by which the patron of a living in the Established Church of Scotland appointed a minister. The name has fallen into disuse through the abolition of Patronage (q. v.).

Presentment is the notice taken by a grand jury of any offence, from their own knowledge, without any bill of indictment laid before them. There may be the P. of a nuisance or a libel, upon which the officer of the court must afterwards frame an indictment, when the party presented against can be put on trial.

Preserves for game has no privileges beyond other private grounds, the occupiers of which may hinder others from sporting in them, unless there is a right of chase or free warren. If any one enter on the ground of another he is a trespasser, and if he refuse to go away, he may be forcibly ejected.

Preserved Food. The subject of the preservation of food is one of great and increasing interest in a country like Great Britain, whose native food resources are quite inadequate to meet the wants of the population. It is of almost equal importance in colonies and foreign states capable of producing food much in excess of the necessities of their inhabitants, and wherever distant markets must be resorted to for the disposal of surplus produce. With many and most important food products no difficulty arises, as cereals, starches, sugar, spices, and other substances can be conveyed to and used in all parts of the world in as good a condition as in the regions of their production. But there are numerous important products which undergo putrefactive changes with such rapidity that unless their tendency to change is counteracted by artificial means they are only available as food within a limited time after their collection or preparation. The substances which thus demand some means of artificial preparation are succulent vegetables and fruits, and all kinds of animal food. The latter is by far the most important section, and as regards vegetable products it may be sufficient to remark that the physical conditions which tend to preserve animal substances are generally applicable to vegetable products, while 'preserves' of fruits boiled with sugar are universally known as jams, jellies, or candied fruits.

The trade in P. F. is not of recent origin, but within the past few years it has rapidly attained great dimensions and importance. The number of schemes propounded and patents secured for food preservation are almost countless ; but hitherto comparatively few and simple processes have been found practically available. The various methods suggested resolve themselves into four principal classes—1st, the use of chemical antiseptics ; 2d, desiccation or drying ; 3d, exclusion of air ; and 4th, refrigeration or exposure to cold. In many cases combinations of these classes of agencies are employed.

Chemical Antiseptics.—The typical example of these agencies and that which has been employed from very remote times is salting or curing with common salt. The salt acts chiefly by the removal of watery juices from the tissues of animal food, and in so doing it drives off a certain proportion of the nutritive ingredients. Other substances have been associated with salt, and other processes are superadded to salting with the view of

effecting a mild cure. Among the chemical agencies proposed, the most hopeful have been sulphurous acid, acetate of potash, and bisulphite of lime. The latter, as patented and employed by Messrs. Bailey & Son of Wolverhampton, has been found to be an inoffensive and efficient agent for preserving butchers' meat for short periods. Vinegar is used to a small extent as a pickle for animal substances, but largely for vegetables. Smoking depends for its efficiency partly on the antiseptic properties of the smoke, and partly on the drying and coagulation of albumen in the process.

Desiccation or Drying is a method which has been successfully practised with fish, and in tropical countries with other animal food. In S. America beef is cut into strips and exposed to the sun until quite dry and brittle, when it forms *charqui* or jerked beef, a form of food at one time introduced into this country from the River Plate, without any great success. Except for special purposes, no greater success has attended the powdered meat proposed by Dr. Hassall. Meat biscuits are prepared with powdered meat and farinaceous materials ; and Pemican (q. v.) is another form in which desiccated meat is employed. The process of drying is applied with most satisfactory results to vegetable substances, as evidenced by the compressed vegetables of Chollet & Cie. of Paris and other firms.

Exclusion of Air.—This process is a practical exemplification of the truth of the germ theory of putrefactive change, its success depending upon first heating the material to be preserved to such a degree as to kill living germs, and then hermetically sealing it in tins with the exclusion of all atmospheric air. Tinned meats, fish, soups, and stews prepared on these principles now occupy a most important position in the list of food supplies. Mutton and beef so prepared were first largely imported from the Australian colonies, but now the United States and Canada supply large quantities, while enormous supplies of salmon tinned with oil come from the Columbia River off the Pacific coast. Sardines cooked in oil is another and old-established form of food preserved by tinning.

Refrigeration.—The most recent and altogether most satisfactory process for the temporary preservation of fresh alimentary substances is found in the artificial application of cold during transit. The principle has been long known and acted on to a limited extent, as in preserving and transporting salmon to distant markets, &c., but now on a great scale it is worked with such certainty and success that fresh meat can be transported from and through tropical heat to any distance in perfect condition. The British markets are now supplied with a considerable proportion of this fresh meat from the United States by means of refrigerating appliances fitted up in the great ocean steamers. The trade was begun only in October 1875, and already it has attained enormous proportions, with the prospect of such further expansion as will materially affect the economical conditions of large classes. The ordinary method of transmission consists in sewing up the carcasses in canvas and hanging them in specially constructed chambers, which are maintained at a temperature of 37° by a constant current of cold air blown into it by a fan blast set in motion by steam. The air admitted to the chambers is cooled down to 37° by passing it over ice ; and maintained at that temperature, the meat is delivered in London quite as fresh and in as good condition as it can be shown in New York.

Preses of Meeting. In Scotland, the business of a meeting of creditors cannot proceed without a P. He has no power beyond that of constituting the meeting and preserving order in it. His vote is only that of one creditor.

Presidency, the name given by the East India Company to their settlements at Fort William, Fort St. George, and Bombay, each of which was placed under a Governor and Council, who exercised a delegated authority over the neighbouring commercial factories. Ultimately the P. of Fort William or Bengal being interpreted to include all the rest of British India which was not either Madras or Bombay, owing to the supremacy of the Governor-General, became unwieldy and has been split up into five manageable provinces, under Lieutenant-Governors or Chief Commissioners. The threefold division, however, survives in the administration of the army, and the nominal organisation of the Covenanted Civil Service ; and the three capitals are still known as the P. towns.

President of the Council is the fourth great officer of state. His office is to attend on the Queen, to propose business

at the Council table, and to report the transactions there to Her Majesty.

Pressensé, Edmond de, D.D., a French Protestant minister, born at Paris, 27th January 1824, was educated there, at Lausanne under Vinet, and at the Universities of Halle and Berlin. He settled in Paris as pastor of the Taitbout Chapel, and soon became celebrated as an eloquent, learned, and liberal preacher. In 1863 the degree of D.D. was conferred upon him by the University of Breslau. He is the author of numerous works, many of which have been translated into English:—*Histoire des Trois Premiers Siècles de l'Église Chrétienne* (4 vols. 1858–61; Eng. trans. Edin. 1862); *Jésus-Christ, son Temps, sa Vie, son Œuvre* (1866; Eng. trans. Lond. 1866, 3d ed. 1869); *Discours Religieux* (1859; Eng. trans. Edin. 1864, Boston 1867); *L'Église et la Révolution Française* (1864; Eng. trans. Lond. 1869), and *Études Évangéliques* (1867). P. is the founder of the *Revue Chrétienne*, and the *Bulletin Théologique*.—**Madame de P.**, wife of the preceding, is favourably known as a writer of religious and educational works.

Press, Freedom of the, is a phrase used to describe immunity from the official censorship which was formerly exercised over publication. Soon after the discovery of Printing (q. v.) it was seen that the P. was likely to become a powerful instrument in the formation of opinion, and both kings and priests tried hard to keep it under safe control. Acts were passed conferring a monopoly of publication on certain parties, who required government sanction before they could issue a line. In England, Henry VIII. was as tyrannical in this as in other respects. No more would the Puritans in their hour of triumph tolerate opposition. As they shut up the playhouses, so they exercised a stern censorship over the P., and the genius of Milton pled in vain for 'the liberty of unlicensed printing.' The Restoration enforced the censorship with increased rigour, but with diminished regard to public morality. In 1693 the House of Commons voted the abolition of official or Government censorship of the P., and since that date it has been unknown in Great Britain. In most parts of Europe it is still practically in force, for although no formal surveillance *prevénu* to publication may exist, yet the authorities do not scruple on occasion to seize and confiscate newspapers, pamphlets, or books which they choose to consider objectionable, and to prosecute authors and publishers for the expression of political or religious sentiments. The only countries in the world where the principle of the 'freedom of the P.' is frankly and absolutely accepted are Great Britain (including her colonies) and the United States. Although the P. is free from official censorship, it is not exempt from the authority of law. One is at liberty to publish what he likes, but he must take the consequences. If he outrages public morality by obscenity, or inflicts in any way malicious injury on another's character, he may be prosecuted—in the former case criminally, in the latter civilly. In this respect the usage of the United States permits much greater latitude than is allowed in England. See LIBEL, and OBSCENE PUBLICATIONS.

Pressing to Death. See PEINE FORTE ET DURE.

Pressirostres, a group of *Grallatorial* or Wading Birds, in which the bill is of moderate length, and has its tip compressed. The legs are long, but the toes are short, and most frequently connected by membrane at their bases. The great toe may be rudimentary or wanting. The wings are well developed. To the P. belong the bustards (*Otidæ*), the plovers (*Charadriadæ*), lapwings, pratincoles, &c.

Prest'er John is the name given by the Europe of the Middle Ages to a supposed Christian potentate in the heart of Asia. About the beginning of the 11th c. it was reported that a king beyond Persia and Armenia had been met by the spirit of a departed saint in the depths of a forest, that the king had been converted, and that his subjects, to the number of 200,000, had been commanded to adopt the Christian religion. In the 13th c., some Nestorian priests asserted that he was Jung Khan, a Tartar chief in the Karakorum range, who was slain in 1202 by Genghis Khan. Giovanni Carpini, a Franciscan friar engaged on a mission to the grandson of Genghis in 1246, did not discover this Christian potentate, but supposed him to live still further eastward. As late as the 15th c., P. J. was searched for by the Portuguese, who had reached India by the Cape of Good Hope. Mosheim conjectures that he may have been a Nestorian

priest who gained a throne in Eastern Tartary. Some have supposed him to be merely the Grand Llama. P. J. was supposed to govern his people as a priest, after the patriarchal fashion; and hence his name. See Father Rubruquis' account of his search at the instance of St. Louis (1253), in Purchas' *Pilgrims*; Assemani's *Bibliotheca Orientalis*; *Curious Myths of the Middle Ages*, by S. Baring-Gould (new ed. Lond. 1876); and Oppert, *Der Presbyter Johannes in Sage und Geschichte* (2d ed. Berl. 1870). The opinion of Gibbon that P. J. was a khan of the Keraites, a Mongol clan, is adopted by the latest writer on the subject, Mr. H. H. Howorth, in his *History of the Mongols* (1st vol. 1876).

Pres'to (Ital. fast), a direction in music. *P. assai*, very fast, *prestissimo*, as fast as possible.

Prest'on, a considerable seaport and important manufacturing centre in the county of Lancaster, on the N. bank of the Ribble, 27 miles N.N.E. of Liverpool, and 210 N.W. of London by rail. Built on an eminence 120 feet above the river, and approached from the S. by either of two main systems of railways, it presents a picturesque appearance, the lines intersecting two fine public parks, Avenham and Miller, the latter containing the Lancashire memorial statue of the late Lord Derby, one of Noble's best efforts. P. has a third park on the northern confines of the borough—Moor Park. The river is crossed by two bridges and a railway viaduct 68 feet high. The Lancaster Canal intersects the town, and the Ribble is navigable here for vessels of 400 tons. P. has five Established churches, besides Dissenting and Catholic chapels. The parish church is a Gothic structure with a tower surmounted by a spire, containing eight bells, and was dedicated to St. John at its restoration in 1723. Christ Church, in the Norman style, with two octagonal towers, was erected in 1836 and enlarged in 1852. St. Peter's (1824) and St. Paul's (1826), both in the Gothic style, were built by grants from the Parliamentary Commissioners, the former at an expense of £6500, the latter of £7000. Of the Roman Catholic churches, the finest are St. Ignatius', in the Gothic style, completed 1836, and St. Walburge's, 160 feet long by 55 feet wide, having a tower and spire 300 feet high. Among the other buildings, the chief are the Gothic townhall, reckoned one of the late Sir Gilbert Scott's best minor works, containing the Guildhall and Exchange, and erected at a cost of £60,000; the Royal Infirmary, built 1869; the Corn Exchange (one of the largest buildings in the county); the Institution for the Diffusion of Useful Knowledge, with a library (1878) of 12,000 vols.; the theatre; the House of Correction; and, in the vicinity, Fullwood Barracks for cavalry and infantry, accommodating 1500 men, and recently considerably enlarged. County constabulary buildings are now (1878) being erected at a cost of £20,000. P. has several public libraries, one weekly and two bi-weekly newspapers, and returns two members to Parliament. It adopted the Free Libraries Act in 1878. The chief manufacture of P. is cotton, there being in the town 90 cotton-mills, which in 1871 employed 8271 men and 12,023 women. Latterly the cotton trade has shown signs of falling off, and attention has again been drawn to the capabilities of the river, which at an outlay of some £100,000 for docks, dredging, &c., might be rendered navigable for vessels of 500 tons. Shipbuilding is an important industry; in 1877, 20 vessels, from yachts of 10 tons to ocean-going steam and sailing ships of 500 tons, were built. Linen manufacture is carried on, besides tanning, malting, brewing, rope-making, shipbuilding, and brass and iron founding. In 1876 there entered the harbour 335 vessels of 24,427 tons, and cleared 195 of 14,005 tons. The gross amount of customs revenue received in 1876 was £55,858, and the value of total imports of foreign and colonial merchandise £20,421. Pop. (1871) 85,427. P., popularly styled 'Proud P.', is supposed to have derived its name from the number of religious houses it formerly contained. It was held by Tostig, brother of Harold, and was partly destroyed by Robert Bruce in 1322. Its devotion to the Stuarts led to its capture by Fairfax in the Civil War, and to its being held, unsuccessfully however, by Foster in 1715. The town has received fourteen royal charters, the first in the reign of Henry II., and the last in that of George IV. P. is the birthplace of Richard Arkwright (q. v.). See C. Hardwicke's *History of the Borough of P. and its Environs* (Prest. 1857).

Prestonpans', a coast village of Haddingtonshire, Scotland, near the W. boundary of the county, 3 miles E. by N. of Mussel-

burgh, and 9 E. of Edinburgh by the North British Railway. It was formerly a place of greater industrial importance, but now only produces a light table-beer, and a considerable quantity of oysters and salt. Salt-pans are said to have existed here since the 12th c. Pop. (1871) 2064. The battle of P. was fought in the vicinity on the 21st September 1745. It consisted of a single charge of the Highlanders under Prince Charles, by which a fully-equipped English force, 2000 strong, led by Sir John Cope, was broken and cut to pieces, while the victors, with the trifling loss of 130 men, were left in possession of the costly appointments of a complete army. The victory had the effect of at once doubling the force of the Jacobites. A brilliant description of the battle is given in *Waverley*.

Pretence, **Shield of**, or **Escutcheon Surtout**, a small shield *pretended* or placed on the centre of another shield. A wife who is an heiress usually wears the arms of her own family on a small shield of P. It is also used to display the proper arms of elective sovereigns in 'surtout' over those of their dominions. From 1801 to 1837 the arms of Hanover were placed on a S. of P., covering the centre of the royal arms of Great Britain and Ireland.

Pretoria, the capital of the Transvaal territory, S. Africa, is situated in 25° 50' S. lat., 28° 40' E. long, 1050 miles N.E. of Capetown. It derives its name from Pretorius, one of the Boer leaders (see TRANSVAAL), and is a thriving place, well-built and with a considerable trade. Since the annexation of the Transvaal by Great Britain, the progress of P. has been so rapid that its population can only be approximately stated. It is probably (1878) 5000. P. is the see of a Bishop, who was consecrated in 1878. The surrounding district is very fertile, being capable of producing wheat, tobacco, indigo, coffee, cotton, and the sugar-cane. Coal and other minerals are also found within it.

Prévost-Paradol, Lucien Anatole, a French journalist and critic, was born at Paris, August 8, 1829, studied at the Collège Bourbon and the École Normale, and in 1851 obtained the Academy prize for rhetoric by his *Eloge de Bernardin de Saint-Pierre*. In 1855 he was appointed to the Chair of French Literature at Aix, but gave it up in the following year to become editor-in-chief of the *Journal des Débats*. In that capacity he wrote countless leaders under the Bonapartist régime, consistently advocating the establishment of an Executive submitting in good faith to a Parliament elected by fair means. He made two unsuccessful attempts to obtain a seat in Parliament. In 1864 he published his *Études sur les Moralistes Français*, which contain much delicate and penetrating criticism. He was elected in the following year to the Academy. P. lectured with great éclat at the Philosophical Institution, Edinburgh, in 1869, the result being published in his English volume, *France*. He accepted the office of envoy to Washington in 1870, where on the outbreak of the Franco-Prussian War he committed suicide, July 19, 1870. In 1877 a son did the same thing at Paris. P. was one of the most temperate and well-informed of French journalists, and had the rare distinction of knowing something about English life.

Priamus (Gr. 'ransomed'), Laomedon's son and successor in the kingship of Troy, changed his name from Podarces ('swiftfoot') to P., because he alone of Laomedon's six sons was ransomed by Hermione from the vengeance of Heracles. By Arisbe he was the father of Æsacus, and by his second wife Hecuba, of Hector, Paris, Cassandra, and sixteen other children. He aided the Phrygians in their war with the Amazons, but took no active part in the Trojan War, nor does Homer make any mention of his death. Later writers say that he was slain by Pyrrhus at the altar of Zeus Herceus.

Price, Bonamy, born in Guernsey, May 22, 1807, entered Worcester College, Oxford, gained a double first in classics and mathematics (1829), became an assistant master at Rugby (1831), and was appointed Professor of Political Economy in the University of Oxford (1868). He is author of *The Anglo-Catholic Theory* (1851), *The Principles of Currency* (1869), *Currency and Banking* (1876), *Chapters on Practical Political Economy* (1878), &c., and has been a frequent contributor to the *Edinburgh* and other reviews.

Price, Richard, was born at Langeinor, Glamorganshire, February 23, 1723. In his eighteenth year he proceeded from a Dissenting seminary at Talgarth to Coward's Academy in London,

was private chaplain to a Mr. Streathfield of Stoke Newington (1743-56), and afterwards officiated as pastor in various Presbyterian meeting-houses—at Hackney, Newington Green, Edmon-ton, &c. He became a fellow of the Royal Society (1765), was created D.D. of Glasgow (1769) and LL.D. of Yale College, Connecticut (1783), and received the freedom of the city of London (1776). P. died in London, March 19, 1791. Howard, Priestley, and Franklin were among his friends, and Pitt is said to have taken many hints from his financial and political writings. These included the *Treatise on Reversionary Payments* (1769), *Observations on Civil Liberty and the Justice and Policy of the War with America* (1776), a work which gained its author an immense popularity in the revolted colonies; *An Essay on the Population in England and Wales* (1779), and *The State of the Public Debts and Finances* (1783). As a metaphysician P. combated both the empiricism of the school of Locke, and the materialism and 'philosophical necessity' of Priestley, and himself upheld the twofold origin of human knowledge, in his *Review of the Principal Questions and Difficulties in Morals* (1758), Sermons, and sundry pamphlets. See the Memoirs by his nephew William Morgan (Lond. 1815).

Prichard, James Cowles, the founder of scientific ethnology, was born at Ross, in Herefordshire, February 11, 1786, and studied medicine in Bristol, London, and Edinburgh, at the last-named place selecting as the subject of his M.D. thesis the 'Variety of the Human Race.' He commenced practice at Bristol in 1810, and there towards the close of 1813 brought out his celebrated *Researches into the Physical History of Mankind*, in which, whilst upholding the original unity of the human species, he advanced the theory that the first pair were blacks, and that civilisation has been the operative cause in the production of white varieties. The results of a study of the Teutonic and Celtic languages, of Greek, Latin, Sanskrit, and Hebrew, were incorporated in the second and third editions (1826, and 5 vols. 1836-47), in which P. ably demonstrated the importance of philology in ethnological investigations. In his *Eastern Origin of the Celtic Nations* (1831), he anticipated several of the discoveries of Zeuss, and his *Analysis of Egyptian Mythology* (1823; enlarged ed. 1838) established his reputation as an Egyptologist. The *Natural History of Man* (1843; 4th ed. 1855) was a popular résumé of the *Researches*. Meanwhile P., far from neglecting his profession, filled various important posts in the Bristol hospitals, and published a large number of medical treatises—*On Diseases of the Nervous System* (1822), *On Insanity* (1835), *On the Different Forms of Insanity in Relation to Jurisprudence* (1842), &c. He was also a frequent lecturer and contributor to scientific journals, a zealous member of the Aborigines' Protection Society, and one of the chief founders of the Bristol College. In 1844 he was appointed a Commissioner in Lunacy, and removed to London, where he died, December 22, 1848, being at the time of his death a M.D. of Oxford, a fellow of the Royal and Geographical Societies, and a member of the Institute of France, the Vienna Academy, and other learned bodies. See T. Hodgkin's *Biographical Sketch of James Cowles P.* in the *Edinburgh New Philosophical Journal* for October 1849.

Prickles (in Botany). See HAIRS.

Prickly Pear, or **Indian Fig**, is the name given to the genus *Opuntia*, belonging to the Cactus family, and consisting of about 150 species, inhabiting hot arid districts in America. All are more or less fleshy when young, have erect or decumbent branching stems, the branches consisting of flat, convex, or round growths joined end to end, and are generally armed with strong sharp spines. Brilliant-coloured flowers arise from the branches, followed by pear or egg shaped succulent fruits. Several of these remarkable plants have been introduced from America, and are now spread over a large portion

Opuntia vulgaris.

of the warmer regions of the Old World; e.g., *O. vulgaris*, a native of Central America, northward to Georgia, and southward to Peru, is thoroughly established in S. Europe, N. Africa, and the Canaries, its almost smooth fruit forming an article of food; *O. tuna*, belonging to Central America and the West Indies, attaining a height of 20 feet, is abundant in parts of Europe, Asia, Africa, the Canary Isles, &c., and fifty years ago the cochineal insect, which feeds on the plant, was successfully introduced by Bertholet into the Canaries, where it has since formed an important article of trade. The sweet juicy fruit is largely used for food. *O. ficus Indica*, another species with edible fruit, is also widespread. A dye is prepared from the pulp of some of the *Opuntias*, while some of the species with strong spines are commonly used for constructing impenetrable hedges, as also barriers against forest fires. In parts of India *O. Dillenii* has become, through distribution by birds, an intolerable nuisance. The specific names and characters of the plants constituting this genus are at present in much confusion.

Pri'deaux, Humphrey, D.D., born at Padstow, in Cornwall, May 3, 1648, passed from Westminster School to Christ Church College, Oxford (1668), and his *Marmora Oxoniensia* (1675) having attracted the attention of Lord Chancellor Finch, was by him presented to the rectory of St. Clement's, Oxford (1679). He was installed a prebendary of Norwich (1681), held in succession the rectories of Bladen with Woodstock, Oxfordshire (1682), and Saham-Toney, Norfolk (1686), became archdeacon of Suffolk (1688), vicar of Trowse (1696), and dean of Norwich (1702), and died in that city, November 1, 1724. Among P.'s works were *The True Nature of Imposture fully Displayed in the Life of Mahomet* (1679); *Tythes* (1710); and *The Old and New Testament Connected in the History of the Jews and Neighbouring Nations* (2 vols. 1715-17; ed. by A. M'Caul, 2 vols. Lond. 1845), a profound and scholarly compendium of information, which has been translated into French, German, and Dutch. A Life of P., prefixed to some posthumous tracts and letters, appeared in 1748; and his *Letters to John Ellis, sometime Under-Secretary of State*, were edited for the Camden Society by E. M. Thompson (1875).

Pri'deaux, John, born at Stowford, Devonshire, September 17, 1578, entered Exeter College, Oxford, as a servitor (1596), obtained a fellowship (1602), took orders (1603), and was elected rector of his college (1612). In 1615 he became Regius Professor of Divinity, canon of Christ Church, and rector of Ewelme, and in 1641 was consecrated to the see of Worcester. The outbreak of the civil war, and P.'s adherence to the king, lost him its revenues, and he was forced to find bread for himself and his children by the sale of a precious library, 'becoming,' says Gauden, 'a *verus librorum helluo*.' He died at Bredon, in Worcestershire, July 12, 1650. Besides *Tabule ad Grammaticam Græcam Introductorie*, P. published various treatises, collected in his *Opera Theologica Omnia* (Zurich, 1692).

Priessnitz, Vincenz, born at Grafenberg, in Austrian Silesia, October 5, 1799, was the son of a farmer and himself engaged in agriculture. Having cured himself of a broken rib by the constant application of cold water, he extended the treatment to the ailments of his neighbours, and gradually developed a regular system of Hydropathy (q. v.). In 1833 he gave up farming, and thenceforth devoted himself to the great water-cure establishment at Grafenberg (q. v.) till his death, November 28, 1851. See Selinger, *V. P.* (Vien. 1852).

Priests (Old Fr. *prestres*, contraction of Lat. *presbyteri*) are a class of men who have always been created by a tendency of the human mind in connection with worship of a deity. The first form of worship among men in an uncivilised state is always that which is prompted by fear and awe. In ignorance of the order of nature, they believe all its phenomena to be directed by the arbitrary will of beings swayed by the same feelings and impulses as themselves, and, overlooking the beneficent side of nature, or ascribing it to good deities who need no prayers, they live in terror of the unfavourable aspects, or in other words, of the manifestations of the displeasure of the irascible or evil beings who have them at their mercy. But supposing also that these deities may be propitiated on the same principle as themselves, they bring them offerings of the best they have; and thus arises the system of Sacrifice (q. v.). The most primitive manner of offering sacrifice is for each man to

present his own gift to the deity for himself, as was done, according to the Hebrew Scriptures, by Cain and Abel, or for himself and family, as was done by Noah, Abraham, Jacob, Job, &c. The patriarch was priest for the tribe (cf. Gen. xii. 8, xviii. 23, xxvi. 25, xxxiii. 20), or the king for the nation (cf. 2 Sam. vi. 12-18; 1 Kings iii. 15). It is only another step in the same direction now, when certain persons are appointed by the worshippers to offer their prayers and sacrifices, as being more acceptable than themselves. These are the P., who are thus in the position of mediators between gods and men; the representatives of the latter in things pertaining to God, and, on the other hand, the interpreters of the gods, teaching men all the ceremonies used in divine worship. In virtue of these duties they were honoured with the next place to the kings or chief magistrates, and in many places wore the same habit.

Perhaps the most elaborate and thoroughly organised priesthood in the ancient world was that of the Egyptians, among whom the P., along with the military men, held the highest position in the country after the royal family. To one or other of these two professions the king always belonged, and when he belonged to the military it was his duty on ascending the throne to be instructed in the mysteries of the religion, and the various offices of the chief priest. The view that has hitherto prevailed regarding the priesthood among the Israelites is, that the whole system, with the High Priest (q. v.) and the Levites (q. v.), and all their respective duties and maintenance, was appointed and regulated by Moses in the Pentateuch, with the admission that certain items of the Hebrew ritual had been borrowed from the Egyptians, or at least corresponded with theirs; e.g., shaving of the body (Num. viii. 7), the wearing of linen garments (Exod. xxviii. 39; Ez. xlv. 18), the practice of going barefooted (the Egyptian priest wore sandals of byblus), multiplied ablutions, a public maintenance, besides a share of the flesh of the victims offered, hereditary succession, and one high priest (Herod. II.). But regarding the priestly legislation of the Pentateuch, modern criticism is beginning to hold some very revolutionary opinions. It has been noticed that there is a remarkable distinction between Deuteronomy and the Levitical legislation in Exodus, Leviticus, and Numbers. According to the latter the tribe of Levi was appointed to minister to the P., the sons of Aaron (Num. iii. xviii.), they had certain cities assigned to them out of each of the tribes (xxxv.), and also the tenth, not only of all vegetable produce, but of the annual increase of the flocks and herds; such tithes, diminished by a tenth paid to the P., to be eaten by the Levites in whatever town they lived. Deuteronomy, on the other hand, knows no difference between Levites and P.; they are 'the P. the Levites,' 'the P. the sons of Levi,' and allows the Levites to do things which the Levitical law allowed only to the priests (Deut. xvii. 9, xviii. 1, xxi. 5). They have no cities of their own, but are poor and houseless (xiv. 27, 29, xvi. 11, xviii. 1-8, xxvi. 12). Any provision they have is the tithes of vegetable produce, from which of course nothing is subtracted for the priests, but which are to be eaten in the town where the central sanctuary was. These differences have been explained by supposing that the two accounts refer to the same system at two different periods of development, and the question of their relative priority is thought to be decided by the history. Some of the most characteristic features of the Levitical legislation are held to be ignored and even contradicted by the history—e.g., in the time of David there was not *one* high priest, but two chief P. of equal authority, Zadok and Abiathar (2 Sam. xx. 25); indeed, the first high priest named is Hilkiah in the time of Josiah (2 Kings xxii. 4). Again, the Levites seem never to have got their cities, but to have dwelt all over the country, and there is not a hint of Levitical territorial possessions; while sacrifices are mentioned as offered by a great number of persons who did not belong to the tribe—Gideon, Saul, David, Solomon, Uzziah. A strong point is made of the omission from the history of all mention of the Day of Atonement, the tenth of the seventh month (Lev. xvi. 29, xxiii. 27-32). When the Jews returned from Babylon under Zerubbabel (B.C. 538), on the arrival of the seventh month they assembled at Jerusalem and offered the sacrifices prescribed, beginning on the first day and observing the Feast of Tabernacles on the fifteenth; but there is no allusion to the Day of Atonement (Ezra iii. 1-6). Similarly, when the Law was read to the people (B.C. 445), they observed the Feast of Tabernacles on hearing the directions therefor, and also a solemn fast on the twenty-fourth, but no notice is taken of the tenth (Neh. viii., ix.). The general result arrived at by

critics who look at the history in this light is that the priesthood was only organised on the building of Solomon's temple; that the simpler system of religious and ceremonial duties in Deuteronomy is the earlier, that book in fact being virtually 'the book of the Law,' which was found by Hilkiah in the days of Josiah (about B.C. 580—2 Kings xxii.); and that the Levitical code in Exodus, Leviticus, and Numbers cannot have been completed even in the early days of Nehemiah, and may probably be assigned to about B.C. 400, corresponding to which latest development are the vision of Ezekiel (xl.-xlviii.) and the Books of Chronicles.

In the Christian Church, any idea that there was of a priesthood at first was that it consisted of all believers, Jesus Christ being the High Priest and Mediator for all. But with the development of the episcopal system the idea gradually gained ground that the Church was the same as the Old Testament theocracy, requiring a sacerdotal caste through whose mediation alone it could be established in the world. The idea that the priest actually performed sacrificial functions was fully developed in the doctrine of the Mass (q. v.). Protestants took up the position that the ministers of religion are not P. in the official sense; that all believers are P. in the only sense in which there can be such under the Gospel; and that Christ is the only Mediator between God and man. See Kalisch's commentary on *Leviticus* (Lond. 1867 and 1872), Kuenen's *Religion of Israel* (Eng. trans. 1874-75), Potter's *Antiquities of Greece* (4th ed. Lond. 1722), and Hodge's *Systematic Theology* (Edin. 1871-73).

Priestley, Joseph, son of a draper, was born at Fieldhead, near Leeds, 13th March 1733, lost his mother in his seventh year, and passed under the tuition of an aunt who had strong theological leanings. By her he was sent to school, and early distinguished himself by the ease with which he learnt languages, having, in addition to the ordinary study of classics, familiarised himself with Syriac and Arabic, German, French, and Italian. The polemical atmosphere of his aunt's home, to which local theologians crowded, induced him to give to the knottiest problems of that science a full and interested attention. After passing through a Dissenting seminary P. became a minister, and received a call to Needham Market in 1755, from which, having preached his church empty in three years, he went to Nantwich, in Cheshire. In the former place he wrote the *Scripture Doctrine of Remission*, in which he argued for the divine nature of the Scriptural revelation, whilst rejecting the doctrine of the Trinity and the Atonement and holding by the purely human conception of Christ's life. It was published in 1761, in which year he went to Warrington, where he married, still, however, devoting himself with the most fruitful industry to language, science, and politics. In 1762 appeared his *Theory of Language and Universal Grammar*, and in 1765 the *Essay on a Course of Liberal Education for Civil and Active Life*, and *Chart of Biography*. In 1766 he was made a member of the Royal Society and LL.D. of Edinburgh University, and in 1767 was called to Millhill, near Leeds. The same year appeared his *History and Present State of Electricity*, a work suggested to him by Franklin during a visit he had made to London. He next threw himself with eagerness into the study of chemistry, his mind being directed to it by the proximity of his house to a brewery. His *Observations on Different Kinds of Air* gained him in 1772 the Copley Medal. At the same time he accepted the offer to accompany Captain Cook on his second voyage of discovery, but the appointment was cancelled owing to his heterodoxy. In 1773 he was appointed librarian to the Earl of Shelburne, and next year he went abroad with him, his intercourse with the Parisian philosophes resulting in his *Letters to a Philosophical Unbeliever*, in which he developed a scheme of Christian apologetics. It was followed in 1777 by a *Disquisition Relating to Matter and Spirit*. Three years later he left the service of Lord Shelburne and took up his residence at Birmingham, where he found congenial spirits in Watt, Withering, and Bolton. Here he again pursued clerical labour and turned to theology with renewed ardour. In 1781 appeared his *Institutes of Natural and Revealed Religion*, in 1782 the *History of the Corruptions of Christianity*, and in 1786, *History of Early Opinions Concerning Jesus Christ*. P. felt himself highly honoured by being elected a French citizen because of his *Reply to Burke's Reflections on the French Revolution*; but a different sentiment was expressed by a mob of brutal fanatics, who wrecked his house, destroying his books, manuscripts, and scientific instruments. P.

then departed for London, where he took Dr. Price's church at Hackney in 1791, but in 1794 he crossed the Atlantic and settled at Northumberland, Pennsylvania. In 1802 he dedicated to President Jefferson his *General History of the Christian Church*. He died February 6, 1804. P. was a most guileless and earnest searcher after truth. His mind had an extraordinary versatility and fecundity. In the face of much misrepresentation he led a blameless life. See the *Memoirs of J. P.* prefixed to Rutt's edition of the *Theological and Miscellaneous Works of J. P.* (25 vols. Hackney, 1817-32), *Life of J. P.*, by John Corry, and a Bibliography, comprising over 300 of P.'s writings (Washington, 1875).

Priluki, a town of Russia, government of Poltava, on the Udal, 75 miles E. by N. of Kiev. It has six churches, a considerable manufacture of tobacco (Machorka kind), and a thriving trade in grain, cattle, brandy, &c. Pop. (1870) 12,878.

Prim, Juan, a Spanish soldier and politician, born at Reus, in Catalonia, December 6, 1814, rose rapidly in the army of the Christinos to the rank of colonel (1837), and as a *Progresista* aided Narvaez in his overthrow of the regent Espartero (1843). By the new government he was created count, general, and governor of Madrid, but in 1845 his opposition to Narvaez led to his arrest and condemnation to six years' imprisonment. Christina, however, pardoned him, and he held the governorship of Puerto Rico, till, being dismissed in 1848, he rejoined the opposition, and in 1853 was banished to France. He served as a volunteer in the Turkish army (1854), under O'Donnell's ministry was returned to the Spanish Senate (1858), and in the war with Morocco won by his services as commander of the reserves the title of Marquis de los Castillejos (1860). Appointed to the command of the Spanish contingents in the Mexican war of the Allied Intervention, he formed with Juarez the Convention of Soledad (1862), which measure he barely justified by his three days' defence before the Cortes. In 1864 he was banished to Oviedo on a charge of conspiracy, and after an abortive rising at Aranjuez (1866) fled to Portugal, thence to England, and finally to Belgium. From Brussels he directed the insurrection of 1868, which resulted in the flight of Isabella and in his own triumphal entry into Madrid, where he was minister of war in Serrano's provisional government, and became marshal, commander-in-chief, and president of the cabinet (1869). As such he had successively offered the vacant throne to Espartero, Prince Leopold of Hohenzollern, and Amadeus, when on December 27, 1870, he was shot in his carriage by some unknown assassins, and three days later died at Madrid. A splendid monument was consecrated to his memory in the Atocha Basilica, June 5, 1875.

Prima Donna is the chief female singer in an opera; *prima viola*, the first viola; *prima vista*, at first sight, &c.

Primary, in geology, is now applied to all rocks older than the Triassic, and is synonymous with the word Palæozoic. In the early days of geology, however, P. or *primitive* rocks included granite, gneiss, mica schist, and such like, which were looked upon as the original source of the ordinary stratified sandstones, clays, and limestones. The term *transition* rocks was then found necessary to include rocks which apparently were intermediate in character to the first two great groups. With the growth of knowledge, the terms primitive and transition were gradually abolished, and P. came to be used in the general chronological sense given above.

Primary Schools. See PUBLIC SCHOOLS.

Primate (Lat. *primatus*, from *primus* 'first'), was originally the same as a Metropolitan or chief bishop of a province. Metropolitan is now synonymous with Archbishop (q. v.); and the P. is the superior of a number of ordinary archbishops, presiding over the ecclesiastical capital of a country. In England there are two primates, the Archbishops of Canterbury and York, who by a nice distinction have the titles P. of All England and P. of England respectively. The title of P. had been applied to these two from there having been formerly other archbishops; as there were of Lichfield (in the 8th c.) and of St. David's till 1148. There are also two primates in Ireland—the Archbishop of Dublin (P. of Ireland), and the Archbishop of Armagh (P. of All Ireland).

Primates, the division of Mammalia formerly constituted by Linnæus to include man and the quadrumana, or

Apes. This division has been revived, along with the Cheiroptera or Bats—minus the bats—in recent zoological classifications. The differences between the human and ape type are recognized by the division of the *P.* into four subdivisions—*Prosimia* (Lower Quadrumana, such as the Lemurs, &c.); *Simia* (the Quadrumana proper); and *Bimana* or *Anthropoidea* (man). See **QUADRUMANA**, **MAN-MONKEY**, &c.

Primaticcio, Francesco, the founder of the Fontainebleau school of painting, was born at Bologna in 1490, and became a pupil of Giulio Romano, whom he helped in the decoration of the Palazzo del Tè at Mantua. In 1531 Duke Federigo Gonzaga recommended him to François I. of France, who, after employing him to collect statues and casts, bestowed on him the office of court-painter, with the abbacy of St. Martin de Troyes. He was appointed Superintendent of the Royal Buildings by François II. (1559), and died in 1570. The grace and harmonious colouring of P.'s allegorical frescoes at Fontainebleau go far to redeem their tasteless and often obscure subjects and their frequent faultiness of design. Other works by him are the 'Continence of Scipio' in the Louvre, 'Moses striking the Rock' at Vienna, and 'An Angel showing a Young Man the way to Heaven' at Darmstadt.

Prime. See **CANONICAL HOURS**.

Primogeniture is the rule of law under which the eldest son of a family, or person in his right, succeeds, on the death of the father, to his real estate. The right does not apply to personal property. See **BIRTHRIGHT**, **HEREDITARY RIGHT**. Regarding female succession, see **COPARCENARY**.

Primrose (*Primula*, from Lat. *primus*, in reference to the early flowering) is the type genus of *Primulaceæ*, consisting of about 50 species of perennial herbs ranging through the temperate, arctic, and mountainous regions of the northern hemisphere, and again appearing in Chili and Fuegia. *P. vulgaris*, the favourite spring wild-flower in England, decking the copses, hedgebanks, and pastures with a profusion of pale yellow blossoms, grows also in most countries of Europe as well as N. Africa, and in affectionate remembrance of home scenes has been carried by British emigrants to southern colonies. It is subject to much variation, and between it and *P. veris*, the cowslip, a number of hybrid forms occur, which are often called 'oxlips.' *P. elatior*, the real oxlip, is in England very rare. A pretty species named *P. farinosa* has its leaves covered on the under side with a mealy substance, and its umbels of lilac flowers with a yellow centre have originated for it the name Bird's-eye *P.* Very similar to it, but of more northern range in Britain, is the arctic *P. Scotica*, found in Caithness, Sutherland, and Orkney. *P. helvetica*, *P. nivalis*, *P. viscosa*, and *P. integrifolia* are European species that find a place in gardens. *P. marginata*, when planted in shady situations, is lavish of its pale and delicately beautiful flowers. The curious *P. verticillata* and the splendid *P. sinensis* are inmates of greenhouses amongst horticulturists; and *P. japonica*, a recent introduction, is aptly termed the queen of primroses. See **AURICULA**, **COWSLIP**, and **POLYANTHUS**. The flowers in *P.* are usually dimorphic, having long styles, and anthers deep-seated in the tube—or the reverse of these conditions; for perfect fertilisation, the pollen from the deep-seated anthers has to reach the stigma of the short-styled plant—and *vice versa*. The elucidation of this phenomenon was the beginning of Darwin's great publications on plant life.

Primulaceæ is a natural order of about 200 species of perennial or rarely annual herbs, of which representative genera have already been given under **PIMPERNEL** and **PRIMROSE**. A few species occur in the southern countries of S. America, otherwise the distribution is confined to the temperate and arctic zones, and Alpine situations in the northern hemisphere. The properties are unimportant. In collections of 'Alpine plants' various species of *Androsace*, *Cyclamen*, *Soldanella*, and *Primula*

Primula auricula.

are much esteemed; and other genera, such as *Lysimachia* and *Dodecatheon*, furnish good hardy garden plants. See **HOTTONIA**.

Primum Mobile. See **PTOLEMAIC SYSTEM**.

Prince (Lat. *princeps*, from *primus*, 'first,' and *caput*, 'a head'), a title attached at different epochs to widely different dignities. Under the Roman republic, the citizen whose name was inscribed first by the censors on the senatorial roll was styled *Princeps Senatus*, and this title was subsequently assumed by the emperors. In the Middle Ages the chief officers of state termed themselves princes, and their territories principalities, whilst at the present day the title of P. is borne by younger members of the royal families of Europe, by a few inferior potentates, as the Princes of Monaco and Orsini, and by the descendants of the marshals whom Napoleon elevated to the princely rank—the so-called 'Princes of the Holy Empire.' The eldest son of a reigning sovereign is usually distinguished by a special territorial title, being styled in England P. of Wales, in the Netherlands P. of Orange, in Spain P. of the Asturias, &c., but in Germany and Austria he is simply the *Kronprinz*, as in France he was the *P. Impérial*. In England, dukes and marquises are princes only in ceremonial language; and in Germany, members of the royal family or of ruling houses dating from the Holy Roman Empire alone are *Prinzen*, a *Fürst* (which we also translate by 'P.') ranking after a *Herzog*, and holding no sovereign dignity.
